This is a trivial illustration; reference to the papers of Prof. W. W. C. Topley [9] suggests far more important applications. This is, indeed, the point to which I have been bringing you by devious paths. I said at the outset that my conception of the statistical method in medicine has changed in the last 20 years; this is especially so with regard to the bearing of statistical method upon experiment. I used to see in the statistician the critic of the laboratory worker; it is a rôle which is gratifying to youthful vanity, for it is so easy to cheat oneself into the belief that the critic has some intellectual superiority over the criticised. I do not think even now that statistical criticism of laboratory investigations is useless, but I attach enormously more value to direct collaboration, the making of statistical experiments, and the permeation of statistical research with the experimental spirit. In this matter Prof. Topley is the pioneer. Topley has endeavoured to study *under laboratory conditions* the genesis and development of epidemics. Down to his time the subject has been examined in absolutely isolated fields. We have had on the one hand historians, public health administrators, statisticians wholly occupied with the records of occurrences of epidemic disease in nature; we have had on the other laboratory workers sedulously investigating the biological properties of the *materies morbi* and searching out the immunological properties of the living tissues of men and other animals. Between these two groups there has been little coöperation, the sanitarians have often drawn on themselves the contempt of the trained laboratory worker by a certain rashness and even amateurishness in their exploitation of laboratory results; the laboratory workers have sometimes displayed an equal crudity in their interpretations of the facts of sanitary history. It has not been recognised that the complex of phenomena in the world of humanity is so vast and the accuracy of the historical record so poor that there is little hope of solving any epidemic problem by the statistical or historical analysis of records alone; there is equally little hope of solving it by the minutely accurate, small scale experiment which has been the fashion of the laboratory worker. We must observe a "population" less complex, less exposed to the play of varied influences than the world of men and women, but much more complex than any laboratory investigator before Topley and the staff of the Rockefeller Institute had dreamed of. But, from the moment that we envisage the possibility of studying an artificial epidemic, we are faced with the need of much greater knowledge of the physiology of the animals we shall use as our material, and of a notation to describe the results.

Topley has worked with populations of mice and has reached such tentative conclusions as these:—

> "We were thus forced to the conclusion that mice, among which an epidemic was spreading, were subjected to an increased risk of death if they were allowed to mingle with normal members of their own species. *This conclusion* was confirmed by measuring the rate of extinction of a mouse population, among which a given bacterial disease was spreading, according as it was kept in isolation or was subject to a steady immigration of susceptible individuals of the same species. . . . It would seem, *then*, that the survivors from one epidemic, though in apparent health, are carrying the parasites which caused the disease from which their companions died, and that when they come into contact with any considerable number of susceptible individuals of their own species a process is set up which leads to a fresh outbreak of disease. It seems clear also that these mice which have passed through one epidemic wave are now possessed of some increased powers of resistance to the disease in question, for they tend regularly to outlive the new arrivals in the cage. But this resistance is relative and not absolute, for they tend to die during the later stages of the new epidemic which they themselves have started. . . . We are led to the view that the immigration of healthy but susceptible individuals into a population which has recently emerged from a considerable outbreak of disease is just as dangerous to the community they enter as it is to themselves" (op. cit., pp. 65–68).

Topley reaches these conclusions by treating his data on the lines of a life or survival table; it is evidently the proper way to treat them. Before we can fully profit by experimental studies of epidemics we must learn much more about the course of life, apart from epidemics, in our population. While "laboratory animals" are only used as living culture media or animated test-tubes, people have not bothered about their sociology! In Rössle's [10] vast *referat* on *Wachstum und Altern* one seeks in vain for *any* precise observations of the course of life in animals other than man. He cannot go beyond the cautious conclusion that in such animals as have been "tolerably" (leidlich) studied one finds "a uniform decay of many organs and tissues" rather than a senile central nervous system in a young body (op. cit., p. 569). We have a survival table for one animal other than man—*Drosophila melanogaster!*—made by Prof. Raymond Pearl [11] (*Metron*, 1923, ii., 697).

We know very little of the trend of life in mice. Yet this is important. Prof. Pearl suggests that we can make an exact comparison between the life-table of a fly and the life-table of a human population by merely altering the unit; one year of human life is equated to 1·1279 days in the life of a fly. Suppose we take the common opinion that the average life of a mouse is two years, then a year of human life is equivalent, taking an average human life as 50 years, to about a fortnight, so by that method of reckoning an attack of, say, mouse typhoid ending in recovery is a matter of (humanly speaking) years. We know what a different business, say, a pneumococcal pneumonia is between 40 and 50 and between 20 and 30 from the prognostic standpoint. We have not sufficiently considered the possibility that this factor may be of importance in populations of laboratory animals. We *must* consider this and many other histological factors on statistical lines, with the notation of the life-table and Graunt's shop arithmetic. Such is my answer to the first part of the second question proposed so long ago that you have forgotten it. Using no statistical methods which would not have been intelligible to John Graunt, applying those methods to the controlled populations handled by Topley, it is probable, it is almost certain, that we shall reach a clearer insight into the phenomena of epidemic disease than generations of unintegrated experimental and statistical work have achieved; armed with that knowledge, we may be able to interpret the record, both minute and defective, of human history.

The New Statistical Calculus.

The second part of my question, what we are to hope from the new statistical calculus, I have left no time to answer fairly. I will only quote from an old book. Oesterlen[12] said:—

> "It may be regarded as the established result of experience that scrofula, rachitis, the formation of tubercles, and similar affections, occur most frequently in the children of the poor. Statistical indications of the same circumstance are also not wanting, but our insight into its immediate or remote causes is not furthered by them because they merely give us a certain total result, and do not enlighten us, for instance, as to whether those children fell sick from bad food and air, or from want of care, from hereditary predisposition, from bodily malformations, or from a syphilitic taint derived from their parents. All this we may hope to learn with more certainty as statistical comparison becomes more accurate and is better able to isolate some particular influence and determine its action upon any given case."

Oesterlen's prevision has been fulfilled. Even the most convinced adherents of the environmental as opposed to the genetic origin of ill-health will hardly deny that, for instance, Prof. Karl Pearson's investigations of the factors influencing the ill-being or well-being of children have given us a clearer insight into the rôles of different possible and probable causes of ill-health. Nature *does* present us with skeins not to be unravelled by the most habile experimenter, cases where the A, the B, and C *cannot* be studied in isolation. In these instances, the modern statistical calculus of correlations is, not indeed a key to all the mythologies, but a useful, an invaluable, tool.

As the immediate collaborator of the experimenter, collaboration implying that he will take pains to understand the work of the experimenter, even to do some of it himself, the medical statistician has, I submit, an important part to play in modern research. In the investigation of such phenomena as are, at first view, too complex for experimentation, he can do service, chiefly, I believe, in detecting by his calculus factors which might be made the object of a simpler but more exact experimental investigation. When I first took an interest in these matters, more than 20 years ago, there was some tendency to treat the statistician or biometrician as a pariah, and he acquired the virtues and vices of a minority, a certain courage and a certain trick of over-emphasis —they always characterise a fighting minority. Now, statistics and statisticians are perfectly respectable; there may even be a risk of putting the claims of the statistical expert too high. The time may perhaps come when a brilliant young mathematician, building higher on the mathematical foundations laid by Karl Pearson, will assert that in medical, or any other biological research, the judgment of the biometrician must be final; he must be the ultimate court of appeal. If that time comes, I shall be found enlisted under the banner of Sir Almroth Wright, and shall quote to the would-be dictator the words of Macaulay:—

> "I tell the honourable and learned gentleman, that the same spirit which sustained us in a just contest for him will *sustain us in an equally just contest against him.* Calumny, abuse, royal displeasure, popular fury, exclusion from office, exclusion from Parliament, we were ready to endure them all, rather than that he should be less than a British subject. We never will *suffer him to be more.*"

The statistician must be the equal not the predominant partner.

OBSERVATIONS ON THE USE OF INSULIN.

By D. MURRAY LYON, M.D., F.R.C.P. Edin.,
CHRISTISON PROFESSOR OF THERAPEUTICS, UNIVERSITY OF EDINBURGH.

Insulin is employed in diabetes with the object of making good a deficiency in the supply of the natural hormone of the pancreas in these cases. The ideal method of administering the drug would be to imitate as closely as possible the normal supply of the substance in the body. Unfortunately we are ignorant of the rate of secretion of insulin by the pancreas and whether the process is continuous or intermittent. It would seem probable, however, that a small quantity of the hormone is constantly being poured out, and that an extra amount becomes available when required, for example, after a carbohydrate meal has been taken. In any case the supply of insulin in normal individuals is such that the blood-sugar remains about 0·1 per cent. and is only raised to a slight extent by ingested carbohydrates. Diabetic subjects respond to carbohydrate food less perfectly, the lack of insulin allowing a much greater and much more prolonged increase in the blood-sugar, the percentage often rising to 0·3 or 0·4. The mildest cases of the disease show this exaggerated hyperglycæmia only after feeding, and their blood-sugar may return to the normal level between meals and during the night. In such patients a sample of blood taken before breakfast will give a normal reading. When the case is more severe, the phase of hyperglycæmia persists longer after each meal and may not pass off completely during the night. The fasting blood-sugar level is therefore high, and glycosuria is present during the whole 24 hours. Such a patient starts his day with a handicap; the blood-sugar, which already stands above the renal threshold, is further raised by each meal, and does not have time to subside far before the next food is taken. It will be seen, then, that the morning blood-sugar value represents the lowest point in the daily cycle in such cases, and when the patient is on a standard diet, the height of the fasting sugar level gives a rough guide to the severity of the case *at the moment.*

Effect of Diet on Fasting Blood-sugar.

The character of the diet that the patient is taking is also a factor in determining the height of his fasting blood-sugar. When he passes from a more meagre to a larger diet, the level of the fasting blood-sugar gradually rises from day to day until a new equilibrium is reached. The full effect may not be evident for some days after the food increase has been made. In the same way reduction of the food intake lowers the fasting sugar levels, a principle that has been made use of in the well-known Allen system. Again, the new level only becomes definitely established after a certain interval. Some patients become sugar-free on slight restriction of diet, others must be deprived of food for two or three days before the blood-sugar falls below the renal threshold level. From this it follows that the state of the blood-sugar and the quantity of sugar lost by the kidney only correspond to the food intake when the patient has been on a constant diet for several days. This fact serves to explain the frequent failure to find a relationship between the food intake and the degree of glycosuria.

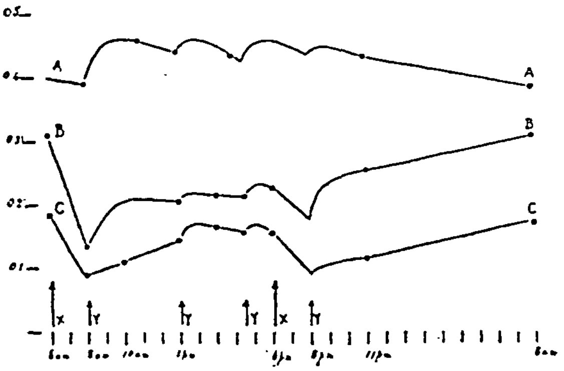
The slow change to a new level is doubtless due to liberation of stored carbohydrate.

The following figures, obtained from a moderately severe case of diabetes, give an idea of the fluctuation in blood-sugar values throughout the day:—

Observation	A	B	C	D	E	F
Hours	0	3	5	8	15	24
Sugar per cent. ..	0·39	0·50	0·44	0·43	0·43	0·38

A is the fasting blood-sugar reading taken at 8 A.M.; B was taken three hours after breakfast and should represent the maximum rise of the post-prandial curve. C and D were taken immediately before dinner and tea respectively. E was taken four hours after supper, and F is the fasting level next morning. The rises after dinner, tea, and supper were not observed but have been guessed at. (See Curve A, Fig. 1.)

FIG. 1.—*To show Changes in Blood-sugar Levels during 26 Hours.*



Ordinates show percentage of blood-sugar, Abscissæ hours. Insulin given to Cases B and C at 6 A.M. and 6 P.M. Case A received no insulin. Meals taken at points Y. Actual observations indicated by dots.

High blood-sugars of this sort lead to considerable waste of carbohydrate by glycosuria, and are also known to aggravate the pancreatic damage. It is therefore desirable to employ insulin in such a manner as to maintain the blood-sugar about the normal level at all times. How best to do this has not been decided.

Effect of a Single Dose of Insulin in a Diabetic Subject.

Insulin given subcutaneously to a fasting patient causes a somewhat slow fall in the blood-sugar during the first half hour. This phase is followed by a much more rapid decline for the next hour or hour and a half, but after the second hour the rate of fall again slows and only a slight further diminution in concentration takes place, although the effect persists for a long time. The minimum point is reached somewhere between the third and the sixth hours, and thereafter the blood-sugar values increase once more. A return to the original fasting level would take place were not the diminishing effect of several hours of starvation superadded. The whole reaction caused by 10 units of insulin lasts more than eight hours, and in many cases the effects are still noticeable 12 to 16 hours after injection.

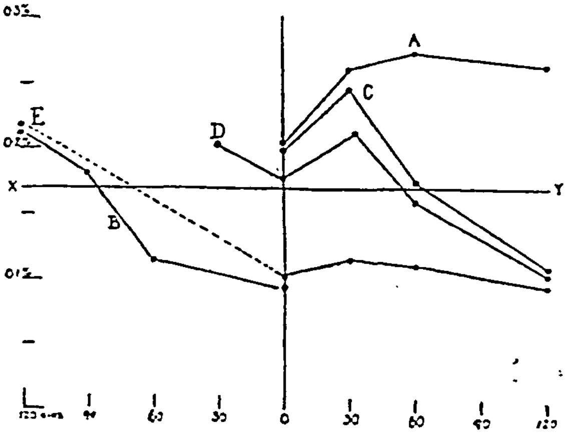
The absorption and the utilisation of insulin is an example of "consecutive reactions" (as has been shown for adrenalin).[1] The rate of removal of the insulin from the site of injection is most rapid at first, when the greatest amount of the drug is present locally, and diminishes later. The amount of the substance in the blood will rise from zero to a maximum concentration, and during this period an increasing effect (blood-sugar fall) will take place. The slow preliminary decline in the blood-sugar values means that a certain time is required for the greater part of the insulin to come into action. Attention should be given to this point in determining the interval between the injection of the drug and the giving of the food it is designed to "cover." Although the quantity of insulin administered may theoretically account for the amount of carbohydrate taken, the rate of absorption of the food might outstrip that of the drug and so upset the calculation. Clinical experience has shown that other factors must be taken into account.

Effect of Varying the Interval between the Administration of Insulin and the Taking of Food.

Little attention seems hitherto to have been given to this question, which appears to be of some importance. When a diabetic takes carbohydrate food his blood-sugar almost at once begins to increase, and rises rapidly to a considerable height. We have seen, however, that the full effect of insulin is not obtained until some half-hour or more after the injection has been given. It will therefore appear that a considerable rise of blood-sugar may take place before sufficient insulin is available to arrest the increase. During this interval glycosuria may occur even when the fasting sugar level has been normal. When the morning blood-sugar is high, as so frequently is the case in these subjects during the early stages of treatment, this loss of sugar in the urine may be of great importance. Even when the amount of carbohydrate and the quantity of insulin were so perfectly matched as to neutralise each other and the reaction commenced from a high fasting level, the subsequent blood-sugar value would still remain above the renal threshold throughout the whole absorption period, and much glucose would be lost. The use of larger doses of insulin might overcome these difficulties by hastening absorption of the drug, but this would add greatly to the expense of treatment.

Observations have been made on the blood-sugar changes and on the urine in patients taking a standard breakfast with a uniform dose of insulin *at different intervals* before the meal. The results are shown in Fig. 2. The breakfast when taken without insulin causes the typical excessive rise in blood-sugar (Curve A). If insulin is given and food is taken immediately afterwards the blood-sugar rises for a time, then falls again fairly abruptly, much earlier

FIG 2.—*To show Effect of Varying the Interval between Injection of Insulin and the Meal Following.*



A standard breakfast was given at the point 0: the figures on the abscissæ indicate minutes before and after commencing the meal.

Curve A, blood-sugar changes when no insulin was given. B, Effect of 10 units of insulin on the fasting blood-sugar. C, Breakfast and insulin taken at same time. D, Insulin given half hour before food. E, Insulin two hours before breakfast. X–Y, Normal level of renal threshold.

shall reach a clearer insight into the phenomena of epidemic disease than generations of unintegrated experimental and statistical work have achieved; armed with that knowledge, we may be able to interpret the record, both minute and defective, of human history.

THE NEW STATISTICAL CALCULUS.

The second part of my question, what we are to hope from the new statistical calculus, I have left no time to answer fairly. I will only quote from an old book. Oesterlen[12] said:—

> "It may be regarded as the established result of experience that scrofula, rachitis, the formation of tubercles, and similar affections, occur most frequently in the children of the poor. Statistical indications of the same circumstance are also not wanting, but our insight into its immediate or remote causes is not furthered by them because they merely give us a certain total result, and do not enlighten us, for instance, as to whether those children fell sick from bad food and air, or from want of care, from hereditary predisposition, from bodily malformations, or from a syphilitic taint derived from their parents. All this we may hope to learn with more certainty as statistical comparison becomes more accurate and is better able to isolate some particular influence and determine its action upon any given case."

Oesterlen's prevision has been fulfilled. Even the most convinced adherents of the environmental as opposed to the genetic origin of ill-health will hardly deny that, for instance, Prof. Karl Pearson's investigations of the factors influencing the ill-being or well-being of children have given us a clearer insight into the rôles of different possible and probable causes of ill-health. Nature *does* present us with skeins not to be unravelled by the most habile experimenter, cases where the A, the B, and C *cannot* be studied in isolation. In these instances, the modern statistical calculus of correlations is, not indeed a key to all the mythologies, but a useful, an invaluable, tool.

As the immediate collaborator of the experimenter, collaboration implying that he will take pains to understand the work of the experimenter, even to do some of it himself, the medical statistician has, I submit, an important part to play in modern research. In the investigation of such phenomena as are, at first view, too complex for experimentation, he can do service, chiefly, I believe, in detecting by his calculus factors which might be made the object of a simpler but more exact experimental investigation. When I first took an interest in these matters, more than 20 years ago, there was some tendency to treat the statistician or biometrician as a pariah, and he acquired the virtues and vices of a minority, a certain courage and a certain trick of over-emphasis—they always characterise a fighting minority. Now, statistics and statisticians are perfectly respectable; there may even be a risk of putting the claims of the statistical expert too high. The time may perhaps come when a brilliant young mathematician, building higher on the mathematical foundations laid by Karl Pearson, will assert that in medical, or any other biological research, the judgment of the biometrician must be final; he must be the ultimate court of appeal. If that time comes, I shall be found enlisted under the banner of Sir Almroth Wright, and shall quote to the would-be dictator the words of Macaulay:—

> "I tell the honourable and learned gentleman, that the same spirit which sustained us in a just contest for him will sustain us in an equally just contest against him. Calumny, abuse, royal displeasure, popular fury, exclusion from office, exclusion from Parliament, we were ready to endure them all, rather than that he should be less than a British subject. We never will suffer him to be more."

The statistician must be the equal not the predominant partner.

OBSERVATIONS ON THE USE OF INSULIN.

BY D. MURRAY LYON, M.D., F.R.C.P. EDIN.,
CHRISTISON PROFESSOR OF THERAPEUTICS, UNIVERSITY OF EDINBURGH.

INSULIN is employed in diabetes with the object of making good a deficiency in the supply of the natural hormone of the pancreas in these cases. The ideal method of administering the drug would be to imitate as closely as possible the normal supply of the substance in the body. Unfortunately we are ignorant of the rate of secretion of insulin by the pancreas and whether the process is continuous or intermittent. It would seem probable, however, that a small quantity of the hormone is constantly being poured out, and that an extra amount becomes available when required, for example, after a carbohydrate meal has been taken. In any case the supply of insulin in normal individuals is such that the blood-sugar remains about 0·1 per cent. and is only raised to a slight extent by ingested carbohydrates. Diabetic subjects respond to carbohydrate food less perfectly, the lack of insulin allowing a much greater and much more prolonged increase in the blood-sugar, the percentage often rising to 0·3 or 0·4. The mildest cases of the disease show this exaggerated hyperglycæmia only after feeding, and their blood-sugar may return to the normal level between meals and during the night. In such patients a sample of blood taken before breakfast will give a normal reading. When the case is more severe, the phase of hyperglycæmia persists longer after each meal and may not pass off completely during the night. The fasting blood-sugar level is therefore high, and glycosuria is present during the whole 24 hours. Such a patient starts his day with a handicap; the blood-sugar, which already stands above the renal threshold, is further raised by each meal, and does not have time to subside far before the next food is taken. It will be seen, then, that the morning blood-sugar value represents the lowest point in the daily cycle in such cases, and when the patient is on a standard diet, the height of the fasting sugar level gives a rough guide to the severity of the case *at the moment.*

Effect of Diet on Fasting Blood-sugar.

The character of the diet that the patient is taking is also a factor in determining the height of his fasting blood-sugar. When he passes from a more meagre to a larger diet, the level of the fasting blood-sugar gradually rises from day to day until a new equilibrium is reached. The full effect may not be evident for some days after the food increase has been made. In the same way reduction of the food intake lowers the fasting sugar levels, a principle that has been made use of in the well-known Allen system. Again, the new level only becomes definitely established after a certain interval. Some patients become sugar-free on slight restriction of diet, others must be deprived of food for two or three days before the blood-sugar falls below the renal threshold level. From this it follows that the state of the blood-sugar and the quantity of sugar lost by the kidney only correspond to the food intake when the patient has been on a constant diet for several days. This fact serves to explain the frequent failure to find a relationship between the food intake and the degree of glycosuria.

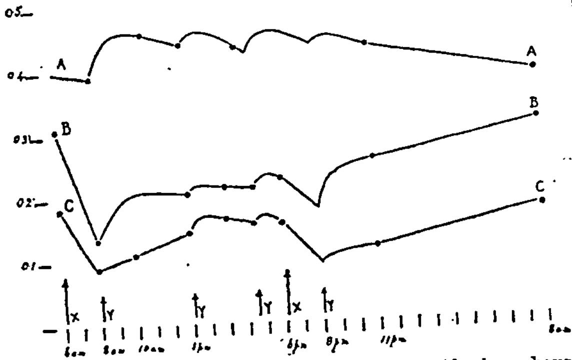
The slow change to a new level is doubtless due to liberation of stored carbohydrate.

The following figures, obtained from a moderately severe case of diabetes, give an idea of the fluctuation in blood-sugar values throughout the day:—

Observation	A	B	C	D	E	F
Hours	0	3	5	8	15	24
Sugar per cent. ..	0·39	0·50	0·44	0·43	0·43	0·38

A is the fasting blood-sugar reading taken at 8 A.M.; B was taken three hours after breakfast and should represent the maximum rise of the post-prandial curve. C and D were taken immediately before dinner and tea respectively. E was taken four hours after supper, and F is the fasting level next morning. The rises after dinner, tea, and supper were not observed but have been guessed at. (See Curve A, Fig. 1.)

FIG. 1.—*To show Changes in Blood-sugar Levels during 26 Hours.*



Ordinates show percentage of blood-sugar, Abscissæ hours. Insulin given to Cases B and C at 6 A.M. and 6 P.M. Case A received no insulin. Meals taken at points Y. Actual observations indicated by dots.

High blood-sugars of this sort lead to considerable waste of carbohydrate by glycosuria, and are also known to aggravate the pancreatic damage. It is therefore desirable to employ insulin in such a manner as to maintain the blood-sugar about the normal level at all times. How best to do this has not been decided.

Effect of a Single Dose of Insulin in a Diabetic Subject.

Insulin given subcutaneously to a fasting patient causes a somewhat slow fall in the blood-sugar during the first half hour. This phase is followed by a much more rapid decline for the next hour or hour and a half, but after the second hour the rate of fall again slows and only a slight further diminution in concentration takes place, although the effect persists for a long time. The minimum point is reached somewhere between the third and the sixth hours, and thereafter the blood-sugar values increase once more. A return to the original fasting level would take place were not the diminishing effect of several hours of starvation superadded. The whole reaction caused by 10 units of insulin lasts more than eight hours, and in many cases the effects are still noticeable 12 to 16 hours after injection.

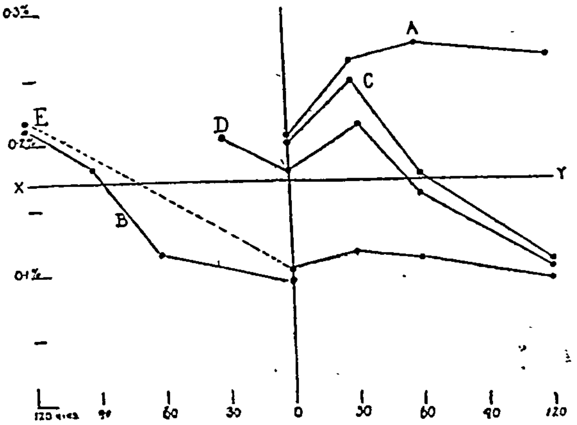
The absorption and the utilisation of insulin is an example of "consecutive reactions" (as has been shown for adrenalin).[1] The rate of removal of the insulin from the site of injection is most rapid at first, when the greatest amount of the drug is present locally, and diminishes later. The amount of the substance in the blood will rise from zero to a maximum concentration, and during this period an increasing effect (blood-sugar fall) will take place. The slow preliminary decline in the blood-sugar values means that a certain time is required for the greater part of the insulin to come into action. Attention should be given to this point in determining the interval between the injection of the drug and the giving of the food it is designed to "cover." Although the quantity of insulin administered may theoretically account for the amount of carbohydrate taken, the rate of absorption of the food might outstrip that of the drug and so upset the calculation. Clinical experience has shown that other factors must be taken into account.

Effect of Varying the Interval between the Administration of Insulin and the Taking of Food.

Little attention seems hitherto to have been given to this question, which appears to be of some importance. When a diabetic takes carbohydrate food his blood-sugar almost at once begins to increase, and rises rapidly to a considerable height. We have seen, however, that the full effect of insulin is not obtained until some half-hour or more after the injection has been given. It will therefore appear that a considerable rise of blood-sugar may take place before sufficient insulin is available to arrest the increase. During this interval glycosuria may occur even when the fasting sugar level has been normal. When the morning blood-sugar is high, as so frequently is the case in these subjects during the early stages of treatment, this loss of sugar in the urine may be of great importance. Even when the amount of carbohydrate and the quantity of insulin were so perfectly matched as to neutralise each other and the reaction commenced from a high fasting level, the subsequent blood-sugar value would still remain above the renal threshold throughout the whole absorption period, and much glucose would be lost. The use of larger doses of insulin might overcome these difficulties by hastening absorption of the drug, but this would add greatly to the expense of treatment.

Observations have been made on the blood-sugar changes and on the urine in patients taking a standard breakfast with a uniform dose of insulin *at different intervals* before the meal. The results are shown in Fig. 2. The breakfast when taken without insulin causes the typical excessive rise in blood-sugar (Curve A). If insulin is given and food is taken immediately afterwards the blood-sugar rises for a time, then falls again fairly abruptly, much earlier

FIG 2.—*To show Effect of Varying the Interval between Injection of Insulin and the Meal Following.*



A standard breakfast was given at the point 0; the figures on the abscissæ indicate minutes before and after commencing the meal.

Curve A, blood-sugar changes when no insulin was given. B, Effect of 10 units of insulin on the fasting blood-sugar. C, Breakfast and insulin taken at same time. D, Insulin given half hour before food. E, Insulin two hours before breakfast. X–Y, Normal level of renal threshold.

---

[1] Lyon, D. M.: The Absorption of Adrenalin, Jour. Exp. Med., xxxviii., 655.

than it would if no insulin were given (Curve C). The fall often continues to a point well below the initial level, the actual degree of reduction depending on the original height of the blood-sugar, the amount of carbohydrate in the meal, and the dose of insulin employed. If an interval of half an hour is allowed the blood-sugar during that period diminishes slightly before the food is taken; a small temporary rise then takes place, to be followed by a greater and more persistent fall (Curve D). The effect of the carbohydrate intake on the blood-sugar is now less than in the former case, but the level may still rise above the renal threshold for a short time.

If a comparatively large dose of insulin is given immediately before a meal, or even half an hour before it, it is possible for glycosuria to occur during the temporary phase of raised blood-sugar, and for symptoms of hypoglycæmia to appear a short time afterwards during the subsequent fall of the blood-sugar. This occurrence of glycosuria in a patient who has regular attacks of hypoglycæmia is rather puzzling at first sight, but a thorough understanding of the blood-sugar changes readily explains it, and the matter can be easily adjusted by balancing the diet and the dose of insulin. When there is a space of two hours between food and insulin conditions are different. This interval is sufficient to permit the insulin to reduce the blood-sugar to within normal limits before the meal is given. The same quantity of food as was formerly taken now produces only a very slight and short-lived rise which does not reach the renal threshold, and the whole reaction indeed closely resembles that which would be produced in a healthy individual (Curve E). No sugar escapes and all the food is made use of.

For the past six months it has been our practice to employ an interval of about two hours between each dose of insulin and the meal which follows. By this plan glycosuria is avoided and the patient is able to make the fullest use of the insulin given. It was thought that although the two-hour interval was the most satisfactory to employ in the morning before breakfast when the fasting blood-sugar required to be brought down to the normal level, a shorter period between dose and meal might be sufficient throughout the day. When the point was investigated, however, it was found that shorter intervals at these times were less satisfactory than the two-hour period. If only half an hour was allowed the dose of insulin had to be increased to produce the same effect. For these reasons it is claimed that the maximum value of the drug is obtained—that is, the largest quantity of food can be "covered" by a definite quantity of insulin—if a period of about two hours elapses before food is taken. This becomes a very important consideration in severe cases of the disease when the amount of the drug available has to be limited because of the expense. A word of caution, however, is necessary at this point.

It has occasionally been found in very severe cases of diabetes of long-standing that on commencing treatment the first doses of insulin given two hours before food are followed by rather severe symptoms of hypoglycæmia, but that a few days later, under apparently the same conditions, no attack occurs. In explanation of this it is suggested that the effect of the insulin does not depend on the height of the blood-sugar alone, but also to some extent on the glycogen content of the tissues. The view has been taken that insulin creates in the tissues a vacuum for glucose. In these severe cases of long standing the tissues contain very little or no glycogen, and under insulin they are able to take in rapidly a very large proportion of the sugar circulating in the blood so that hypoglycæmia is easily induced within two hours. A few days later, when the glycogen content of the tissues has improved, the transference of glucose into them under the same dose of insulin is much less rapid and no symptoms occur in the two-hour period. It would therefore be desirable in *emaciated subjects*, when commencing the use of insulin, to allow an interval of only half an hour between the dose and the meal following for the first three days and thereafter to lengthen the interval to two hours as recommended above. As a matter of fact, cases of this type when first applying for treatment commonly show clinical evidence of acidosis, and attention is directed to treatment of this condition by pushing the carbohydrate intake and neglecting for the time the degree of glycosuria.

How Should the Daily Supply of Insulin be Distributed?

The object to be aimed at in employing insulin is to keep the blood-sugar within normal limits, not only during the digesting periods, but throughout the *whole 24 hours*. How can this be best accomplished?

The total quantity of insulin available may be given as one dose or may be broken up into several equal or unequal fractions to be taken over the day. The suitability of any one method depends to a great extent on the amount of the drug to be employed. Where the total quantity is small (5 or 10 units) it may be given as a single dose, but this method is unsuitable for injections of over 20 units. On the other hand, there are obvious objections to giving a large number of small doses in the day, although this plan would probably more closely follow the natural supply. It is usually found most convenient to divide the insulin into two or three portions. Large doses are much more liable to give rise to hypoglycæmia than smaller ones, so that even when a large morning dose of insulin is followed by a breakfast rich in carbohydrate an attack may be experienced before dinner-time. When all the insulin is given at one time the distribution of the food is less satisfactory, for the later meals in the day must be rather poor in carbohydrate. It is probable, too, that the effect of the single large dose of insulin on the blood-sugar will have worn off 24 hours after the injection. Equal fractions of the total daily supply are usually employed at each injection, but sometimes it seemed preferable to give a slightly larger dose in the morning before breakfast.

The action of the insulin on the blood-sugar can be followed in two ways, (*a*) by making frequent estimations of the blood-sugar, (*b*) by examining each quantity of urine passed. The former method is doubtless more accurate, but is distasteful to the patient and can only be carried out in well-equipped hospitals. Blood-sugar examinations are now no longer done as a routine for the purpose of controlling the patient's food intake. The second plan has a much wider application, and may even be undertaken by the patient himself. It consists in examining two-hourly specimens of urine from 6 A.M. to 10 P.M. and a collected sample for the hours of sleep. This method readily shows whether each meal is adequately covered, or whether it is too rich in carbohydrate, and correction of the food distribution then becomes an easy matter. Such urine examinations are of especial service when a patient who is taking insulin passes only a very small quantity of sugar in the twenty-four hours. Apart from those glycosurias due to toxæmia or to nerve hypertonus, traces of sugar in a sample of mixed urine for the whole day are either caused by the carbohydrate at one or other meal being in excess, or by the effect of the insulin wearing off during the night. Frequent sampling will show at once where the leak occurs.

When two or three doses of insulin are given during the day-time within a space of about eight hours (say from 8 A.M. to 4 P.M.) the influence of the last dose has disappeared long before morning, so that the blood-sugar values creep up during the night, and glycosuria occurs before breakfast. There seems to be a constant tendency for the blood-sugar in the diabetic to return to a high level after it has been lowered by insulin and when presumably all the "extra" mobilised sugar has been stored away. From this it might be inferred that the organism, lacking the normal quantity of insulin, is best able to make use of the glucose when it stands at this high level in

the blood. It may be that the greater concentration, or the greater head of pressure of the sugar, facilitates the transference from the blood-stream into the tissues—a mass action effect. When insulin is supplied, the sugar can be satisfactorily dealt with at a much lower pressure.

Early morning glycosuria proved very troublesome in certain cases until steps were taken to control the blood-sugar during the night as well as in the daytime. This was accomplished by separating the first and the last doses of insulin as widely as possible, allowing not more than 12 hours between the evening dose and the morning one. If the carbohydrate is fairly divided between the "protected" meals there is no danger of an attack of hypoglycæmia during sleep, since the after-supper increase of blood-sugar fills up the lowest part of the evening insulin curve. The presence of a third dose during the day does not affect the position of the other two doses. Failure to control the blood-sugar during the night leads to a high fasting blood-sugar in the morning, so that the patient begins his day at a disadvantage.

Frequent blood-sugar examinations in a series of insulin cases have helped to explain what happens. The following points were chosen for sampling: (A) Fasting level before insulin ; (B) minimum value two hours after insulin and immediately before breakfast ; (C) two hours after breakfast—to catch the height of the post-prandial curve ; (D) level just before dinner ; (E) maximum after dinner ; (F) minimum before tea ; (G) level before evening insulin ; (H) value at 11 P.M. ; (I) fasting level next morning. Meals were given at 8 A.M., 1 P.M., 4.30 P.M., and 8 P.M., the carbohydrate being principally in the breakfast and the supper, and insulin was injected at 6 A.M. and at 6 P.M. The results are shown in the following table (see also curves B and C in Fig. 1)

Table Showing Results of Blood-sugar Examinations in Insulin Cases.

—	A (*a*)	B (*b*)	C	D (c)	E	F (*d*)	G (*e*) (*f*)	H	I

(*a*) Insulin, 6 A.M.
(*b*) Breakfast, 8 A.M.
(*c*) Dinner, 1.15 P.M.
(*d*) Tea, 4.30 P.M.
(*e*) Insulin, 6 P.M.
(*f*) Supper, 8 P.M.

In all cases the highest readings in the 24 hours are the morning fasting values, and when the diet is constant these figures tally fairly closely from day to day. Cases 1, 2, 3, and 4 were examined early in their course of treatment, and showed some sugar in the morning urine specimens. In the case of No. 4 the carbohydrate was arranged for three doses of insulin, but by an oversight the mid-day injection was omitted. This accounts for the very high figures in the afternoon, but the evening dose corrected the hyperglycæmia and the patient started the night with a very low reading.

A valid objection to the control of diet by urine examination alone is that the absence of glycosuria only indicates that the blood-sugar is being kept *below the patient's renal threshold*, and this level in diabetics is often in the neighbourhood of 0·20 per cent. or even 0·25 per cent. Allen's experiments in depancreatised dogs showed that continued hyperglycæmia caused further degeneration of the damaged islets of Langerhans, and clinical experience has amply confirmed this. Patients with persistent hyperglycæmia and glycosuria continue to go downhill, but in such cases the blood-sugar remains above the renal threshold. It is possible, however, that in long-standing diabetes the pancreas and other tissues, as well as the kidneys, have become acclimatised to work best when the blood-sugar level is slightly higher than normal, and that this slightly greater concentration does not lead to the same bad results in them. It may, of course, be simply a matter of degree. Certainly those patients whose diets are controlled by urine examinations alone show marked improvement as treatment proceeds. It has seldom been necessary to give moderately severe cases more than 25 to 30 units of insulin a day to keep them sugar free, to allow them to reach a satisfactory maintenance diet, and to enable them to put on considerable weight. Further, after the same diet has been continued for a time it is usually found that the fasting blood-sugar levels fall still lower and often become normal, while at the same time the dose of insulin required may be reduced to 15 or 10 units. Some fortunate individuals have been able to dispense with the insulin altogether before they left hospital. It would seem probable, therefore, that damage to the pancreas does not follow if the blood-sugar concentration is kept below the level of the renal threshold.

Significance of Fasting Blood-sugar Values.

It was pointed out above that alterations in the level of the fasting blood-sugar from day to day tend to lag behind the changes in diet which produce them. This is seen in two ways. An unexpected return of glycosuria may occur when a patient has been for some days on a fixed diet with a constant amount of insulin. The balance of food intake and insulin dosage appears to be satisfactory and no sugar is lost for two or three days. Then without alteration of either food or insulin the 24 hours specimen of urine will one day give a faint cloud with Fehling's solution. Next day it gives an olive-green colour when tested, and the day after a definite orange. These slighter changes in the urine-Fehling mixture are of considerable importance and are looked upon as the earliest sign that a return of glycosuria is threatened. Certainly, if no reduction of the diet is made on discovering such changes, definite sugar appears within 24 or 48 hours. This gradual return of sugar in the urine has been taken to mean that the amount of food eaten was a little too high for the quantity of insulin given, and has thus led to a slow rise in the fasting blood-sugar level from day to day until the renal threshold was passed and glycosuria became evident. Such a reappearance of a positive reaction with Fehling's solution is most likely to occur when the patient has left hospital and is trying to take as high a maintenance diet as possible in order to allow him to work. The return of sugar in the urine is always a disappointment to the patient, and should be avoided if possible. It is a good plan to insist on such a patient taking a lower diet once a week. Instead of his usual 2500 or 2800 calorie diet he drops for one day to 1200 or 1500 calories, at the same time continuing his insulin as usual. If hypoglycæmia threatens on such a low day the reduction in food is not necessary and the low day may be discontinued. The introduction of a half-ration day definitely reduces the fasting blood-sugar level and prevents it from ever reaching or surpassing the renal threshold.

The lag effect is also seen in the opposite direction. In certain cases, as treatment advances, the patient begins to find that he experiences slight symptoms of hypoglycæmia—hunger, slight flushing, perspiration, or shakiness—about 1¼ or 1¾ hours after the insulin has been injected. These symptoms may also appear for the first time after the patient has apparently been stabilised on a definite food-insulin balance for several days without having attacks. In this case the insulin is more than sufficient the purpose intended. The appearance of slight signs of hypoglycæmia indicates that the sugar has fallen to about 0·7 per cent. or low probably implies that the original morning level was normal or only slightly elevat patients before leaving hospital are recognise the signs of hypoglycæmia and h

than it would if no insulin were given (Curve C). The fall often continues to a point well below the initial level, the actual degree of reduction depending on the original height of the blood-sugar, the amount of carbohydrate in the meal, and the dose of insulin employed. If an interval of half an hour is allowed the blood-sugar during that period diminishes slightly before the food is taken; a small temporary rise then takes place, to be followed by a greater and more persistent fall (Curve D). The effect of the carbohydrate intake on the blood-sugar is now less than in the former case, but the level may still rise above the renal threshold for a short time.

If a comparatively large dose of insulin is given immediately before a meal, or even half an hour before it, it is possible for glycosuria to occur during the temporary phase of raised blood-sugar, and for symptoms of hypoglycæmia to appear a short time afterwards during the subsequent fall of the blood-sugar. This occurrence of glycosuria in a patient who has regular attacks of hypoglycæmia is rather puzzling at first sight, but a thorough understanding of the blood-sugar changes readily explains it, and the matter can be easily adjusted by balancing the diet and the dose of insulin. When there is a space of two hours between food and insulin conditions are different. This interval is sufficient to permit the insulin to reduce the blood-sugar to within normal limits before the meal is given. The same quantity of food as was formerly taken now produces only a very slight and short-lived rise which does not reach the renal threshold, and the whole reaction indeed closely resembles that which would be produced in a healthy individual (Curve E). No sugar escapes and all the food is made use of.

For the past six months it has been our practice to employ an interval of about two hours between each dose of insulin and the meal which follows. By this plan glycosuria is avoided and the patient is able to make the fullest use of the insulin given. It was thought that although the two-hour interval was the most satisfactory to employ in the morning before breakfast when the fasting blood-sugar required to be brought down to the normal level, a shorter period between dose and meal might be sufficient throughout the day. When the point was investigated, however, it was found that shorter intervals at these times were less satisfactory than the two-hour period. If only half an hour was allowed the dose of insulin had to be increased to produce the same effect. For these reasons it is claimed that the maximum value of the drug is obtained—that is, the largest quantity of food can be "covered" by a definite quantity of insulin—if a period of about two hours elapses before food is taken. This becomes a very important consideration in severe cases of the disease when the amount of the drug available has to be limited because of the expense. A word of caution, however, is necessary at this point.

It has occasionally been found in very severe cases of diabetes of long-standing that on commencing treatment the first doses of insulin given two hours before food are followed by rather severe symptoms of hypoglycæmia, but that a few days later, under apparently the same conditions, no attack occurs. In explanation of this it is suggested that the effect of the insulin does not depend on the height of the blood-sugar alone, but also to some extent on the glycogen content of the tissues. The view has been taken that insulin creates in the tissues a vacuum for glucose. In these severe cases of long standing the tissues contain very little or no glycogen, and under insulin they are able to take in rapidly a very large proportion of the sugar circulating in the blood so that hypoglycæmia is easily induced within two hours. A few days later, when the glycogen content of the tissues has improved, the transference of glucose into them under the same dose of insulin is much less rapid and no symptoms occur in the two-hour period. It would therefore be desirable in *emaciated subjects*, when commencing the use of insulin, to allow an interval of only half an hour between the dose and the meal following for the first three days and thereafter to lengthen the interval to two hours as recommended above. As a matter of fact, cases of this type when first applying for treatment commonly show clinical evidence of acidosis, and attention is directed to treatment of this condition by pushing the carbohydrate intake and neglecting for the time the degree of glycosuria.

How Should the Daily Supply of Insulin be Distributed?

The object to be aimed at in employing insulin is to keep the blood-sugar within normal limits, not only during the digesting periods, but throughout the *whole 24 hours*. How can this be best accomplished?

The total quantity of insulin available may be given as one dose or may be broken up into several equal or unequal fractions to be taken over the day. The suitability of any one method depends to a great extent on the amount of the drug to be employed. Where the total quantity is small (5 or 10 units) it may be given as a single dose, but this method is unsuitable for injections of over 20 units. On the other hand, there are obvious objections to giving a large number of small doses in the day, although this plan would probably more closely follow the natural supply. It is usually found most convenient to divide the insulin into two or three portions. Large doses are much more liable to give rise to hypoglycæmia than smaller ones, so that even when a large morning dose of insulin is followed by a breakfast rich in carbohydrate an attack may be experienced before dinner-time. When all the insulin is given at one time the distribution of the food is less satisfactory, for the later meals in the day must be rather poor in carbohydrate. It is probable, too, that the effect of the single large dose of insulin on the blood-sugar will have worn off 24 hours after the injection. Equal fractions of the total daily supply are usually employed at each injection, but sometimes it seemed preferable to give a slightly larger dose in the morning before breakfast.

The action of the insulin on the blood-sugar can be followed in two ways, (*a*) by making frequent estimations of the blood-sugar, (*b*) by examining each quantity of urine passed. The former method is doubtless more accurate, but is distasteful to the patient and can only be carried out in well-equipped hospitals. Blood-sugar examinations are now no longer done as a routine for the purpose of controlling the patient's food intake. The second plan has a much wider application, and may even be undertaken by the patient himself. It consists in examining two-hourly specimens of urine from 6 A.M. to 10 P.M. and a collected sample for the hours of sleep. This method readily shows whether each meal is adequately covered, or whether it is too rich in carbohydrate, and correction of the food distribution then becomes an easy matter. Such urine examinations are of especial service when a patient who is taking insulin passes only a very small quantity of sugar in the twenty-four hours. Apart from those glycosurias due to toxæmia or to nerve hypertonus, traces of sugar in a sample of mixed urine for the whole day are either caused by the carbohydrate at one or other meal being in excess, or by the effect of the insulin wearing off during the night. Frequent sampling will show at once where the leak occurs.

When two or three doses of insulin are given during the day-time within a space of about eight hours (say from 8 A.M. to 4 P.M.) the influence of the last dose has disappeared long before morning, so that the blood-sugar values creep up during the night, and glycosuria occurs before breakfast. There seems to be a constant tendency for the blood-sugar in the diabetic to return to a high level after it has been lowered by insulin and when presumably all the "extra" mobilised sugar has been stored away. From this it might be inferred that the organism, lacking the normal quantity of insulin, is best able to make use of the glucose when it stands at this high level in

he blood. It may be that the greater concentration, or the greater head of pressure of the sugar, facilitates he transference from the blood-stream into the issues—a mass action effect. When insulin is supplied, he sugar can be satisfactorily dealt with at a much ower pressure.

Early morning glycosuria proved very troublesome n certain cases until steps were taken to control the blood-sugar during the night as well as in the daytime. This was accomplished by separating the first and the last doses of insulin as widely as possible, allowing not more than 12 hours between the evening dose and the morning one. If the carbohydrate is fairly divided between the "protected" meals there is no danger of an attack of hypoglycæmia during sleep, since the after-supper increase of blood-sugar fills up the lowest part of the evening insulin curve. The presence of a third dose during the day does not affect the position of the other two doses. Failure to control the blood-sugar during the night leads to a high fasting blood-sugar in the morning, so that the patient begins his day at a disadvantage.

Frequent blood-sugar examinations in a series of insulin cases have helped to explain what happens. The following points were chosen for sampling: (A) Fasting level before insulin; (B) minimum value two hours after insulin and immediately before breakfast; (C) two hours after breakfast—to catch the height of the post-prandial curve; (D) level just before dinner; (E) maximum after dinner; (F) minimum before tea; (G) level before evening insulin; (H) value at 11 P.M.; (I) fasting level next morning. Meals were given at 8 A.M., 1 P.M., 4.30 P.M., and 8 P.M., the carbohydrate being principally in the breakfast and the supper, and insulin was injected at 6 A.M. and at 6 P.M. The results are shown in the following table (see also curves B and C in Fig. 1)

In all cases the highest readings in the 24 hours are the morning fasting values, and when the diet is constant these figures tally fairly closely from day to day. Cases 1, 2, 3, and 4 were examined early in their course of treatment, and showed some sugar in the morning urine specimens. In the case of No. 4 the carbohydrate was arranged for three doses of insulin, but by an oversight the mid-day injection was omitted. This accounts for the very high figures in the afternoon, but the evening dose corrected the hyperglycæmia and the patient started the night with a very low reading.

A valid objection to the control of diet by urine examination alone is that the absence of glycosuria only indicates that the blood-sugar is being kept *below the patient's renal threshold*, and this level in diabetics is often in the neighbourhood of 0·20 per cent. or even 0·25 per cent. Allen's experiments in depancreatised dogs showed that continued hyperglycæmia caused further degeneration of the damaged islets of Langerhans, and clinical experience has amply confirmed this. Patients with persistent hyperglycæmia and glycosuria continue to go downhill, but in such cases the blood-sugar remains above the renal threshold. It is possible, however, that in long-standing diabetes the pancreas and other tissues, as well as the kidneys, have become acclimatised to work best when the blood-sugar level is slightly higher than normal, and that this slightly greater concentration does not lead to the same bad results in them. It may, of course, be simply a matter of degree. Certainly those patients whose diets are controlled by urine examinations alone show marked improvement as treatment proceeds. It has seldom been necessary to give moderately severe cases more than 25 to 30 units of insulin a day to keep them sugar free, to allow them to reach a satisfactory maintenance diet, and to enable them to put on considerable weight. Further, after the same diet has been continued for a time it is usually found that the fasting blood-sugar levels fall still lower and often become normal, while at the same time the dose of insulin required may be reduced to 15 or 10 units. Some fortunate individuals have been able to dispense with the insulin altogether before they left hospital. It would seem probable, therefore, that damage to the pancreas does not follow if the blood-sugar concentration is kept below the level of the renal threshold.

Significance of Fasting Blood-sugar Values.

It was pointed out above that alterations in the level of the fasting blood-sugar from day to day tend to lag behind the changes in diet which produce them. This is seen in two ways. An unexpected return of glycosuria may occur when a patient has been for some days on a fixed diet with a constant amount of insulin. The balance of food intake and insulin dosage appears to be satisfactory and no sugar is lost for two or three days. Then without alteration of either food or insulin the 24 hours specimen of urine will one day give a faint cloud with Fehling's solution. Next day it gives an olive-green colour when tested, and the day after a definite orange. These slighter changes in the urine-Fehling mixture are of considerable importance and are looked upon as the earliest sign that a return of glycosuria is threatened. Certainly, if no reduction of the diet is made on discovering such changes, definite sugar appears within 24 or 48 hours. This gradual return of sugar in the urine has been taken to mean that the amount of food eaten was a little too high for the quantity of insulin given, and has thus led to a slow rise in the fasting blood-sugar level from day to day until the renal threshold was passed and glycosuria became evident. Such a reappearance of a positive reaction with Fehling's solution is most likely to occur when the patient has left hospital and is trying to take as high a maintenance diet as possible in order to allow him to work. The return of sugar in the urine is always a disappointment to the patient, and should be avoided if possible. It is a good plan to insist on such a patient taking a lower diet once a week. Instead of his usual 2500 or 2800 calorie diet he drops for one day to 1200 or 1500 calories, at the same time continuing his insulin as usual. If hypoglycæmia threatens on such a low day the reduction in food is not necessary and the low day may be discontinued. The introduction of a half-ration day definitely reduces the fasting blood-sugar level and prevents it from ever reaching or surpassing the renal threshold.

The lag effect is also seen in the opposite direction. In certain cases, as treatment advances, the patient begins to find that he experiences slight symptoms of hypoglycæmia—hunger, slight flushing, perspiration, or shakiness—about 1¼ or 1¾ hours after the insulin has been injected. These symptoms may also appear for the first time after the patient has apparently been stabilised on a definite food-insulin balance for several days without having attacks. In this case the insulin is more than sufficient for the purpose intended. The appearance of these slight signs of hypoglycæmia indicates that the blood-sugar has fallen to about 0·7 per cent. or lower, and probably implies that the original morning fasting level was normal or only slightly elevated. All patients before leaving hospital are taught to recognise the signs of hypoglycæmia and how to cut

than it would if no insulin were given (Curve C). The fall often continues to a point well below the initial level, the actual degree of reduction depending on the original height of the blood-sugar, the amount of carbohydrate in the meal, and the dose of insulin employed. If an interval of half an hour is allowed the blood-sugar during that period diminishes slightly before the food is taken; a small temporary rise then takes place, to be followed by a greater and more persistent fall (Curve D). The effect of the carbohydrate intake on the blood-sugar is now less than in the former case, but the level may still rise above the renal threshold for a short time.

If a comparatively large dose of insulin is given immediately before a meal, or even half an hour before it, it is possible for glycosuria to occur during the temporary phase of raised blood-sugar, and for symptoms of hypoglycæmia to appear a short time afterwards during the subsequent fall of the blood-sugar. This occurrence of glycosuria in a patient who has regular attacks of hypoglycæmia is rather puzzling at first sight, but a thorough understanding of the blood-sugar changes readily explains it, and the matter can be easily adjusted by balancing the diet and the dose of insulin. When there is a space of two hours between food and insulin conditions are different. This interval is sufficient to permit the insulin to reduce the blood-sugar to within normal limits before the meal is given. The same quantity of food as was formerly taken now produces only a very slight and short-lived rise which does not reach the renal threshold, and the whole reaction indeed closely resembles that which would be produced in a healthy individual (Curve E). No sugar escapes and all the food is made use of.

For the past six months it has been our practice to employ an interval of about two hours between each dose of insulin and the meal which follows. By this plan glycosuria is avoided and the patient is able to make the fullest use of the insulin given. It was thought that although the two-hour interval was the most satisfactory to employ in the morning before breakfast when the fasting blood-sugar required to be brought down to the normal level, a shorter period between dose and meal might be sufficient throughout the day. When the point was investigated, however, it was found that shorter intervals at these times were less satisfactory than the two-hour period. If only half an hour was allowed the dose of insulin had to be increased to produce the same effect. For these reasons it is claimed that the maximum value of the drug is obtained—that is, the largest quantity of food can be "covered" by a definite quantity of insulin—if a period of about two hours elapses before food is taken. This becomes a very important consideration in severe cases of the disease when the amount of the drug available has to be limited because of the expense. A word of caution, however, is necessary at this point.

It has occasionally been found in very severe cases of diabetes of long-standing that on commencing treatment the first doses of insulin given two hours before food are followed by rather severe symptoms of hypoglycæmia, but that a few days later, under apparently the same conditions, no attack occurs. In explanation of this it is suggested that the effect of the insulin does not depend on the height of the blood-sugar alone, but also to some extent on the glycogen content of the tissues. The view has been taken that insulin creates in the tissues a vacuum for glucose. In these severe cases of long standing the tissues contain very little or no glycogen, and under insulin they are able to take in rapidly a very large proportion of the sugar circulating in the blood so that hypoglycæmia is easily induced within two hours. A few days later, when the glycogen content of the tissues has improved, the transference of glucose into them under the same dose of insulin is much less rapid and no symptoms occur in the two-hour period. It would therefore be desirable in *emaciated subjects*, when commencing the use of insulin, to allow an interval of only half an hour between the dose and the meal following for the first three days and thereafter to lengthen the interval to two hours as recommended above. As a matter of fact, cases of this type when first applying for treatment commonly show clinical evidence of acidosis, and attention is directed to treatment of this condition by pushing the carbohydrate intake and neglecting for the time the degree of glycosuria.

How Should the Daily Supply of Insulin be Distributed?

The object to be aimed at in employing insulin is to keep the blood-sugar within normal limits, not only during the digesting periods, but throughout the *whole 24 hours*. How can this be best accomplished?

The total quantity of insulin available may be given as one dose or may be broken up into several equal or unequal fractions to be taken over the day. The suitability of any one method depends to a great extent on the amount of the drug to be employed. Where the total quantity is small (5 or 10 units) it may be given as a single dose, but this method is unsuitable for injections of over 20 units. On the other hand, there are obvious objections to giving a large number of small doses in the day, although this plan would probably more closely follow the natural supply. It is usually found most convenient to divide the insulin into two or three portions. Large doses are much more liable to give rise to hypoglycæmia than smaller ones, so that even when a large morning dose of insulin is followed by a breakfast rich in carbohydrate an attack may be experienced before dinner-time. When all the insulin is given at one time the distribution of the food is less satisfactory, for the later meals in the day must be rather poor in carbohydrate. It is probable, too, that the effect of the single large dose of insulin on the blood-sugar will have worn off 24 hours after the injection. Equal fractions of the total daily supply are usually employed at each injection, but sometimes it seemed preferable to give a slightly larger dose in the morning before breakfast.

The action of the insulin on the blood-sugar can be followed in two ways, (*a*) by making frequent estimations of the blood-sugar, (*b*) by examining each quantity of urine passed. The former method is doubtless more accurate, but is distasteful to the patient and can only be carried out in well-equipped hospitals. Blood-sugar examinations are now no longer done as a routine for the purpose of controlling the patient's food intake. The second plan has a much wider application, and may even be undertaken by the patient himself. It consists in examining two-hourly specimens of urine from 6 A.M. to 10 P.M. and a collected sample for the hours of sleep. This method readily shows whether each meal is adequately covered, or whether it is too rich in carbohydrate, and correction of the food distribution then becomes an easy matter. Such urine examinations are of especial service when a patient who is taking insulin passes only a very small quantity of sugar in the twenty-four hours. Apart from those glycosurias due to toxæmia or to nerve hypertonus, traces of sugar in a sample of mixed urine for the whole day are either caused by the carbohydrate at one or other meal being in excess, or by the effect of the insulin wearing off during the night. Frequent sampling will show at once where the leak occurs.

When two or three doses of insulin are given during the day-time within a space of about eight hours (say from 8 A.M. to 4 P.M.) the influence of the last dose has disappeared long before morning, so that the blood-sugar values creep up during the night, and glycosuria occurs before breakfast. There seems to be a constant tendency for the blood-sugar in the diabetic to return to a high level after it has been lowered by insulin and when presumably all the "extra" mobilised sugar has been stored away. From this it might be inferred that the organism, lacking the normal quantity of insulin, is best able to make use of the glucose when it stands at this high level in

the blood. It may be that the greater concentration, or the greater head of pressure of the sugar, facilitates the transference from the blood-stream into the tissues—a mass action effect. When insulin is supplied, the sugar can be satisfactorily dealt with at a much lower pressure.

Early morning glycosuria proved very troublesome in certain cases until steps were taken to control the blood-sugar during the night as well as in the daytime. This was accomplished by separating the first and the last doses of insulin as widely as possible, allowing not more than 12 hours between the evening dose and the morning one. If the carbohydrate is fairly divided between the "protected" meals there is no danger of an attack of hypoglycæmia during sleep, since the after-supper increase of blood-sugar fills up the lowest part of the evening insulin curve. The presence of a third dose during the day does not affect the position of the other two doses. Failure to control the blood-sugar during the night leads to a high fasting blood-sugar in the morning, so that the patient begins his day at a disadvantage.

Frequent blood-sugar examinations in a series of insulin cases have helped to explain what happens. The following points were chosen for sampling: (A) Fasting level before insulin; (B) minimum value two hours after insulin and immediately before breakfast; (C) two hours after breakfast—to catch the height of the post-prandial curve; (D) level just before dinner; (E) maximum after dinner; (F) minimum before tea; (G) level before evening insulin; (H) value at 11 P.M.; (I) fasting level next morning. Meals were given at 8 A.M., 1 P.M., 4.30 P.M., and 8 P.M., the carbohydrate being principally in the breakfast and the supper, and insulin was injected at 6 A.M. and at 6 P.M. The results are shown in the following table (see also curves B and C in Fig. 1)

Table Showing Results of Blood-sugar Examinations in Insulin Cases.

	A (*a*)	B (*b*)	C	D (*c*)	E	F (*d*)	G (*e*) (*f*)	H	I
	6 A.M.	8 A.M.	10 A.M.	1 P.M.	3 P.M.	4.30 P.M.	6 P.M.	11 P.M.	8 A.M.
1	0·31	0·13	—	0·20	0·21	—	0·23	0·25	0·30
2	0·29	0·19	—	0·12	0·22	—	0·22	0·22	0·29
3	0·31	0·16	0·12	0·08	—	—	0·22	0·22	0·31

(*a*) Insulin, 6 A.M.
(*b*) Breakfast, 8 A.M.
(*c*) Dinner, 1.15 P.M.
(*d*) Tea, 4.30 P.M.
(*e*) Insulin, 6 P.M.
(*f*) Supper, 8 P.M.

In all cases the highest readings in the 24 hours are the morning fasting values, and when the diet is constant these figures tally fairly closely from day to day. Cases 1, 2, 3, and 4 were examined early in their course of treatment, and showed some sugar in the morning urine specimens. In the case of No. 4 the carbohydrate was arranged for three doses of insulin, but by an oversight the mid-day injection was omitted. This accounts for the very high figures in the afternoon, but the evening dose corrected the hyperglycæmia and the patient started the night with a very low reading.

A valid objection to the control of diet by urine examination alone is that the absence of glycosuria only indicates that the blood-sugar is being kept *below the patient's renal threshold*, and this level in diabetics is often in the neighbourhood of 0·20 per cent. or even 0·25 per cent. Allen's experiments in depancreatised dogs showed that continued hyperglycæmia caused further degeneration of the damaged islets of Langerhans, and clinical experience has amply confirmed this. Patients with persistent hyperglycæmia and glycosuria continue to go downhill, but in such cases the blood-sugar remains above the renal threshold. It is possible, however, that in long-standing diabetes the pancreas and other tissues, as well as the kidneys, have become acclimatised to work best when the blood-sugar level is slightly higher than normal, and that this slightly greater concentration does not lead to the same bad results in them. It may, of course, be simply a matter of degree. Certainly those patients whose diets are controlled by urine examinations alone show marked improvement as treatment proceeds. It has seldom been necessary to give moderately severe cases more than 25 to 30 units of insulin a day to keep them sugar free, to allow them to reach a satisfactory maintenance diet, and to enable them to put on considerable weight. Further, after the same diet has been continued for a time it is usually found that the fasting blood-sugar levels fall still lower and often become normal, while at the same time the dose of insulin required may be reduced to 15 or 10 units. Some fortunate individuals have been able to dispense with the insulin altogether before they left hospital. It would seem probable, therefore, that damage to the pancreas does not follow if the blood-sugar concentration is kept below the level of the renal threshold.

Significance of Fasting Blood-sugar Values.

It was pointed out above that alterations in the level of the fasting blood-sugar from day to day tend to lag behind the changes in diet which produce them. This is seen in two ways. An unexpected return of glycosuria may occur when a patient has been for some days on a fixed diet with a constant amount of insulin. The balance of food intake and insulin dosage appears to be satisfactory and no sugar is lost for two or three days. Then without alteration of either food or insulin the 24 hours specimen of urine will one day give a faint cloud with Fehling's solution. Next day it gives an olive-green colour when tested, and the day after a definite orange. These slighter changes in the urine-Fehling mixture are of considerable importance and are looked upon as the earliest sign that a return of glycosuria is threatened. Certainly, if no reduction of the diet is made on discovering such changes, definite sugar appears within 24 or 48 hours. This gradual return of sugar in the urine has been taken to mean that the amount of food eaten was a little too high for the quantity of insulin given, and has thus led to a slow rise in the fasting blood-sugar level from day to day until the renal threshold was passed and glycosuria became evident. Such a reappearance of a positive reaction with Fehling's solution is most likely to occur when the patient has left hospital and is trying to take as high a maintenance diet as possible in order to allow him to work. The return of sugar in the urine is always a disappointment to the patient, and should be avoided if possible. It is a good plan to insist on such a patient taking a lower diet once a week. Instead of his usual 2500 or 2800 calorie diet he drops for one day to 1200 or 1500 calories, at the same time continuing his insulin as usual. If hypoglycæmia threatens on such a low day the reduction in food is not necessary and the low day may be discontinued. The introduction of a half-ration day definitely reduces the fasting blood-sugar level and prevents it from ever reaching or surpassing the renal threshold.

The lag effect is also seen in the opposite direction. In certain cases, as treatment advances, the patient begins to find that he experiences slight symptoms of hypoglycæmia—hunger, slight flushing, perspiration, or shakiness—about 1¼ or 1¾ hours after the insulin has been injected. These symptoms may also appear for the first time after the patient has apparently been stabilised on a definite food-insulin balance for several days without having attacks. In this case the insulin is more than sufficient for the purpose intended. The appearance of these slight signs of hypoglycæmia indicates that the blood-sugar has fallen to about 0·7 per cent. or lower, and probably implies that the original morning fasting level was normal or only slightly elevated. All patients before leaving hospital are taught to recognise the signs of hypoglycæmia and how to cut

AN INVESTIGATION INTO CRITERIA FOR ARTIFICIAL PNEUMOTHORAX

SERVICEABLE AS GUIDES TO TREATMENT.

BY R. C. WINGFIELD, M.B. OXF., M.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, BROMPTON HOSPITAL SANATORIUM, FRIMLEY;

AND

G. SELBY WILSON, M.D., M.R.C.P. LOND., D.P.H.,
DEPARTMENT OF PUBLIC HEALTH, MANCHESTER.

DURING the past two years there have been exceptional facilities at Frimley for observing cases of artificial pneumothorax. In this paper we have analysed certain outstanding clinical phenomena occurring in these cases during treatment, and endeavoured to correlate them with the immediate results obtained, in the hope that by this means we might acquire some information that would guide us in the treatment of our cases. We mean by "treatment" in this paper the general conduct of these cases at a sanatorium apart from the actual artificial pneumothorax treatment. Our conclusions have no bearing on the question of the value of artificial pneumothorax treatment, nor on the question of the proper amounts of air to be used in, or the correct spacing of, refills.

The cases have been of all types, and no selection whatever has been made. In the larger number, 60 out of 75, the pneumothorax was induced at Brompton Hospital. These are all Group 2 or Group 3 (L.C.C. classification) cases. The majority have been cases done for choice, presenting the probability of a good result, but some, especially those induced at the Sanatorium, have been "last resort" cases. As this paper does not deal with "choice of case" or "suitability of treatment" or the results of artificial pneumothorax treatment *versus* any other form of treatment, these have all been classed together. The length of time between the induction of artificial pneumothorax and the commencement of exercise has been variable, and has, on the whole, been longer in those cases induced at Brompton Hospital than in those induced at the Sanatorium. The shortest time has been six days and the longest 285 days; the average time has been 106 days.

The cases are all drawn from the working classes, and, in laying down a course of treatment for them, it has to be borne in mind that, with very few exceptions, they have got to earn their own livings, the only alternative being the workhouse infirmary. Further, the length of time that can be devoted to treatment is limited to a certain extent by financial conditions. Although those who are under the care of the L.C.C. are given the most generous allowance of institutional treatment if there is the slightest chance of a favourable result yet there is a limit even to this. Other considerations such as the home finance, also have a great influence in L.C.C. cases, and more so when the patient or his family is bearing the cost of institutional treatment. This point has to be made clear, so that it may be obvious that in different circumstances the line of treatment adopted might be greatly modified.

DEFINITIONS.

For the proper reading of the following tables certain definitions are necessary.

Length of Treatment.—In all our calculations this has been taken from the time the patient started his first walking exercise up to the date of departure.

Classification.—The patients have been classified as to the immediate results of treatment as "much improved," "improved," "in statu quo," "worse," or "dead." As far as possible, this classification has been made absolute and not relative—that is to say, the initial condition of the patient has not been taken into account. Although a patient may have been saved from rapidly impending death by the induction of an artificial pneumothorax, unless he is discharged with practically no symptoms and fit to work he is not classified as "much improved."

"*Much Improved.*"—Practically free from symptoms. Apparently fit to work and earn a living. No pyrexia.

"*Improved.*"—Symptoms much ameliorated. Apparently fit to be up and about and to do light work. No pyrexia.

"*I.S.Q.*"—Symptoms still present. Apparently unfit to earn a living. Pyrexial or non-pyrexial.

"*Worse or Dead.*"—In this paper the I.S.Q., worse, and dead patients have been classified in one group labelled "worse."

Pyrexia.—A recorded mouth temperature during the day of over 99° F.

Relapse.—Any condition, whether accompanied by pyrexia or not, which has necessitated the patient stopping exercise and being put on "rest" for four days or more.

EXERCISE AND LABOUR.

Walking Exercise.—Grades of walking range from half to eight miles a day. To this must be added the exercise taken by the patient during his reaction hours—an amount that cannot be measured, and depending on the common-sense of the individual. In some cases this unmeasured exercise is excessive, and may be a great factor in controlling the apparent response to treatment.

Labour.—Work is done in two shifts of two hours each, but in some cases the second shift is only one and a half hours. It is divided roughly into five grades, but the actual work of each patient is considered separately, and two patients in the same grade may be doing very different amounts of work if measured in foot pounds. To this, again, has to be added exercise taken during recreation, with the same remarks as to its importance.

Grade 1: Carrying small baskets holding about 7 lb.

Grade 2: Carrying baskets holding about 14 lb. Light hoeing and weeding.

Grade 3: Carting, with three mates, using a light hand-cart. Hoeing and light digging with a small fork. Rolling, three men to a light roller.

Grade 4: Carting, with two mates, using same cart. Digging, using a medium fork. Cross-cut sawing. Mowing and rolling.

Grade 5: Digging and trenching, using full-size tools. Cross-cut sawing. Rolling and mowing.

The precision with which this form of treatment is carried out depends on the individual, but we hope that our numbers are sufficient to balance errors arising from personal inequalities in the performance of the work.

Nature and Incidence of Relapses in Relation to Immediate Results of Treatment.

As our definition shows, we have stretched the meaning of the word "relapse" to cover widely different conditions. It may mean, on the one hand, a definite set-back with exacerbation of the disease, or, on the other hand, a short cessation from exercise deemed necessary because of some slight, or even imaginary, clinical warning. The long relapses are of the first type, the shorter ones mainly of the second type. As might be expected, the probability of relapse varies inversely with the response to treatment, but our figures in Table I. show that the actual length of each relapse is of prognostic significance. This is found to be shortest in the "much-improved" class, and longest in the "worse" class, those in the "improved" class falling between the two. This fact is shown more clearly when viewed from a different standpoint, as is done in Table II. So that one can say that a long relapse denotes a bad prognosis. But, as will appear later, if that relapse is caused by the temporary disturbance of health coincident with the appearance of pleural fluid, although it may be of some length, it is not necessarily of bad prognostic significance.

The stage of exercise at which relapse occurs appears to be of extreme importance. Our findings are set forth in Table III., which shows that if a patient is able to reach a certain stage of walking exercise without relapse, he will probably be discharged as much improved; and even though relapses do occur in the much-improved class during the working period, it is obvious they must be very insignificant, and rest has been ordered more by way of a precautionary measure. If it is allowed, provided that other factors do not contradict it, that the best short an attack, so no harm results from the appearance of slight manifestations. When this stage of treatment is reached and the patient is experiencing slight attacks, several courses are open. The interval between the injection and the meal may be shortened. This avoids the appearance of the symptoms, and at the same time keeps the blood-sugar at a low level. Alternatively, the amount of food taken may be increased daily until the symptoms cease to appear; or thirdly, the diet may be kept constant while the dose of insulin is reduced. All these procedures have been followed as occasions warranted.

It has not yet been definitely decided whether in all cases an endeavour should be made to keep the fasting blood-sugar level as low as possible, or whether as good results are to be obtained by merely avoiding glycosuria. The former plan would seem to be preferable, at least for a time, during the earlier stages of treatment, but of course it requires larger doses of insulin. The question is often decided automatically by the economic situation, when it is necessary to obtain the maximum result with the smallest outlay.

Reliability of Commercial Insulin.

Considering that the only method at present available for the standardisation of insulin is a pharmacological assay of doubtful value, the uniformity of the strength of the insulin supplied is remarkable. It is rather easy to check the quality of a new sample on patients who have been under control for some time. As a rule, a definite dose of a fresh batch of the substance can be relied upon to "cover" as much carbohydrate as the last batch did. From time to time, however, sugar returns in the urine of "pedigreed" patients who have carefully followed out their usual régime. Were such instances isolated, it might be thought that the glycosuria was due to faulty dieting, intercurrent toxæmia, or passing nervous strain (worry, excitement, &c.) These failures, however, usually appear in groups, complaints being received from other wards and from out-patients who are using the same batch of the drug. Sometimes the strength appears to be little more than half the normal worth. Since errors may appear on the side of weakness, it is possible that some batches of insulin issued are over-strength. This fault would not be so readily detected, unless by the sudden occurrence of hypoglycæmia in cases where the fasting blood-sugar was being kept at a very low level. The tendency to occasional variability in the strength of the insulin must be kept in mind when an unexpected reappearance of glycosuria occurs.

THE TREATMENT OF TUBERCULOSIS WITH SODIUM MORRHUATE.

By JOHN HUME, M.D. Edin., D.P.H. St. And.,
MEDICAL OFFICER TO OUT-PATIENTS, ROYAL INFIRMARY, PERTH.

A few years ago sodium morrhuate, a sodium salt of cod-liver oil, was introduced by Sir Leonard Rogers as a remedy for tuberculosis. I have found this remedy of great help in advanced cases, but not so successful as in the early ones, in whom it appears to lead to a complete arrest of the disease. It is easily administered by subcutaneous injection.

I usually begin with 0·5 c.cm., and if the reaction is only very slight, I proceed to a dose of 1 c.cm., administered twice weekly. There does not appear to be any advantage in using a larger dose. Sometimes a slight local reaction around the needle puncture is observed which is apt to occur if a month or so had elapsed since the last injection. It is used in a 3 per cent. solution obtainable in rubber-capped bottles. It is essential to let the bottle stand in warm water for a few minutes before use, when it should be clear and not the least muddy.

Descriptive Cases.

The following is an account of 11 patients treated by this method:—

Case 1.—Mr. J. T., aged 28 years, had been ill for six months previous to seeing me in June, 1919, shortly after he had had slight hæmoptysis. His evening temperature was 101·5° F. There was consolidation of the left apex, night-sweats, and T.B. in sputum. Weight on commencing treatment 9 st. 2 lb. In September, 1919, the night-sweats had ceased. He was feeling stronger, and the T.B. were less numerous in the sputum. His weight was then 9 st. 11 lb. In December, 1919, there was no T.B. in the sputum, no cough, and weight was 10 st. 7 lb.

This patient received 59 injections, using in all 56 c.cm. of sodium morrhuate. In 1920 he went to America and has been working there since then as a traveller.

Case 2.—Mr. A. C., aged 21. In January, 1920, he had consolidation of the right apex, dullness on percussion, and crepitations, night-sweats, and T.B. present in the sputum. Weight was 8 st. 11 lb. At the end of eight months' treatment no T.B. were found in the sputum, night-sweats had gone, and there were no crepitations. There was only slight dullness on percussion. His weight was now 9 st. 10 lb.

Case 3.—Mr. D. T., aged 18, consulted me in March, 1920. He had consolidation of the left base, crepitations, night sweats, cough, T.B. in the sputum. Weight 9 st. 3 lb. After six months' treatment he felt well, percussion only slightly dull, no crepitations, cough, or night-sweats. Weight 10 st. 4 lb.

Case 4.—Miss A. W., aged 20, had consolidation of the left apex, crepitations, with dullness on percussion. Evening temperature 101° F. She had T.B. in the sputum. At the end of six months' treatment the apex had cleared up, the crepitations were gone, and there were no T.B. in the sputum. Evening temperature normal. Weight increased from 7 st. 1½ lb. to 8 st. 3 lb.

Case 5.—Mr. J. H., aged 41. Consolidation right apex. T.B. present in sputum, crepitations, dullness on percussion. Weight 10 st. 9 lb. After six months' treatment the weight was 11 st. 6 lb. There were no T.B. in the sputum, no crepitations, and the percussion note was only slightly dull.

Case 6.—Mr. J. M., aged 25. Took ill in India where he had calcium injections. When I first saw him he had consolidation of the right apex. Two months afterwards the left base became affected. Patient stated he felt better after the injections and continued with them a long time, but he lost ground and died almost two years after coming home.

Case 7.—Mr. W. L., had been ill four months when he came to see me. Several of the family had died with tuberculosis. Three months after coming to see me he developed a cavity in the left apex. His illness ran a rapid course and he died in a few months. In this case the injections did not appear to have an appreciable effect on the disease.

The following cases were more advanced.

Case 8.—Mr. J. M., aged 19. Had tuberculosis of the bladder; pus, blood, and T.B. in the urine. Frequent micturition and losing flesh. Weight 6 st. 12 lb. Three months later the patient had gained 7 lb. and felt much better. At the end of seven months the urine contained no pus, blood, or T.B. The urine was passed only three or four times a day. Weight 8 st. 3 lb.

Case 9.—Mr. T. S., aged 32. Left apical cavity, tubercle of left vocal cord, T.B. in sputum. Three months after commencing treatment the lung dried up and the throat improved. The weight had risen from 9 st. 4½ lb. to 10 st. 3 lb. Eight months from commencement of treatment the throat was healed and there were no T.B. in the sputum. Patient avoided speaking as far as possible during that time.

Case 10.—Mr. P., aged 36. Had been unfit for work for two years, mostly confined to the house. The expectoration was purulent and contained T.B. There was a cavity at the left base. After six months' treatment the sputum was free from T.B. and the temperature was normal.

Case 11.—Boy, aged 14 years. Cavity left apex, T.B. in sputum. He did not react well to treatment. He stated, however, that he felt better after the injections, but unfortunately he lost ground and died after having been ill 14 months.

I consider that a review of these cases shows that we have in sodium morrhuate a valuable remedy for the treatment of tuberculosis, especially early cases.

Degree of Completeness of Collapse.

Table VII. shows that those patients with a complete collapse tend to do better than those with only a partial collapse. But it is possible that this result may not be due to the actual completeness of the collapse, but to the fact that in those cases in which a complete collapse has been obtained the disease before induction may have been less extensive than in those in which the collapse was only partial. These figures, therefore, cannot be used as an argument for dividing adhesions in pneumothorax cases in order to produce complete collapse—a question which does not come within the scope of this paper.

TABLE VII.

—	Complete collapse.	Partial collapse.
M.I.	51·4 per cent.	48·6 per cent.
I..	16·7 „	83·3 „
W.	14·3 „	85·7 „

Prognostic Importance of the Condition of the other Lung.

The question as to the extent and type of disease in the other lung in the presence of which it is permissible to induce an artificial pneumothorax is a very interesting one, but again does not come within our scope here. Our figures, however, in Table VIII. show that while bilateral disease is compatible with a good result in a large number of cases (37·9 per cent. of the "much improved" group had bilateral disease), yet its presence is against a good prognosis, as is shown by looking at the figures in a different way (Table VIII.A).

TABLE VIII. TABLE VIII.A.*

Patients.	Disease in other lung.	No disease in other lung.	Bilateral.	Unilateral.
	Per cent.	Per cent.	%	%
M.I.	37·9	62·1	14 (35)	23 (63·8)
I.	44·4	55·6	8 (20)	10 (27·7)
W.	85·7	14·3	18 (45)	3 (8·3)

* Of the 76 patients 40 had bilateral disease and 36 unilateral disease.

The Influence of Pleural Effusion.

The development of fluid in a pneumothorax cavity is generally held to have an adverse influence in the progress of the case. Our figures, however, do not bear this out. The idea of the evil effects of fluid has probably arisen from the fact that all types of fluid have been classed together without due regard to their nature and cause. We have very little actual knowledge as to their cause, but they can be classified according to their nature and behaviour. We find:—

1. Clear effusions, with small cell content, showing a high percentage of lymphocytes. These effusions, though persistent, do not tend to increase in amount; they are apparently more of the nature of transudates into an unnatural body cavity than actual inflammatory exudates. Their appearance is usually unaccompanied by constitutional disturbance.

2. Clear effusions, containing enough fibrin to clot, with a heavy cell content, showing a high percentage of lymphocytes and usually the presence of tubercle bacilli. They tend to increase in amount and to recur after removal, and must be regarded as definite inflammatory exudates from an invaded pleura. They probably occur after the pleura itself, previously free, has been invaded by the tuberculous process. Their onset is usually accompanied by constitutional disturbance which is often severe.

3. Cloudy or definitely purulent effusions with a heavy cell content, showing lymphocytes and polymorphonuclear leucocytes in varying proportions, with usually a preponderance of the latter. Tubercle bacilli are usually present, but the exudate is otherwise sterile. They tend to increase in amount and to recur after removal. They are sometimes purulent from the start, or No. 2 type may change into No. 3. Their onset is that of type No. 2. They tend to "point" sooner or later.

One cannot doubt that type No. 1 may be an innocuous phenomenon while type No. 3 may be very much the reverse, and therefore before the influence of pleural fluid in the progress of the case can be judged, the type of the fluid must be ascertained. Unfortunately in this present series of observations we have not recorded the different types of fluid, but the results show, we think, that the greater proportion must be of types No. 1 and No. 2.

Table IX. shows that the development of fluid has no deleterious influence on the immediate result; about the same percentage develop fluid in each class.

It has been said that exercise predisposes the patient to the development of fluid, but our figures in Table X. do not agree with this. The numbers do not correspond with those in Table IX., for in Table X. we have not included those cases in which fluid was present from the start of the artificial pneumothorax, as in gas replacements of pleural effusions, and spontaneous hydropneumothoraces subsequently converted into artificial ones. The development of fluid therefore is not determined by exercise, but more probably by the degree of involvement of the pleura by active tuberculosis, either present at the outset or occurring subsequently.

Tables XI. and XII. show that the presence of pleural fluid has no influence on the capacity for work or the likelihood of relapse. The length of time spent in relapse and the chance of relapse is equal for those with and without fluid. The figures in Table XI. do not refer to the total number of cases in each class, but only to those who relapsed in each class. We think that these figures are encouraging, as they show that, at any rate, non-purulent effusion, although a common complication of artificial pneumothorax, is not a serious one.

Disappearance of Tubercle Bacilli from the Sputum.

Table XIII. shows that the disappearance of tubercle bacilli from the sputum as a result of the induction of an artificial pneumothorax is of the highest prognosis in his own class is justified for a patient who goes through all grades of labour without relapse and is discharged "much improved," then it follows that this test of ability to do a certain grade of walking exercise without relapse must be a valuable guide to the physician in the early stages of treatment.

TABLE I.

TABLE III.

Patients who Reached Three Miles Daily (Men) and Two Miles Daily (Women) Without Relapsing: 46 out of 73 = 63·0 per cent.

Of these, the number discharged as—

M.I. was 33 or 71·7 per cent.
I. „ 9 „ 19·6 „
W. „ 4 „ 8·7 „

—i.e., 33 out of 46 patients reaching three miles (men) or two miles (women) without relapsing were discharged as M.I.

The chances of such a patient being discharged as M.I. are practically 2·4 to 1 in favour; or the chances of such a patient being discharged as worse are practically 10 to 1 against.

Patients who Relapsed Before Reaching Three Miles Daily (Men) or Two Miles Daily (Women): 27 out of 73 = 37 per cent.

Of these, the number discharged as—

M.I. was 4 or 14·8 per cent.
I. „ 9 „ 33·3 „
W. „ 14 „ 51·9 „

The chances of such a patient being discharged as M.I. are practically 6 to 1 against; or the chances of such a patient being discharged as worse are practically equal odds.

65 per cent. of patients who are discharged as much improved do *not* relapse at all. Of the 35 per cent. who do relapse, 70 per cent. do not do so until they have passed three miles daily (men) or two miles daily (women).

27·7 per cent. of patients who are discharged as improved do *not* relapse at all. Of the 72·3 per cent. which do relapse, 69·2 per cent. do so before passing three miles daily (men) or two miles daily (women).

5·5 per cent. of patients who are discharged as worse do *not* relapse at all. Of the 94·5 per cent. which do relapse, 82 per cent. break down before passing three miles daily (men) or two miles daily (women).

Temperature Types of Different Groups.

In our study of temperatures we have investigated certain points, and, in order to make these clear, we submit the following definitions:—

Regularity.—A regular temperature is taken as one in which the morning and evening range only varies by a fraction of a degree over a considerable period of time. A periodic temperature is regular, provided the amplitude of the waves remains fairly constant, and provided the swing on the crests does not vary much from the swing in the troughs. A spiky temperature is irregular.

Swing.—The swing is the daily fluctuation which occurs in the temperature, as measured by the difference between the morning and evening records.

Periodicity.—A temperature is said to be periodic when the mean of the morning and evening temperatures rises and falls at constant intervals. Comparatively slight evidences of periodicity have been accepted.

Our study of temperature records in artificial pneumothorax cases does not disclose any startling facts. Table IV.A shows, as might be expected, that those patients who do well tend to have the more regular temperature, which presumably indicates that their resistance to the toxins of tuberculosis is stable, and not likely to be upset by slight alterations in their daily routine. The daily swing is apparently of no prognostic importance, according to the figures in Table IV.B. This is interesting, since a free swing in an ordinary case of pulmonary tuberculosis is usually regarded as a bad omen, and is certainly pathological. The menstrual periodicity in the temperature records of a high percentage of all tuberculous women is so marked that it obscures the significance of this feature, but the figures in Table IV.C show that a definite periodicity suggests a bad prognosis in men.

Extending our observations to the characters of the temperature record during relapses, Tables V. and VI. show that the combination of a sudden rise with fall by crisis is most frequent in the "much improved" class, and that in the "much improved" and "improved" classes 50 per cent. of the sudden rise temperatures come down by crisis; in the "worse" class only about 20 per cent. do so. The more abrupt the start and finish of the temperature relapse the shorter is it likely to be. This, coupled with our observation that the shorter the relapse the better the prognosis, agrees with Marcus Paterson's teaching that a smart temperature reaction to increased exercise in many cases does no harm to the patient. Such a short, sharp temperature relapse would seem to indicate a brisk and healthy response on the part of the patient to increased toxin absorption, and it is suggested that a more sluggish temperature response is to be regarded with suspicion and is not a true index of the degree of increase of the toxæmia.

Degree of Completeness of Collapse.

Table VII. shows that those patients with a complete collapse tend to do better than those with only a partial collapse. But it is possible that this result may not be due to the actual completeness of the collapse, but to the fact that in those cases in which a complete collapse has been obtained the disease before induction may have been less extensive than in those in which the collapse was only partial. These figures, therefore, cannot be used as an argument for dividing adhesions in pneumothorax cases in order to produce complete collapse—a question which does not come within the scope of this paper.

TABLE VII.

Prognostic Importance of the Condition of the other Lung.

The question as to the extent and type of disease in the other lung in the presence of which it is permissible to induce an artificial pneumothorax is a very interesting one, but again does not come within our scope here. Our figures, however, in Table VIII. show that while bilateral disease is compatible with a good result in a large number of cases (37·9 per cent. of the "much improved" group had bilateral disease), yet its presence is against a good prognosis, as is shown by looking at the figures in a different way (Table VIII.A).

* Of the 76 patients 40 had bilateral disease and 36 unilateral disease.

The Influence of Pleural Effusion.

The development of fluid in a pneumothorax cavity is generally held to have an adverse influence in the progress of the case. Our figures, however, do not bear this out. The idea of the evil effects of fluid has probably arisen from the fact that all types of fluid have been classed together without due regard to their nature and cause. We have very little actual knowledge as to their cause, but they can be classified according to their nature and behaviour. We find:—

1. Clear effusions, with small cell content, showing a high percentage of lymphocytes. These effusions, though persistent, do not tend to increase in amount; they are apparently more of the nature of transudates into an unnatural body cavity than actual inflammatory exudates. Their appearance is usually unaccompanied by constitutional disturbance.

2. Clear effusions, containing enough fibrin to clot, with a heavy cell content, showing a high percentage of lymphocytes and usually the presence of tubercle bacilli. They tend to increase in amount and to recur after removal, and must be regarded as definite inflammatory exudates from an invaded pleura. They probably occur after the pleura itself, previously free, has been invaded by the tuberculous process. Their onset is usually accompanied by constitutional disturbance which is often severe.

3. Cloudy or definitely purulent effusions with a heavy cell content, showing lymphocytes and polymorphonuclear leucocytes in varying proportions, with usually a preponderance of the latter. Tubercle bacilli are usually present, but the exudate is otherwise sterile. They tend to increase in amount and to recur after removal. They are sometimes purulent from the start, or No. 2 type may change into No. 3. Their onset is that of type No. 2. They tend to "point" sooner or later.

One cannot doubt that type No. 1 may be an innocuous phenomenon while type No. 3 may be very much the reverse, and therefore before the influence of pleural fluid in the progress of the case can be judged, the type of the fluid must be ascertained. Unfortunately in this present series of observations we have not recorded the different types of fluid, but the results show, we think, that the greater proportion must be of types No. 1 and No. 2.

Table IX. shows that the development of fluid has no deleterious influence on the immediate result; about the same percentage develop fluid in each class.

It has been said that exercise predisposes the patient to the development of fluid, but our figures in Table X. do not agree with this. The numbers do not correspond with those in Table IX., for in Table X. we have not included those cases in which fluid was present from the start of the artificial pneumothorax, as in gas replacements of pleural effusions, and spontaneous hydropneumothoraces subsequently converted into artificial ones. The development of fluid therefore is not determined by exercise, but more probably by the degree of involvement of the pleura by active tuberculosis, either present at the outset or occurring subsequently.

Tables XI. and XII. show that the presence of pleural fluid has no influence on the capacity for work or the likelihood of relapse. The length of time spent in relapse and the chance of relapse is equal for those with and without fluid. The figures in Table XI. do not refer to the total number of cases in each class, but only to those who relapsed in each class. We think that these figures are encouraging, as they show that, at any rate, non-purulent effusion, although a common complication of artificial pneumothorax, is not a serious one.

importance in prognosis. These figures speak for themselves and require no elaboration; and it seems that the disappearance of bacilli will occur even though there be disease in the opposite lung, and in cases where only a partial collapse has been obtained. For of the 35 "much improved" cases who lost their bacilli 15 had bilateral disease and 17 had a partial collapse; of the 9 "improved" cases 3 had bilateral disease and 6 a partial collapse; of the 5 of the "worse" class 1 had bilateral disease and 4 a partial collapse.

Importance of Changes in the Weight of the Patient.

Table XIV. shows that a steady gain in weight is valuable evidence of the satisfactory response of the patient to treatment. It is important to notice that this table does not refer to the changes in weight occurring from the time of induction of the pneumothorax but from the commencement of sanatorium treatment, which was generally three to four months later.

TABLE XIV.

—	Gain in weight.	Steady.	Loss.

Patients without fluid, 8	105

We also found that those patients who relapsed or had pleural fluid gained weight or lost according to the class that they were in, uninfluenced by the relapse or the fluid. The explanation of this somewhat surprising fact appears to be, as is shown in Tables XV., XVI., and XVII., that gain of weight was more probable in those who had the longer stay in the sanatorium, which was the case with those who relapsed and those who had pleural fluid.

A careful inspection of these tables will reveal a definite correlation between the length of stay and the increase in weight. Only one exception occurs—namely, that with the patients of the "worse" class who lost weight; the probable explanation in this case is that they had entered upon a pyrexial relapse which prevented their being discharged, and at the conclusion of which they were removed to an infirmary as being unlikely to derive benefit from sanatorium treatment. Apart from this one class, however, the correlation is valid. Remembering the limited number of cases which are being dealt with, one cannot expect to find an exact quantitative correlation between the length of stay and the increase in weight. but the fact that the variation uniformly occurs in the same direction serves to show that the relationship is not a fictitious one.

Conclusions.

1. If a relapse occurs during the exercise treatment of an artificial pneumothorax case, there are two salient points of interest: (*a*) the longer it is, the worse is the prognosis; (*b*) the earlier it occurs the less likely is the patient to do well. A relapse which takes place for the first time when the patient has reached an advance grade of exercise seems to be of singularly little importance. We may say that if a patient is going to do badly, he will relapse early; if he is going to do well, he will relapse late or not at all.

2. A regular temperature is of good prognostic significance; an irregular one is the reverse. In men a periodic temperature is an unfavourable feature. The daily variation seems to have no special significance.

3. We find that the patients who have done well have more often had a complete collapse than those who have done badly. In the absence of any quantitative estimation of the degree of completeness of the collapse, and in view of the fact that the extent of disease has varied considerably in our patients, we refrain from drawing any conclusions as to the meaning of this observation.

4. It is clear that a considerable number of patients with bilateral disease are capable of responding well to artificial pneumothorax treatment, and of reacting favourably to the system of graduated exercise which is given to them preparatory to their ingress once more into the world of activity.

5. It is probably fair to say that the development of pleural fluid—so long as it be not of a purulent type—is a matter of supreme indifference to the prognosis of the case. It is interesting, too, to note we have no evidence which suggests that the advent of fluid is likely to be occasioned by exercise.

6. Persistence of tubercle bacilli in the sputum after the induction of artificial pneumothorax is a feature of bad omen. Our figures show that if the sputum remains positive the chances are 10 to 1 against the patient being discharged as much improved.

7. One of the most valuable criteria of the patient's reaction to treatment is the change in weight which occurs after his admission to the sanatorium. Though it is not uncommon for patients, even in the worse class, to gain a little in weight, it is very uncommon for those who are going to do well to lose any. How true this is can be seen from our tables, which show that if a patient loses weight progressively after starting exercise the chances are 37 to 1 against his being discharged as much improved. An early loss in weight should prove a most valuable arresting signal. and should lead to a careful reconsideration of the further treatment of the patient.

8. The longer the patient's stay in the sanatorium the more weight is he likely to gain or the less is he

ikely to lose. Though not desiring to extol sanatorium treatment, above other methods, we consider that this fact reflects very favourably on this form of treatment.

In this paper we have been concerned with an examination of the results obtained by the graduated exercise treatment of patients on whom an artificial pneumothorax has been induced either by choice or by necessity. We do not wish to advocate this method, as, from the nature of the cases, it has been more or less forced on us, but we would point out that under it no fewer than 49 per cent. of an unselected, consecutive series of cases have been discharged as much improved and capable of earning their living in the world. With the indications which we have gathered from this examination, with the danger signals more clearly pointed out than heretofore, and with the elucidation of certain promising features to give us confidence in the pursuit of treatment, we feel that it should not be impossible in the future to secure results which will be even more hopeful than those obtained in our present series.

ARTIFICIAL PNEUMOTHORAX.

By L. S. T. BURRELL, M.D. Camb.,
F.R.C.P. Lond.,
PHYSICIAN TO THE BROMPTON HOSPITAL; ASSISTANT
PHYSICIAN TO THE WEST LONDON HOSPITAL.

In 1922 Dr. A. S. MacNalty and I issued a report[1] to the Medical Research Council on artificial pneumothorax. The present paper is a second report to the Council on the same subject, and I propose to give the results up to date of my first 250 cases and to consider the dangers and complications which may arise during the treatment. In conclusion, I shall discuss the value and limitation of artificial pneumothorax in the treatment of pulmonary disease.

Results of Treatment.

In order to analyse the results of treatment I divided my cases into the following groups:—

A. Patients with little or no powers of resistance, and a rapidly spreading acute infection.

B. Patients with good powers of resistance and in the early stage of the disease.

C. Patients with medium resistance who have failed to improve after other treatment. This group is subdivided into:—

(1) Involvement of one lung only; (2) some involvement of the better lung; and (3) involvement of a third or more of the better lung.

D. Non-tuberculous cases.

Tubercle bacilli were found in the sputum in all cases except those in Group D.

The following tables give an analysis of my first series (150 cases) arranged according to the above groups, and show the result of treatment in May, 1922, when the previous report was written, and the condition of the same patients in January, 1924. By arrested is meant disappearance of tubercle bacilli from the sputum for at least six months, no apparent active disease, and ability to do full work.

From the 107 cases in Table I. it will be seen that the results in Group C 1 are good and are remaining good, especially when one remembers that in each of these cases artificial pneumothorax was induced only because the patient was not making good progress under other treatment. When we turn to Groups C 2 and C 3 the results are not good. This one would expect, because the pneumothorax rests only one lung, and it is therefore only part of the diseased area that is having treatment in cases of bilateral disease.

importance in prognosis. These figures speak for themselves and require no elaboration; and it seems that the disappearance of bacilli will occur even though there be disease in the opposite lung, and in cases where only a partial collapse has been obtained. For of the 35 "much improved" cases who lost their bacilli 15 had bilateral disease and 17 had a partial collapse; of the 9 "improved" cases 3 had bilateral disease and 6 a partial collapse; of the 5 of the "worse" class 1 had bilateral disease and 4 a partial collapse.

TABLE XIII.

Total number of cases whose records with regard to presence or absence of tubercle bacilli in sputum are known	75	
Number of patients whose sputum became negative after A.P.	49	(65·3 per cent.)
Of these, discharged as much improved.	35	(71·4 ,, ,,)
,, ,, ,, ,, improved	9	(18·4 ,, ,,)
,, ,, ,, ,, worse	5	(10·2 ,, ,,)
Number of patients whose sputum remained positive after A.P.	26	(34·7 per cent.)
Of these, discharged as much improved.	2	(7·7 ,, ,,)
,, ,, ,, ,, improved	8	(30·8 ,, ,,)
,, ,, ,, ,, worse	16	(61·5 ,, ,,)

Importance of Changes in the Weight of the Patient.

Table XIV. shows that a steady gain in weight is valuable evidence of the satisfactory response of the patient to treatment. It is important to notice that this table does not refer to the changes in weight occurring from the time of induction of the pneumothorax but from the commencement of sanatorium treatment, which was generally three to four months later.

TABLE XIV.

—	Gain in weight.	Steady.	Loss.
	Per cent.	Per cent.	Per cent.

Patients without fluid, 8	105

We also found that those patients who relapsed or had pleural fluid gained weight or lost according to the class that they were in, uninfluenced by the relapse or the fluid. The explanation of this somewhat surprising fact appears to be, as is shown in Tables XV., XVI., and XVII., that gain of weight was more probable in those who had the longer stay in the sanatorium, which was the case with those who relapsed and those who had pleural fluid.

A careful inspection of these tables will reveal a definite correlation between the length of stay and the increase in weight. Only one exception occurs—namely, that with the patients of the "worse" class who lost weight; the probable explanation in this case is that they had entered upon a pyrexial relapse which prevented their being discharged, and at the conclusion of which they were removed to an infirmary as being unlikely to derive benefit from sanatorium treatment. Apart from this one class, however, the correlation is valid. Remembering the limited number of cases which are being dealt with, one cannot expect to find an exact quantitative correlation between the length of stay and the increase in weight, but the fact that the variation uniformly occurs in the same direction serves to show that the relationship is not a fictitious one.

Conclusions.

1. If a relapse occurs during the exercise treatment of an artificial pneumothorax case, there are two salient points of interest: (*a*) the longer it is, the worse is the prognosis; (*b*) the earlier it occurs the less likely is the patient to do well. A relapse which takes place for the first time when the patient has reached an advance grade of exercise seems to be of singularly little importance. We may say that if a patient is going to do badly, he will relapse early; if he is going to do well, he will relapse late or not at all.

2. A regular temperature is of good prognostic significance; an irregular one is the reverse. In men a periodic temperature is an unfavourable feature. The daily variation seems to have no special significance.

3. We find that the patients who have done well have more often had a complete collapse than those who have done badly. In the absence of any quantitative estimation of the degree of completeness of the collapse, and in view of the fact that the extent of disease has varied considerably in our patients, we refrain from drawing any conclusions as to the meaning of this observation.

4. It is clear that a considerable number of patients with bilateral disease are capable of responding well to artificial pneumothorax treatment, and of reacting favourably to the system of graduated exercise which is given to them preparatory to their ingress once more into the world of activity.

5. It is probably fair to say that the development of pleural fluid—so long as it be not of a purulent type—is a matter of supreme indifference to the prognosis of the case. It is interesting, too, to note we have no evidence which suggests that the advent of fluid is likely to be occasioned by exercise.

6. Persistence of tubercle bacilli in the sputum after the induction of artificial pneumothorax is a feature of bad omen. Our figures show that if the sputum remains positive the chances are 19 to 1 against the patient being discharged as much improved.

7. One of the most valuable criteria of the patient's reaction to treatment is the change in weight which occurs after his admission to the sanatorium. Though it is not uncommon for patients, even in the worse class, to gain a little in weight, it is very uncommon for those who are going to do well to lose any. How true this is can be seen from our tables, which show that if a patient loses weight progressively after starting exercise the chances are 37 to 1 against his being discharged as much improved. An early loss in weight should prove a most valuable arresting signal, and should lead to a careful reconsideration of the further treatment of the patient.

8. The longer the patient's stay in the sanatorium the more weight is he likely to gain or the less is he

likely to lose. Though not desiring to extol sanatorium treatment, above other methods, we consider that this fact reflects very favourably on this form of treatment.

In this paper we have been concerned with an examination of the results obtained by the graduated exercise treatment of patients on whom an artificial pneumothorax has been induced either by choice or by necessity. We do not wish to advocate this method, as, from the nature of the cases, it has been more or less forced on us, but we would point out that under it no fewer than 49 per cent. of an unselected, consecutive series of cases have been discharged as much improved and capable of earning their living in the world. With the indications which we have gathered from this examination, with the danger signals more clearly pointed out than heretofore, and with the elucidation of certain promising features to give us confidence in the pursuit of treatment, we feel that it should not be impossible in the future to secure results which will be even more hopeful than those obtained in our present series.

ARTIFICIAL PNEUMOTHORAX.

By L. S. T. BURRELL, M.D. CAMB.,
F.R.C.P. LOND.,
PHYSICIAN TO THE BROMPTON HOSPITAL; ASSISTANT PHYSICIAN TO THE WEST LONDON HOSPITAL.

IN 1922 Dr. A. S. MacNalty and I issued a report[1] to the Medical Research Council on artificial pneumothorax. The present paper is a second report to the Council on the same subject, and I propose to give the results up to date of my first 250 cases and to consider the dangers and complications which may arise during the treatment. In conclusion, I shall discuss the value and limitation of artificial pneumothorax in the treatment of pulmonary disease.

Results of Treatment.

In order to analyse the results of treatment I divided my cases into the following groups:—

A. Patients with little or no powers of resistance, and a rapidly spreading acute infection.

B. Patients with good powers of resistance and in the early stage of the disease.

C. Patients with medium resistance who have failed to improve after other treatment. This group is subdivided into:—

(1) Involvement of one lung only; (2) some involvement of the better lung; and (3) involvement of a third or more of the better lung.

D. Non-tuberculous cases.

Tubercle bacilli were found in the sputum in all cases except those in Group D.

The following tables give an analysis of my first series (150 cases) arranged according to the above groups, and show the result of treatment in May, 1922, when the previous report was written, and the condition of the same patients in January, 1924. By arrested is meant disappearance of tubercle bacilli from the sputum for at least six months, no apparent active disease, and ability to do full work.

From the 107 cases in Table I. it will be seen that the results in Group C 1 are good and are remaining good, especially when one remembers that in each of these cases artificial pneumothorax was induced only because the patient was not making good progress under other treatment. When we turn to Groups C 2 and C 3 the results are not good. This one would expect, because the pneumothorax rests only one lung, and it is therefore only part of the diseased area that is having treatment in cases of bilateral disease.

As one would expect, the more extensive the disease the less chance there is of producing an efficient pneumothorax, and it will be seen that I failed to produce an efficient one in 17 cases (19·3 per cent.) out of the 88 in Group C 1; in 19 (23·7 per cent.) out of the 80 in C 2; and in 15 (41·6 per cent.) out of the 36 in C 3. If Table VI. is compared with Table III. it will also be seen that there were far fewer failures in the last series. Of the first 150 cases I failed to produce any pneumothorax at all in 23. Of the next 100 cases I failed in 6, and since then I have treated 94 more cases with 7 failures. At present, therefore, the percentage of complete failures is 6·6.

The figures in Table IV. are very similar to those in Table I., and show good results in Group C 1, but very bad in C 3, and poor in C 2. This supports the opinion formed after consideration of the first 150 cases, that for the most part it is only in unilateral cases that really good results are obtained by artificial pneumothorax. In many of the bilateral cases the immediate results are excellent, and in some cases dramatic, but after a time they usually relapse so that the late results are not good. The following two cases illustrate the good results obtained at first in bad cases; results which must be attributed to the treatment, for the improvement followed so immediately after its beginning.

Case 1.—A woman, aged 38, developed tuberculosis of the left lung in 1916 and went to a sanatorium for nine months. She improved and kept fairly well until 1919, when she began to lose ground, and in February, 1920, she took to bed with an evening temperature of 101°–102°F. She steadily grew worse, and in August she was much wasted, was still running the same temperature, and had copious expectoration. There were signs of disease all over the left lung, and moist râles were heard at the right apex, both in front and behind. X rays showed disease all over the left lung and considerable infiltration of the upper and middle zones on the right side. Left artificial pneumothorax was induced, and the temperature at once fell to normal, the cough improved, and the sputum lessened. In September she got up, and later was able to take short walks. In January, 1921, however, the high temperature returned, and the treatment was stopped owing to spread of disease on the right side. She gradually became worse and died in June, 1921.

Case 2.—A woman of 36 contracted tuberculosis of the left lung in 1919, and after treatment at home went to a sanatorium for three months in 1920, and then had a voyage to Australia for three months. On her return she was much wasted, and had a severe cough with sputum loaded with tubercle bacilli. There were moist râles all over the left lung, and on the right side moist sounds were heard in front to the third rib in the nipple line, and behind to the spine of the scapula. X rays showed much disease in both lungs. Her weight, which normally was 130 lb., was then only 109 lb.; she looked toxic and had a swinging temperature. In August, 1921, I induced a left pneumothorax and gave small frequent refills. She gradually improved, tubercle bacilli became fewer and fewer, and eventually disappeared from the sputum. For a time the right (untreated) lung appeared to improve, and her weight went up to 121 lb. In February, 1923, however, she had a febrile attack and rapidly became worse. There was an increase of signs on the right side, and the refills were stopped. Now (January, 1924) her weight is 109 lb., she is afebrile whilst in bed, but has an evening temperature if allowed up. The left lung is re-expanded and fibrotic, but the disease has spread over the right side. The question of inducing a right pneumothorax is being considered, and she herself is anxious for it to be done as she felt so much benefit from the first pneumothorax.

Complications and Dangers.

Effusion.—The development of pleural effusion is a frequent and important complication of artificial pneumothorax treatment. Forty of my first 150 and 26 of my next 100 cases developed it. Of the last 94 cases 19 have already developed effusion, and more are certain to develop it later, as in many cases the treatment has only recently been started. It would seem, therefore, that increased experience does not affect the incidence of this complication. I have not found that such means as warming the gas or using some gas other than air have any effect in preventing the formation of these effusions.

Table VII.—*Showing the Time After Starting the Treatment when the Effusion Appeared in My First 250 Cases.*

Month—	A.	C 1.	C 2.	C 3.	D.	Total.
1st	2	1	2	4	1	10
2nd and 3rd ..	—	4	9	3	—	16
4th to 6th ..	1	8	9	1	—	19
7th to 12th ..	—	8	8	—	—	16
13th to 18th ..	—	3	1	—	—	4
19th to 24th ..	—	—	1	—	—	1
Total	3	24	30	8	1	66

Thus 24 (33·8 per cent.) of the 71 cases in Group C 1, 30 (49·1 per cent.) of the 61 in C 2, and 8 (36·1 per cent.) of the 21 in C 3 developed pleural effusion. The smaller percentage in Group C 3 does not indicate that advanced cases are less liable to develop effusion than others, for many of these cases either died soon after the treatment started or the treatment was stopped early owing to the advanced disease. Of the 14 cases in Group C 3 in which the treatment was kept up for more than 6 months 8 (57·1 per cent.) developed effusion.

Total	24	30	47	31

It would seem, therefore, that in Group C 1 cases with effusion do as well as those without. In Group C 2, however, those patients who developed effusion did less well than the others. In 14 cases the effusion turned into tuberculous pus. Of these 7 were in Group C 1, 4 being arrested, 1 better, and 2 worse. Excluding those cases in which artificial pneumothorax was induced to replace effusion, I have treated 20 non-tuberculous cases by pneumothorax, and except in one case of an acute abscess, where X rays showed a small pool of fluid not sufficient to fill in the costo-diaphragmatic angle and which was absorbed in a few days, not one of these non-tuberculous cases developed effusion. Moreover, the cytology in all cases when fluid was removed showed a big lymphocytosis, and no organism except the tubercle bacillus was found in any case. Tubercle bacilli were not found as a rule in the early stages of the effusion, but they invariably appeared in effusions of long standing. Tuberculous pleurisy is a common complication of pulmonary tuberculosis, and if the visceral and parietal pleura are separated by a pneumothorax so that any exudate cannot produce adherent pleura one would expect the pleura to weep and cause an effusion. For these reasons I am inclined to believe that these effusions are tuberculous exudates, and are common in cases of pneumothorax because the visceral and parietal pleuræ are not in contact.

Pleural shock or *gas embolism* may occur during the production of a pneumothorax or during a refill. Fortunately, these accidents are very rare. Out of 344 cases (and if one includes cases in which a bilateral pneumothorax was induced and cases where the first attempt to produce a pneumothorax failed and other attempts were made, 467 punctures of the pleura with the purpose of inducing a pneumothorax) I have had one case of fatal pleural shock, and this was at the second attempt. In one case the patient became faint and almost pulseless for a few minutes, and in three others the patients complained of a temporary feeling of faintness. Out of 5157 refills 9 complained of a temporary faintness, and one became faint and nearly pulseless for a few minutes during a refill. In one case the symptoms were more alarming: during the third refill the patient felt giddy, after the fourth refill she had a sudden pain over the heart and could not breathe and lost consciousness for about two minutes. During the fifth refill she suddenly gave a gasp, became blue and almost pulseless, and afterwards said she felt as if about to die. She did not actually lose consciousness and was all right half an hour later. The treatment was discontinued. In one other case during the third year of treatment the patient became giddy a few minutes after a refill and felt pins and needles down one side and lost her sight for about ten minutes, but did not lose consciousness. This last case, I think, was one of gas embolism, but I feel sure that all cases are not due to embolism and that pleural shock exists. Often on giving a local anæsthetic when there can be no question of embolism the patient complains of a sickly feeling as soon as the small hypodermic needle touches the pleura. Moreover, symptoms of shock are apt to recur in the same patient, apparently because the pleura is hypersensitive. This would not be the case if the symptoms were due to gas embolism.

In two of my cases a spontaneous pneumothorax occurred on the better side and led to a fatal issue. In six cases there was a *rupture of the visceral pleura* on the treated side leading to pyopneumothorax. Two of these cases were in non-tuberculous patients and both recovered. The others were cases of pulmonary tuberculosis, three proved fatal and the other is dying. It often happens that a small amount of *surgical emphysema* occurs, but in only one of my cases was it serious. In this case two attempts were made to induce an artificial pneumothorax, but they failed owing to adherent pleura. 24 hours later the patient complained of pain across the chest, and some surgical emphysema was found in the chest and neck. Two days later it had spread all over the chest and abdomen. Both arms and hands were affected, and the neck, face, and scalp were much swollen with the emphysema, and he could hardly see out of his eyes. There was no emphysema below Poupart's ligament. There was no pyrexia, and no pain or symptoms except a slight choking feeling. After three days the emphysema began to subside, and it had completely disappeared in a week.

Value and Limitations of the Treatment.

From a study of these cases it seems to me that artificial pneumothorax is a safe and satisfactory method of resting a diseased lung. As it is impossible to rest both lungs at once one would expect the results to be much better in unilateral than in bilateral cases, and this is found to be the case. Indeed, a highly active and extensive lesion in one lung readily yields to pneumothorax treatment, and the case does better than one with smaller and less active lesions in both lungs. The great difference between the results in unilateral and bilateral disease is, I think, strong evidence that the pneumothorax is the important factor in checking the disease. But bilateral disease is not necessarily a contra-indication. When the lung with most disease is collapsed the other lung usually improves at first, just as in other tuberculous lesions when the main focus is removed. For instance, ulceration of the bladder may heal after removal of a tuberculous kidney. After a time, however, disease frequently spreads in the untreated lung, and although on allowing re-expansion of the diseased lung there is usually improvement on both sides, and the case may be converted into a chronic fibroid type lasting several years, the ultimate prognosis is not good. If activity persists in the untreated lung after re-expansion of the other it is sometimes possible to induce a pneumothorax on that side. This often gives very good immediate results, but here again the ultimate results are disappointing. Even in very advanced cases life may be considerably prolonged by artificial pneumothorax.

It is sometimes said that these unilateral cases which do so well with pneumothorax treatment are just the type which do well on any treatment; but these pneumothorax patients had had other treatment, and pneumothorax was induced only because they were not doing well under it. It is true that a patient under hospital or sanatorium treatment may improve after doing badly at first, but the number of successful results in pneumothorax cases *who were doing badly under other treatment* is worthy of note.

Indications for Artificial Pneumothorax.

The question arises, When should an artificial pneumothorax be advised? Clearly it is wrong to wait until all other treatment has failed and the patient is in an advanced stage of disease. On the other hand, if the patient is treated properly and at once, pneumothorax treatment does not, as a rule, become necessary.

There are two factors which affect the treatment of the earlier cases. In the first place, the importance of rest during active disease is not appreciated; patients who ought to be in bed are walking about and even playing games. Bed is considered weakening. Fresh air and good feeding are, I agree, very necessary, but far more important is rest. In the second place, the gravity of the disease in the early stages is often underrated. A certain number of cases do undoubtedly recover without any treatment whatever, but many do not. In England and Wales in 1922 over 55,000 people were notified as having pulmonary tuberculosis, and over 42,000 died of it. Treatment is satisfactory only in early cases, and it is therefore these cases that most urgently require treatment, which should be kept up until the disease is arrested. It should not be stopped when the patient is better but not well.

As I have said, if the case comes under observation early artificial pneumothorax is not usually required, because a period of rest followed by sanatorium treatment is generally sufficient to effect arrest. But if in spite of rest the patient fails to improve or becomes worse, then I should advise rest of the diseased lung by means of artificial pneumothorax, in addition to the other treatment. In favour of this I would urge: (1) It is a safe method of treatment; (2) unilateral cases do very well, even those which were getting worse under other treatment; (3) the earlier the pneumothorax is induced the less chance there is of finding adhesions which may prevent a satisfactory collapse; (4) every case of advanced disease has passed through an early stage. Whilst encouraging the patient and taking an optimistic view the physician should remember that the great object of treatment is to prevent the disease from getting into the incurable stage. A patient is often too bad for treatment but never not bad enough.

In bilateral cases, if there is not much activity in the better lung, satisfactory results may be obtained, but the better lung should be carefully watched, and if the disease spreads in it pneumothorax treatment should be stopped. In non-tuberculous cases very good results are obtained in cases of abscess of lung, repeated hæmoptysis, and recurrent pleural effusion. In cases of bronchiectasis there is often improvement, but the results are not so good as there is usually a considerable amount of adherent pleura, and also in most cases the disease is bilateral.

Artificial pneumothorax should be regarded not as a cure for tuberculosis of lung, but as a safe method of resting the diseased part, and it should be used in conjunction with other methods of treatment.

Finally, I would say that the success of the treatment is largely dependent on really keeping the lung at rest, taking each case individually and arranging the dosage and intervals between the refills according to the peculiarities of the individual patient.

A CASE OF GAUCHER'S ANÆMIA.

BY NORAH H. SCHUSTER, M.B., CH.B. MANCH.,
PATHOLOGIST TO THE INFANTS HOSPITAL, WESTMINSTER, S.W.

Gaucher's anæmia has been studied in all European countries and America, so that its incidence is evidently widespread, and probably not so rare as heretofore imagined. Reuben, in 1914, analysed 14 cases of children dating from Gaucher's original paper in 1886; since then 10 have been definitely claimed, mostly in the States, and three or four unproven diagnoses have also been made. The following case is considered as belonging to the same group, though it shows some variation from the characteristic story.

The disease occurred in a girl of 1 year 10 months who was perfectly well until a fortnight before admission to hospital. She then suddenly seemed to lose colour, became apathetic and lost weight. She vomited twice and was rather constipated. There was no history of hæmorrhage from any source. She was the first and only child of young healthy parents, and though always under-weight had shown normal muscular, bone, and mental development.

Condition on Admission.—On examination she was noticed to be of a golden-yellow hue with pale mucous membranes and a fair quantity of subcutaneous fat. Her weight was 18 lb. 7 oz. There was no conjunctival thickening. The condition of the mouth was healthy except that the tonsils were enlarged. The chest showed no abnormality. Small glands were palpable in the axilla. The abdomen was distended by flatulence. There was a large, hard, tender spleen reaching to the level of umbilicus. The nervous system was normal. The urine contained acetone and a few red cells, but showed no other abnormality. The fæces contained no occult blood. The Wassermann reaction was negative and the fragility of the red cells was not increased. The blood report was as follows: red cells, 1,070,000 per c.mm.; white cells, 14,400 per c.mm.; Hb, 28 per cent.; colour index, 1·4. Differential count: Polymorphonuclears, 56 per cent.; lymphocytes, 39 per cent.; transitional, 4 per cent.; mast cells, 1 per cent. The red cells were variable in size with many myelocytes but regular in shape. Polychromatophilia was common, but no punctate basophilia was observed. One nucleated red cell was noted in the film. In several films examined only one myelocyte of an adult type was found. The temperature and pulse and respiration were all irregular, the temperature rising to 101° F. each day, and the pulse varying between 120 and 170 per minute. The patient remained one week in hospital, during which time she failed to respond to treatment with arsenic, but did not show any rapid change for the worse until the seventh day, when she died suddenly with acute œdema of the lungs. A few days before this, four or five minute petechiæ, which quickly became brown and faded, appeared in the skin over the abdomen.

Post-mortem Examination.—The adenoid pad and tonsils were slightly enlarged and one tonsil contained two small purulent foci. The lungs showed considerable œdema, but no pneumonia or hæmorrhages. The heart muscle presented obvious fatty degeneration but no other lesion. In the abdomen there was gaseous distension of the stomach and intestines. There was no lymphoid hyperplasia. The liver was slightly enlarged and showed no naked-eye changes. Free iron was just demonstrable. The spleen was attached by recent adhesions to the stomach and posterior wall of the abdomen. It was much enlarged and weighed 8 oz. The organ was firm and the notches prominent. On section the pulp was firmer than normal and bright red in colour. The Malpighian bodies were not enlarged. A large and a small white infarct were present. Free iron could be demonstrated. The kidneys were very pale, but otherwise normal to the naked eye. The thymus was not enlarged. The endocrine glands showed no change. The cervical lymph glands were all enlarged, pale, and firm and were quite discrete. The mediastinal and mesenteric glands were normal in size, but there was enlargement of those near the spleen and in the retro-peritoneal tissue. The bone-marrow was pink in colour, but did not appear to be hyperplastic. Cultures were taken from the splenic pulp and found to be sterile.

Microscopical Examination.—The low-power view of sections of the spleen presented a series of rounded spaces which were well defined by fibrous tissue, and partially filled with Gaucher cells. There were so many of these half-empty spaces that the spleen was almost lobulated in appearance. It could not actually be demonstrated that these were venous spaces, though it was probable, and they had the same appearance as those which Mandelbaum describes as such in his specimens. No endothelial lining was visible. The cells, which were of the Gaucher type, were large and oval and rounded, sometimes with a nucleus to one side and semilunar in shape, and sometimes with the nucleus round and more or less in the centre. The cytoplasm did not stain clearly and was often foamy; many cells also had definitely clear vacuoles, but none stained as fat with Sudan III., and there were no doubly refracting crystals in any part of the tissue. Some of the cells contained a well-formed red corpuscle and others contained dark granules. These cells were not limited to the enclosed spaces but occurred throughout the organ. There were in addition multinucleated cells like myeloplasts and an occasional eosinophil granular cell with a small round deeply staining nucleus. The Malpighian bodies were diminished in size and showed no changes in the germ centres. There was slight general increase of fibrous tissue and a few areas of hæmorrhage. The infarcted portion was of the same nature in a condition of coagulation necrosis. No abnormal cells could be found either in the liver or kidneys, and there was no fatty change in either. Some of the liver cells were foamy, but no doubly refracting material could be demonstrated. The cervical and some of the abdominal lymph glands presented similar changes to those in the spleen—i.e., there was an invasion of the follicles by large mononuclear cells with poorly staining and vacuolated protoplasm. They had no special arrangement and did not appear in the vessels. No multinuclear cells were present.

These histological findings correspond to those reported in other cases, though some observers deny phagocytosis, and here we find ingestion of red corpuscles; and in no other instance has necrosis been recorded. As in all the other specimens, except one of Mandelbaum's, the lymphoid tissue is diminished. The clinical interest of the case lies in the youthful age of the patient and in its rapid course. The onset was acute and the child lived only three weeks, having been remarkably well just before. Most cases of this disease are very chronic in course, and when it occurs in children it usually leads to progressive anæmia and emaciation and not to sudden death as in this case while the nutrition was still good. The blood picture is characteristic and differentiates from von Jaksch anæmia with its myelocytes. It differs by showing a slight leucocytosis instead of the usual leucopenia, but as there are no other signs of lymphatic proliferation it is possible that it was a terminal event, and that earlier counts might have been lower. The only other peculiarities are a liver that is not enlarged and the absence of gross hæmorrhages. Nearly all previous cases have suffered from epistaxis; in this patient there was no bleeding, but the petechiæ on the abdomen seem to have been authentic and were confirmed by several observers.

In spite of these variations from some of the cardinal signs and symptoms, the histology of the spleen, upon which, after all, the diagnosis of Gaucher's disease depends, is sufficiently true to type to make an example of this rare condition worth recording. I am indebted to Dr. W. E. Robinson for permission to do so.

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A MEETING of this Society was held at the Royal Army Medical College, Millbank, on July 11th and 12th, Lieut.-Col. H. MARRIAN PERRY, R.A.M.C., being in the chair.

J. W. MCLEOD, W. MACADAM, and B. WHEATLEY (Leeds) discussed the possible significance of hæmolytic intestinal bacteria in the causation of anæmia. Hæmolytic streptococci are rare in duodenal contents, and they thought that attention might profitably be directed to the hæmolytic hæmophilic organisms which are found in about 55 per cent. of normal throats and in some cases in the bowel.

R. CRUICKSHANK (Glasgow) described the ill-understood *Bacillus lipidus*, especially in respect of its occurrence in the stools of infants and its relation to changes in reaction.

C. H. BROWNING and R. GULBRAUSEN (Glasgow) had found that the acid-fastness of the tubercle bacillus could be readily removed by fat solvents which were acid—e.g., trichlorethylene—or neutral solvents (such as chloroform) to which minute amounts of acid had been added, leaving well-formed ghosts behind.

H. A. HAIG (Cardiff) described two cases of streptothrix infection: one beginning in the appendix and spreading over the abdomen, due to *Nocardia israeli* and successfully treated with potassium iodide; the other, caused by *Actinomyces bovis*, commencing in a rib and spreading through the thorax to the brain with involvement of the heart, which is very rare.

J. K. CLARKE (London) had experienced two cases of subacute infective endocarditis from which he has isolated by blood culture *Streptococcus mutans*, the pleomorphic organism constantly associated with the early lesions of dental caries.

H. W. CROWE (Harrogate) demonstrated the characteristic colonies of the different streptococci grown on his chocolate medium, correlated the groups thus defined with those described by other workers, and outlined a scheme of classification.

G. C. CAMERON and H. B. MAITLAND (Toronto) described the course of a transmissible rabbit encephalitis which they had met with, and C. DA FANO (London) detailed the microscopical characters of the parasite (apparently a microsporidium) with some very clear lantern slides.

J. M. BEATTIE (Liverpool) dealt in a comprehensive way with his experiments on foot-and-mouth disease in rats. The original virus came from the lymphatic glands of cattle which had been in contact with infected animals and was carried successfully from rat to rat through three passages with dorsal œdema of the feet, and vesicles on the feet and tongue as characteristic symptoms. The animals also showed a peculiar gelatinous œdema of lung which he had found in wild rats, especially in areas of Liverpool, in possible contact or communication with places where frank bovine foot-and-mouth disease had occurred. These wild rats, however, failed to infect normal experimental rats, and the opinion was generally expressed in the discussion which followed that whether the lung condition had anything to do with foot-and-mouth disease or not, it was commonly found in adult laboratory and wild rats in many places.

W. J. WILSON, J. H. DUNN, and E. M. MCV. BLAIR (Belfast), in extensive observations of the influenza epidemics of 1919, 1922, and 1924, found the serum of influenza cases to agglutinate Pfeiffer's bacillus freely and almost constantly, the reaction being manifest in the first few days of the disease and disappearing soon after defervescence. The most important point is to have an emulsion which is readily agglutinable, and this can be tested with sera preserved from times of epidemic prevalence by the addition of an equal volume of glycerine. Many controls and 25 cases of lethargic encephalitis gave negative results, except in a few cases of pulmonary tuberculosis, bronchitis, and pneumonia.

E. G. D. MURRAY (Cambridge) showed what a great influence the composition of the culture medium might have on the virulence of the meningococcus; amino-acids are important, but the results cannot be accurately predicted and have to be obtained by direct animal test in each case.

F. W. ANDREWES (London) showed how the relative quantities of specific and group agglutinins could be accurately evaluated in bacteria of the Salmonella group by graded quantitative absorption.

P. HARTLEY (London) showed that antigens and antibodies in serum could be satisfactorily preserved as dry preparations by precipitation with ether-alcohol mixtures in the cold and reconstituted by solution in water. In the system horse-serum-horse-precipitin, ether extraction of either component made little or no difference in the result, but if both were used in the extracted state no precipitate was formed. The same author also described experiments showing that radiation with ultra-violet light or the carbon arc did not enhance the capacity of guinea-pigs to produce antitoxin or rabbits to generate typhoid agglutinins, consonantly with the recent finding that the increase in the bactericidal power of the blood caused by radiation is due to influence on the phagocytes.

C. C. OKELL and E. E. BAXTER (London) described their experiments with the toxin of the Dick and Dochez streptococci used in the manner of the Schick test to measure susceptibility to scarlet fever. The toxin is neutralised with the serum of scarlet fever convalescents. No animal gives satisfactory results. Their tests showed fairly good correspondence with the clinical histories.

W. MAIR (London) suggested that it was premature to conclude that the reaction was a test for susceptibility to scarlet fever as well as a test for susceptibility to the toxin of these particular streptococci.

D. B. STEABBEN (London) found that metallic sols, gelatin, agar, peptone, and other colloids characteristically led to an immediate concentration of the blood and leucopenia followed by a leucocytosis —a response not given by crystalloid substances. The colloids had no effect on an existing antibody content, but there was some indication that they improved the response to a fresh dose of antigen.

J. MCINTOSH and L. E. H. WHITBY (London) had made further attempts to stimulate antibody production with salts of lead manganese and beryllium with completely negative results.

R. A. WEBB (Cambridge) found that an intravenous dose of meningococci given within 24 hours of another bacterial antigen resulted in sudden death with epileptiform convulsions.

A. PINEY and A. B. ROSHER (London) failed to find any relation between antibody production and lymphocyte response in the blood.

S. P. BEDSON (London) in guinea-pigs found that splenectomy led to an increase in blood platelets to about twice their normal number for about a month. During this period antiplatelet serum will reduce the number of platelets as in normal animals and will give purpura if the dose is large enough.

M. E. JOHNSTON (London) had worked out in detail the immunity to antiplatelet serum and had found no evidence of the existence of anti-antibodies.

P. HARTLEY mentioned anaphylactic experiments which led to the same conclusion.

J. F. GASKELL (Cambridge) showed that to produce lobar pneumonia in rabbits a small intratracheal dose of highly virulent pneumococci was necessary; larger doses led to general infection of the serous cavities.

J. C. G. LEDINGHAM (London) emphasised the fact that the reaction to vaccinia is essentially in the reticulo-endothelial system; it has no special affinity for epidermis.

J. A. Arkwright and S. S. Zilva (London) found that a lowering diet, qualitatively or quantitatively, much diminished the inflammatory response to diphtheria toxin and other skin irritants.

A. Leitch (London) had made many experiments by putting gall-stones, sterilised pebbles, pillules of pitch &c., into the gall-bladder of guinea-pigs; the animals mostly died in 6-12 months, and in a number of cases showed hypertrophic epithelial growth which in some instances was frankly invasive and malignant.

B. R. G. Russell (London) showed that spontaneous mouse cancer exhibited the same activity in pentose metabolism as the transplanted tumours.

A. Piney described a case of plasma-cell leukæmia, but hardly convinced the meeting that his interpretation of the nature of the cells was correct.

J. S. Dunn, A. Haworth, and N. A. Jones (Manchester) described the anatomy and histology of experimental oxalate nephritis and correlated the excretion of urine and urea and the blood-urea with the anatomical changes.

J. S. Dunn mentioned a case of pulmonary embolism with marrow tissue in a rabbit which had fractured several vertebræ.

G. H. Wilson (Birmingham) described an example of the rare pyelitis cystica in which submucous epithelial nests, arising possibly from inflammatory distortions, degenerate and leave multiple small cysts in the urinary tract.

K. Goadby (London) demonstrated the lung of a Cumberland ironstone miner who died of phthisis with an X ray picture of his chest taken five years previously.

G. L. Cheatle (London) showed a section through the whole breast in Paget's disease; G. Hadfield (Bristol) a suprarenal tumour associated with virilism; T. Lumsden (London) mammalian tissues growing in pure serum of the right reaction in vitro; T. S. P. Strangeways (Cambridge) in vitro tissue cultures showing inflammatory cytological changes; G. H. Wilson a lithopædion; G. S. Williamson (London) his method of mounting museum specimens in celloidin jars; H. M. Perry and J. A. Manifold (London) a variety of pathological specimens, and N. S. Lucas (London) osteitis deformans in a kinkajou, primary carcinoma of the liver in an oryx, leukæmia in an ocelot, and bone formation with bone-marrow in the aorta of a cockatoo from the Zoo.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held on July 2nd, Sir David Wallace, K.B.E., the President, being in the chair.

Dr. Robert Hutchison opened a discussion on

Visceroptosis.

He said that this subject was of interest not only to the anatomist, the pathologist, the neurologist, and the psycho-neurologist, but also to the physician, surgeon, and gynæcologist; yet its genesis was still little understood, and its diagnosis and treatment were still complicated by practical problems. The practitioner saw much of this condition, especially amongst women. Dr. Hutchison classified visceroptosis under two heads—viz., the so-called congenital (or "virginal") and the acquired ("maternal") types. Many reasons had been put forward from time to time to explain its greater frequency in women, but such influences as poor muscular development due to insufficient exercise, tight lacing, straining as the result of constipation, the shallow pelvis, and bad posture were in themselves not sufficient to produce drooping of the viscera or a train of symptoms. Dr. Hutchison was inclined to regard the condition more as part of a general state. These patients, who were lacking in muscular tone, showed other evidences than merely a drooping of the abdominal contents. Stiller's description of the "Morbus asthenicus" or "Habitus ptoticus" was referred to, and the speaker believed that this gave a fuller and clearer idea of the condition. Reference was also made to the work done on this subject by Sir Arthur Keith. As a physician the speaker had rarely met with the so-called virginal type amongst children, and he doubted very much if the condition was really congenital; but in this connexion he was anxious to have the opinion of a surgeon who was accustomed to perform laparotomies on children. The acquired form was more common, and he referred to the well-known factors in its production, such as weakening of the pelvic floor, stretching of the abdominal muscles, and absorption of the abdominal fat. Of bands and kinks Dr. Hutchison thought that these had a congenital origin and were not the result of stress and strain; but here again a surgical opinion would be helpful. With regard to the symptomatology, it was a question whether visceroptosis per se was capable of producing symptoms, but the improvement which was so commonly found in congenital cases, when these women became pregnant, favoured the belief that the mechanical results of dropping of the abdominal viscera could not be altogether ignored. At the same time, every practitioner was constantly meeting with cases of the acquired variety who were entirely free from symptoms. This led Dr. Hutchison to the conclusion that besides the actual dropping of the viscera there must be other factors present before symptoms were produced. Walton's view was that the presence of bands causing kinks in the gut was the direct cause of the symptoms, but division of the bands did not always give the patient relief, and Dr. Hutchison believed that functional incapacity of certain organs must also be considered as a causal factor. Visceroptotic patients frequently suffered from atony of the bowel, and deficient secretion of gastric juice, and these conditions must also be considered as a means whereby symptoms were produced. The relation of visceroptosis to neurasthenia and the neuroses was of great importance, and this immediately raised the question: Does visceroptosis cause neurasthenia or are both manifestations of the "Morbus asthenicus"? It was common knowledge that depressing emotions lowered visceral tone, and this in itself was apt to set up a vicious circle. It was really a question whether the drooping and atony of the bowel could lead to the mental depression and loss of emotional tone, as the two coexisted so frequently. These patients were often so introspective that it might be concluded that their abdominal complaints were only a cloak for some concealed mental conflict, and that in reality they were suffering from an anxiety neurosis. The physician was too apt to neglect this side of the picture. Though the diagnosis of visceroptosis was easy, the real problem at the bedside was to confirm the opinion that the symptoms were the direct result of it. There was always the possibility that the visceroptotic abdomen might also be the seat of organic disease. Visceroptosis was a great mimic, and all the known means of physical diagnosis should be employed. Finally, if any doubt existed, Dr. Hutchison recommended surgical exploration, the object in view being fully explained to the patient. From his experience of these cases the speaker did not believe that visceroptosis, per se, produced such organic conditions as gastric and duodenal ulcers, but he was inclined to think that gall-stones might follow on it. With regard to treatment, the mental factor was, perhaps, the most important, and at the same time the most difficult. He was in general agreement with the usual lines of medical treatment. The fattening cure had its ardent supporters, and there was no doubt that, combined with the usual physical treatments and abdominal supports, it often gave good results. The early detection of these cases was of importance, for they were then more responsive to treatment. He did not consider a case cured until there was an absence of symptoms for at least five years. Referring briefly to surgical treatment, Dr. Hutchison doubted very much the value of fixation operations.

Mr. JOHN FRASER said that in his experience intussusception only occurred in those children who were the subjects of visceroptosis, and this led him to the belief that the condition was congenital in origin. He referred to the embryology of the intestinal canal, and pointed out that the sympathetic nervous system was probably deficient in this variety of visceroptosis.

Prof. WILLIAM RUSSELL said that the importance of testing the functional capacity of the stomach in these cases could not be over-rated. It was essential to treat patients along these lines, and he agreed with the view that repeated pregnancies tended to produce the condition.

Sir HAROLD STILES was in complete agreement with Mr. Fraser as to the congenital origin of the condition. It was his custom to recommend proper physical training in such cases, with good results. Many cases exhibited a loss of balance between the vagus and sympathetic nerve-supply. He would only operate on the visceroptotic patient at the expressed desire of the physician, and then as a last resort.

Dr. HAIG FERGUSON, speaking as a gynæcologist, said that surgical interference was always necessary, because ligaments had been stretched, and this gave rise to ptosis, which in its turn was responsible for the marked constipation. Obstetricians had been blamed for much, but though he was against early rising after parturition, he encouraged his patients to move about gradually in bed, and by the use of graded muscular exercises loss of tone was prevented. Ptosis of the kidney was frequent in thin women after childbearing, and he had found the fattening cure particularly useful in this condition.

Prof. EDWIN BRAMWELL laid special emphasis on the psycho-neurological aspect of visceroptosis. They were admittedly difficult cases to handle, but only harm was done by those who attempted to explain away symptoms on purely anatomical evidence.

Prof. D. P. D. WILKIE said that there was some confusion of thought regarding visceroptosis in childhood. The motile cæcum, to which reference had been made, could be regarded either as a local condition which might be dealt with surgically, or as part of a general visceroptosis, and in this latter condition local surgical treatment was of no value.

Mr. W. A. COCHRANE described briefly the statics of visceroptosis, and showed how much could be done by correct posture and suitable exercises.

Dr. FREDERICK PORTER inquired whether trauma could be a factor in the production of visceroptosis.

Dr. HUTCHISON, replying, said in his experience he was convinced that visceroptosis was uncommon in children, and to the last speaker's query he would say that he did not think that trauma could be a factor in the production of this condition.

Exhibition of Clinical Cases.

Sir HAROLD STILES demonstrated two cases after operation for acoustic tumours. He described briefly the clinical findings in each case, and described his operative technique. A patient after operation for a spinal root tumour was also shown. This man had been regarded as an atypical case of progressive muscular atrophy, and at operation a vascular tumour was successfully removed. Since then there had been a steady improvement in all the symptoms and the patient was now able to walk.

Mr. J. W. STRUTHERS showed a case of multiple exostoses. Keith had suggested the name diaphyseal aclasis for this condition. Emphasising the importance of a thorough investigation of all cases of hæmaturia, however transient, Mr. Struthers showed two patients after removal of malignant tumours of the kidney, in whom the earliest sign had been the passage of blood in the urine, and this at the first onset had not been fully investigated. He also showed specimens from a case in which a patient suffered from fracture of the femur, paraplegia, &c., due to secondary deposits from a small "latent" malignant tumour.

Reviews and Notices of Books.

CRIME AND INSANITY.

By W. C. SULLIVAN, M.D., Medical Superintendent, Broadmoor Criminal Lunatic Asylum. London: Edward Arnold and Co. 1924. Pp. 259. 12*s.* 6*d.*

Dr. Sullivan follows closely the principle that the only method of investigating the relation of psychopathology to crime is the clinical examination of the *individual criminal*, and he arranges his ample material in accordance with the form of the mental disorder present. The modes of reaction peculiar to alcholism, dementia præcox, epilepsy and systematised delusional insanity are shown by case-histories not only of clinical but of psychological interest. The sufferer from dementia præcox, for example, may recognise the homicidal impulse as independent of and irrelevant to the rest of his conscious personality, and the lucid accounts given by such patients, often without attempt at excuse or rationalisation, offer a fascinating problem in psychology and give point to a later remark that the McNaghten rules would make most insane criminals fully responsible. The author affirms that whilst alcoholism is the most important of the individual morbid factors of crime, yet it is of very small account in the insanity of the asylum. The fluctuations of psychiatric doctrine now place in the dementia præcox group most of the cases formerly described as paranoia; yet paranoia has exerted an unfortunate influence on legal conceptions of morbid psychology, which attribute a grossly exaggerated importance to delusion and ignore almost entirely the primary and dominant influence of morbid impulse. It is noteworthy that, although epilepsy often serves where a defence of insanity would be otherwise feeble, the incidence of epilepsy is the same in the criminal lunatic population as in the inmates of ordinary asylums.

In the excellent chapter on transitory mental disorders attention is paid to the genuineness of the amnesia so often claimed, but the possibility of restoring the lost memories is not considered, and the generalisation that the most emotional impressions in neurotic dream states are more likely to be retained (perhaps one should say "*recalled*") does not agree with the findings in the numerous amnesias after "shell-shock." The use of statistics of criminal lunacy to confirm the view that the psychopathological factor is of little importance in acquisitive crime unduly narrows the meaning of "psychopathological" and excludes those mental disturbances which lead to minor delinquencies. It is plain, however, that the cases of this nature described by Dr. Hamblin Smith in his "Psychology of the Criminal" are not only in a legal category different from that in which Dr. Sullivan's are placed, but differ also in being accessible to treatment by analysis. The legal conception of insanity, therefore, is correlated with some fundamental psychological condition. A hint of the nature of this condition is supplied by Dr. Sullivan when he notes a relation between the behaviour of the dementia præcox patient and the Freudian theory of the Œdipus complex. It seems as if these patients live in the world of unconscious fantasy, whilst the merely psycho-neurotic—like Dr. Hamblin Smith's subjects—are influenced by unconscious fantasy but are able to judge it by reality standards when it is revealed to them by analysis.

The study of clinical material leads of course to the question of responsibility, and Dr. Sullivan claims for psychiatry only the right to ask how far the legal criteria of responsibility are adapted to secure the ends which the law has in establishing them. The question reveals a tangle of inconsistencies created by our inheritance of the belief that disorder of intellect is the sole criterion of insanity. The difficulties of the McNaghten test have been circumvented by evasion or distortion of the legal formula, and the result of the test itself may be abrogated by the statutory inquiry prescribed in cases where the Secretary of State has reason to believe that a prisoner under sentence of death is insane. Following upon the case of R. v. True, the Atkin Committee recommended that irresistible impulse should exclude responsibility, but Dr. Sullivan shows that even with this addition to the test the ends of the law are not attained. The content of the delusion is still a criterion, and the lunatic is still responsible who murders a supposed persecutor under the delusion that his fancied enemy is reading his thoughts. The author's remedy for this curious product of legal psychology and for other difficulties is to replace *ex parte* evidence, given in the form of artificial and fragmentary replies to more or less relevant questions, by a full and connected statement by impartial witnesses. This would reach at the outset the result now attained by the tedious stages of trial, appeal, and revision by the Secretary of State.

Dr. Sullivan writes with well-earned authority and the book is an important and valuable one. It should receive the attention of all to whom an understanding of the subject is necessary.

THE NERVOUS CHILD.

Third Edition. By H. C. CAMERON, M.D., F.R.C.P., Physician in Charge of Children's Department, Guy's Hospital. London: Humphrey Milford, Oxford University Press. 1924. Pp. 233. 7*s.* 6*d.*

THE two previous editions of this book have already won for it an established place in the literature of children's diseases. The third edition, which now appears as a further testimony to the popularity of the work, contains relatively little new matter. Additions have been made to the chapter dealing with various signs of nervousness. The chief alterations are found in the chapter on Nervousness and Physique, which has been enlarged and enriched by a series of excellent photographs illustrating the types described, among others, the type to which Dr. Cameron has given the name of "status catarrhalis." It is not altogether easy to understand the author's reluctance to class these cases as rickets because of the inconstancy of bony changes; moreover, it seems to be of some importance that both parents and medical men should recognise that the factors in the production of this type are those of rickets—nutritional and environmental—rather than hereditary, as in so many other types of nervous children.

This book contains a large amount of material for which place cannot be found in a general textbook, and will continue to be of the greatest value in providing the practitioner with a practical scheme for the regulation of the child's environment.

AN INTERNATIONAL YEAR-BOOK OF CHILD CARE AND PROTECTION.

Compiled from Official Sources by EDWARD FULLER. London: Longmans, Green and Co. 1924. Pp. 448. 7*s.* 6*d.*

MR. FULLER, who is editor of the *World's Children*, has compiled this year-book from official sources with the intention of providing as complete a record as possible of State and voluntary effort for the welfare of the child, including education, care of the delinquent and destitute, and conditions of juvenile employment throughout the world. The year-book is published for the Save the Children Fund and contains an introduction by Mr. Percy Alden, M.P., chairman of this fund and hon. secretary of the British Institute of Social Service. An attempt has been made to deal with all the countries scheduled on a uniform plan, although this aim has been impeded by the fact that in a number of countries the term "child welfare" is so construed as to include the care of destitute children, undertaken here by the Poor-law [illegible] national agreements and laws relating to child life is included, and the Declaration of Geneva. Inequality is inevitable in the first appearance of a new and comprehensive work of this kind, and Mr. Fuller would welcome (at 26, Gordon-street, London, W.C.) criticisms and suggestions from readers for a later edition. The attempted compilation of names to form "An International Who's Who" is not feasible; such a list would be of value for reference at the offices of the Fund, but glaring errors of omission or commission can hardly be avoided. The year-book will be used wherever the particular interests of children come up for consideration.

THE PHYSIOLOGY OF COLOUR RESPONSE.

The Pigmentary Effector System. By L. T. HOGBEN. Edinburgh: Oliver and Boyd. 1924. With 17 figures in the text. Pp. 152. 10*s.* 6*d.*

BY the "pigmentary effector system" the author means the apparatus by which animals such as chameleons, frogs, and fishes change their colours, which they do mostly in relation to changes in the colour and illumination of their surroundings. The change is generally brought about by movements of the pigment granules which are contained in special branched cells in the skin, though it is not certain whether the whole cell contracts or expands or whether the granules move inside the cell. An ordinary frog in dry white warm surroundings in a bright light is quite pale; the pigment granules are collected together in small isolated masses. In a wet, black, cold, and dusky environment the same animal in about a couple of days becomes black owing to the dispersion of the granules throughout the cells which contain them. The author, with Mr. F. R. Winton, has shown that the reaction is in this case under the control of the pituitary. The middle and posterior lobes contain a substance which induces expansion of the pigment and darkening of the skin; the reaction is of such delicacy that it would seem of likely utility in the pharmacological assay of pituitary extracts. Frogs from which the pituitary has been removed become and remain permanently pale with contracted pigment; they may be darkened by the injection of pituitary extract. In reptiles the responses are rather different and adrenalin has at least a considerable share in bringing them about. In fishes the nervous system plays an important part. In crustacea the pigment-bearing cells are multicellular organs with, in some cases, a variety of pigments which behave differently under different circumstances.

We have here a most interesting account of a phenomenon which in one form or another is widespread. The book is the first of a series of biological monographs and manuals under the editorship of Dr. F. A. E. Crew, of Edinburgh, and Mr. D. W. Cutler, of Rothamsted, and if the succeeding volumes reach the same standard they will be useful additions to scientific literature. The publishers might reconsider the format; the type and pages are too big.

INCOMPATIBILITY IN PRESCRIPTIONS, AND HOW TO AVOID IT.

By THOS. STEPHENSON, D.Sc. Edinburgh: *Prescriber* Office. 1924. Pp. 32. 1*s.* 6*d.*

THIS pamphlet is a reprint of articles contributed to *The Prescriber* by its editor, together with some additional matter.

A definition of incompatibility is quoted as "any unintentional change which notably interferes with the elegance, usefulness, or safety of a prescription," and such changes are grouped into three classes: (1) chemical, (2) physical or pharmaceutical, and (3) therapeutic, though both chemical and physical changes might be described as pharmaceutical. Cases of chemical incompatibility are fully and systematically described as occurring when: (*a*) an insoluble compound is precipitated; (*b*) gas is evolved; (*c*) an acid and an alkaline substance are mixed; (*d*) one of the ingredients is decomposed; (*e*) an alkaloid is precipitated ; (*f*) an undesirable compound is formed. Each section is discussed in detail, and all likely cases of incompatibility are indicated. Perhaps the most noteworthy feature is the inclusion of a sub-section dealing with explosive reactions. This should be of great value to all physicians and practitioners, many prescriptions being quoted of which the extremely dangerous nature might easily be overlooked. Potassium chlorate and other oxidising agents are the most likely causes of trouble in this respect. Although nitroglycerine is safe in 1 per cent. alcoholic solution, the latter on dilution deposits the nitroglycerine as an oil, which is very highly explosive. The safest method of prescribing nitroglycerine, therefore, is in chocolate tablets. Cases of physical incompatibility are classified under the headings of: (*a*) insolubility ; (*b*) immiscibility ; (*c*) undesirable colour change ; (*d*) unsuitable consistence or excessive bulk ; (*e*) molecular change, as formation of liquid on mixing solids. A brief section deals with therapeutic incompatibility, and a very useful table of incompatibilities of all the usual drugs is given. An adequate index forms a valuable addition too often omitted from short works of this type.

The statement that acetyl-salicylic acid (aspirin) decomposes potassium iodide with liberation of iodine requires qualification, as this reaction cannot take place if both substances are reasonably pure. On p. 21 we find: "Many of the water-soluble metallic salts, and especially those that are deliquescent, are insoluble in alcohol, and the addition of any spiritous preparation, such as a tincture, often throws such salts out of solution." This is quite true, except for the words "those that are deliquescent," as actually it is the non-deliquescent salts which are least soluble in alcohol. The author states, with a certain amount of scepticism, that "sodium bicarbonate is also said to convert calomel into corrosive sublimate, but no toxic effects appear to have been observed from such a combination." The scepticism is certainly justified.

The pamphlet gives in a convenient form and at a low price information which at any time may be of the greatest value. The subject is of importance to those who prescribe and those who dispense, and it is possibly of even greater moment to the former, as they are less likely to be made aware of the incompatibility by seeing its results themselves. This practical little work should prevent them from falling into any of the pitfalls.

Handbuch der Biologischen Arbeitsmethoden.

Edited by Prof. Dr. Emil Abderhalden. Berlin: Urban und Schwarzenberg. Section 112, Verdauungsapparat. Swiss Fr.19·9. Section 122, Untersuchungen an einzelligen Lebewesen. Swiss Fr.7·5. Section 125, Immunitätsforschung. Swiss Fr.4·5. Section 126, Untersuchungen des Harns. Swiss Fr.4·8. Section 127, Nahrungs- und Genussmitteluntersuchungen. Swiss Fr.11·4. Section 128, Die Methoden der Medizinescher Statistik. Swiss Fr.7·8. Section 129, Funktionen Bestemmeter Organe. Swiss Fr.7·5.

Of the six sections of this admirable system recently published, Section 112 deals with the investigation of saliva, fæces, intestinal gases, and gastric contents. Minute details are given with regard to academic investigations. The more modern clinical investigations are less well covered ; thus there is in the section dealing with fæces no reference to the microscopic appearance. Again, in the description of the methods of examining gastric contents modern work on the fractional methods of investigation is not mentioned. Section 122 contains detailed accounts of the various methods of investigating unicellular organisms of the plant and animal kingdom and a good account of staining and microscopic methods is given. The part dealing with microscopic research is full, and contains descriptions of many useful techniques. But it is for Section 125 of the series that the handbook is best known to the pathologist and bacteriologist. The volume under review contains an account of the methods of demonstrating the Pfeiffer phenomena and of the preparation of bactericidal sera, and also an account of the von Pirquet reaction ; its contents are of great practical value to laboratory workers in pathology. Section 126 is devoted to the chemistry of various amine bodies in urine and forms a complete and exhaustive treatise on the subject. Although outside the sphere of ordinary biochemical work, this volume would prove of the greatest value to any person working at this particular branch. Section 127 contains descriptions of methods of investigating alcoholic beverages and tobacco. The descriptions are of a purely technical nature and, as elsewhere, the treatment of the subject is exhaustive. Section 128 opens the part of the work dealing with medical statistics. It commences with a general account of the subject and then proceeds to describe the various methods used in the German State Departments for working out the various statistical records such as death-rates and birth-rates. It is interesting to contrast the German methods and findings with those in this country. Section 129 is of particular interest since it describes the methods of investigating, by animal experiments, various organs such as the pituitary and suprarenals. Detailed accounts are given for the methods of extirpation of these organs and an excellent series of photographs demonstrating the results in various animals. The accounts, therefore, are likely to interest physiologists. In no other single volume is it possible to obtain descriptions of these operations, and sound pharmacological information is also provided. Altogether, it is difficult to praise too highly the industry and sense of balance shown in the compiling of this great work.

Précis de Chimie Physique.

By H. Vigneron. Paris: Masson et Cie. 1924. Pp. 403. Fr.30.

This little volume deals with physiological chemistry in a very efficient manner and the mathematics are kept within such bounds as could be understood by most readers. Very good accounts are given of Langmuir's theories and also of the application of the Le Chatelier theorem. The section dealing with the theory of ions, and particularly hydrogen-ion concentration, is disappointing, and in parts almost unintelligible. On the whole, however, the explanations are clear and the line drawings are particularly useful.

Anatomy of the Teeth.

The Microscopic and General Anatomy of the Teeth, Human and Comparative. Second edition. By J. Howard Mummery, C.B.E., F.R.C.S., L.D.S. London: Humphrey Milford, Oxford University Press. 1924. Pp. 618. 35*s.*

So much new matter appears in this new edition of Mr. Mummery's well-known book that it must be considered as a fresh publication. The book is nearly doubled in size by the addition of a section dealing with the macroscopic human and comparative anatomy of the teeth. Thus the whole syllabus in dental anatomy required for the L.D.S. and other dental degrees is comprised in one volume. This will undoubtedly prove a great convenience to the student who hitherto, if he has wished to use this book, has been compelled to purchase in addition some other book dealing with comparative dental anatomy.

The first part, covering the microscopic anatomy of the teeth, is not very different from this section of the work as it appeared in the first edition. The chapters on calcification have been rearranged and should help the student to understand better this very difficult subject. An account of the author's discovery of vaso-motor fibres to the vessels of the pulp is included. The second part of the book commences with an admirable description of the anatomy of the human teeth. The tendency is for examiners to lay a greater stress on a knowledge of the teeth of man. They rightly expect the student to know them in detail, for without such knowledge the practice of dentistry must be empirical. The illustrations to this section are extremely good; indeed, they are the best we have ever seen. The various theories of tooth development are described in considerable detail, and include Bolk's dimeric theory. Mr. Mummery has wisely not attempted to describe the dentition of the vertebrates in detail. Such knowledge is not necessary to a dental student. The inclusion of this subject in the syllabus is designed to illustrate the process of evolution by reference to the teeth, which exemplify the nature of adaptive modification almost better than any other structure. A broad sketch which emphasises those aspects of evolutionary significance but omits minor details of less importance is just what is required in a book of this kind, and Mr. Mummery supplies it. The account of the evolution of the dentitions of the horse and elephant, for instance, is excellent. The illustrations are produced on plates printed on art paper instead of being interspersed in the text. They are all original drawings and are extremely good. The book is singularly free from errors. "Thalycine" should, of course, be thylacine. A full index curiously enough omits any reference to the dental pulp.

A special word of praise is due to the publishers for the way in which they have produced the book.

THE DEVELOPMENT OF THE HUMAN BODY.

Seventh edition. By J. PLAYFAIR MCMURRICH, Professor of Anatomy in the University of Toronto. London: Henry Kimpton. 1924. Pp. 506. 18s.

THIS book has gained a prominent place among works on human development by reason of its clear expositions and of the large amount of information contained in it. The present edition, although it has been altered in some ways, shows no diminution in these excellent qualities, and we observe a number of new illustrations. There are a few slips in the editing of the book which might have been avoided—for example, the reference on p. 488 to Fig. 285 ought to be 288, and in Fig. 186 the subject discloses an affection for standing on its head which we imagine is really not intended by the writer. In spite of the fact that in some details the accounts of development are not quite those adopted in English text-books—possibly owing to the author's decided preference for German work—the seventh edition of Prof. McMurrich's little book can be heartily recommended to those who wish to obtain a comprehensible and fairly comprehensive view of the matter of which it treats.

RESEARCH IN DAIRYING:

OPENING OF THE NATIONAL INSTITUTE.

ON July 19th the formal opening took place of the National Institute for Research in Dairying at Shinfield, near Reading, when a large company representative of those interested in dairy problems were entertained by Lord Elveden, chairman of the governing board. When a scheme of agricultural research was formulated under the Development and Road Improvement Fund Act, 1909, by the Board of Agriculture, Reading was chosen as the centre for dairy investigations, and in 1912 the Research Institute in Dairying was established at University College, Reading. At the outset the Institute had to depend for its material on supplies from the College farm and the British Dairy Institute of the College, but in October, 1920, the Shinfield Manor Estate of about 350 acres was secured, and an experimental farm was started with the farm buildings then in existence. In June of the following year, by means of a grant from the Development Commissioners and private donations, the purchase of the estate was completed and the general control of the Institute delegated to a governing board, on which, in addition to the Ministry of Agriculture and the Ministry of Health, several other important agricultural interests were represented. At this time the Institute adopted the title it now bears. Shinfield Manor House has been transformed into a series of laboratories and offices, and additional buildings have been erected at a cost of about £30,000. Towards this sum a grant of £13,000 was made by the Development Commissioners, and the balance is being raised by public appeal.

The Laboratories.

The new laboratories contain a chemical department where work on accessory food factors, as, for example, the source of vitamin A in butter, and investigations into the nature and causes of abnormal milks, and the effect of heat on milk are carried out. In the bacteriological department, under the direction of Dr. R. Stenhouse Williams, investigations are at present being undertaken into such problems as the relative efficiency of steam and dairy disinfectants in sterilising dairy utensils, and the importance of *B. coli* content of milk and its effect on the keeping quality of the milk. The additional new buildings include a dairy, in which an ammonia cold-storage plant has been installed. On the dairy farm a herd of from 40 to 50 cows is maintained, and the new buildings in connexion with this branch of the Institute's activities comprise food stores, granaries, and cowsheds. The library contains over 2000 books and receives bulletins from various colleges and experimental stations.

The Importance of Research Work.

The opening ceremony was performed by Lady Elveden, and lunch was provided in one of the new cowsheds. The toast of the Ministry of Agriculture and the Development Commissioners was submitted by Mr. W. M. Childs, Principal of the University College, Reading. In reply, Mr. J. F. Blackshaw said that the Ministry and the Commissioners had gladly done all they could to develop the work of the Institute. Generous financial assistance had been rendered by Lord Elveden and funds had also been raised from the industry itself, though in that connexion more difficulty had been experienced than ought to have been the case. Research was of the highest importance to dairy farming if they were successfully to meet the competition of other countries who were engaged in a genuine effort to raise the standard of the industry, both to benefit their own people and to gain a foothold in the British market. Lord Elveden, who presided, in proposing "Prosperity to the Institute," spoke of the future of research in dairying. Around the Institute, he said, there had sprung up an industry which was almost unique—an industry engaged in the supply of wholesome milk from animals that had passed the tuberculin test, which was being sold at prices within the means of even the poorest members of the community. By scientific feeding of the cows it had been possible to produce milk at *2d.* or *3d.* a gallon cheaper than many farmers could produce it, and that result suggested most valuable possibilities. Milk production carried the largest amount of labour on the land, and therefore such research as was being carried out at the Institute opened a vista of increasing national prosperity to the countryside. It was encouraging to note that the principles laid down by the Institute had been adopted by the Government of New Zealand, and that the Dutch, too, were proposing to apply them. All over the country farmers in increasing numbers were now seeking to apply scientific methods in their efforts to produce better cattle, cleaner milk, better cheese, and better butter. Mr. E. Matthews (vice-chairman of the board) and Mr. Holt Thomas replied. At the close of the proceedings it was announced that as the result of an appeal for further donations to the Institute sums amounting to £1070 had been subscribed, which sum Lord Elveden intimated he would double.

THE LANCET.

LONDON: SATURDAY, JULY 26, 1924.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

The annual meeting of the British Medical Association was held this year for the first time in a great industrial city of the north containing no medical school of its own, although Bradford medical institutions have excited the keenest interest far beyond its borders. The Lord Mayor of Bradford, in welcoming the Association, asked the members to study the experiments in municipal medicine in which the city took great pride, and full use was made of this invitation, with the result that the municipal hospital and municipal clinics of Bradford are now familiar to many who only had known of them previously as subjects of controversy. The lavish hospitality offered by individual citizens—for hotel accommodation is strictly limited in such a purely business community—also brought about the mutual knowledge needed for sympathetic understanding. It is probable, indeed, that the visit of the Association to Bradford has finally assured the continuance of the friendly relations growing up between the official representatives of medical policy and a city which was honestly desirous of running its socio-medical institutions in its own way. Although without a medical school, Bradford is not without academic distinction in medicine, as Mr. Basil Hall, President-elect of the Association, was at pains to point out in his inaugural address. It is natural that wool-sorters' disease should have been recognised in a city where wool is the chief means of livelihood, and work is proceeding which should result in the total prevention of anthrax without damage to the commercial value of the wool.

The Representative Body, whose labours we report in part on another page, was inclined to exploit still further its expansive mood of last year. The time is approaching when the new home of the Association in the neighbourhood of Tavistock-square will be ready for occupation, and will provide accommodation for the ever-expanding work of the Association, as well as a conference hall with great decorative promise. The membership of the Association now exceeds 27,000, a high-water mark in absolute numbers, although the actual ratio to the number of names on the Medical Register is not yet quite what it was in 1912, and by means of good staff work a large percentage—in some centres almost all—of the newly qualified men and women are being brought into the fold. Consideration of these facts made the Representative Body ambitious to supply all the material needs of its membership. The organisation of benevolent funds and of individual—as distinguished from collective—defence has hitherto been left to other agencies, the devotion and efficiency of which is not questioned. The Representative Body was invited in both instances to refer it to the Council to consider whether these things could not be done and done better by the Association itself, for the Association could no longer afford to remain outside concerns of such vital interest to its members. In the case of benevolent funds the decision was actually taken. The reference in the case of individual defence was only defeated by a very small margin, and feeling in this direction is evidently growing so rapidly that the step is well-nigh a certainty next year. The existing defence societies, which have had a very long start in regard both to time and experience, would hardly find themselves in so good a position as the branch secretaries of the Association for approaching the newly qualified men and women, and for this reason, if for no other, may not remain unwilling to coöperate.

It is now 21 years since the new constitution of the Association came into force, and apart from the activities to which allusion has been made the occasion was thought to demand some formal recognition. The chairman of the Representative Body is accordingly to be provided with some appropriate badge of office. This badge, when it has been designed and produced, will be too late to decorate the retiring chairman, Dr. Wallace Henry, whose services during a number of difficult years have been signal. He will, however, be succeeded in the chair by Dr. H. B. Brackenbury, for so long chairman of the Insurance Acts Committee, Dr. C. O. Hawthorne being elected at the same time as deputy-chairman. The Association is happy in the number of public-spirited men among its members willing to give time and ability in its service.

◆

TEMPERANCE LEGISLATION.

The Liquor (Popular Control) Bill, which was recently introduced in the House of Lords by the Bishop of Oxford, was rejected by a substantial majority on the motion for its second reading. We do not find it possible to regret this result, for, though the Bill may have been good in parts—and we think it was—its main proposals seem to have been unwisely conceived, if only because their practical effect, if the Bill had become law, would probably have been anything but beneficial to the cause of temperance. The debate on the second reading was so largely concerned either with points of detail, or with the repetition of the rhetoric traditional amongst controversialists on either side of an intricate question, that the fundamental principles of the Bill were inadequately discussed save in two or three speeches, of which that of Lord Dawson was specially noteworthy. While it is right that discussion of a social reform so intimately associated with medicine should receive its most weighty contribution from the only medical man among those taking part in the debate, it is a matter for regret that other speakers, enjoying great opportunities for forming opinions, should have confined themselves to detailed criticism. The provisions of the Bill and the speeches delivered in its support certainly indicated a confusion of ideas regarding the scope and object of temperance legislation—a confusion which might perhaps have been dissipated, to the great advantage of the cause of social reform, had the proposals been more carefully scrutinised, and especially had the standpoint taken allowed of a wider range of inspection. What is remarkable about the Bishop of Oxford's Bill is not any quality of freshness or originality in its proposals—for the principle of local option which it sought to establish is a very old, and hardly a firm, plank of the extreme temperance platform, but rather the fact that such proposals should be seriously advanced as applicable to the liquor problem in this country at the present time. To advocate the policy of local option as a method of abating the evils of alcoholism in this country to-day seems to us to indicate a singular indifference alike to the nature and effect of that policy and to the facts of recent experience in regard to the whole temperance question.

Local option, to have any *raison d'être* at all, presupposes the existence of local diversities of opinion, so that the effect of its adoption would be a partial prohibition, resulting in an irregular patchwork of areas where the sale of alcohol is illegal and of areas where it is permitted, whether under private or public ownership. Now the criticisms of prohibition as an unwarranted extension of legal control over individual liberty, whatever be the value of such criticisms, apply equally to prohibition in large and in small areas. And—which is of more practical importance—the mischievous results which are apt to follow from the legal repression of the sale of alcoholic beverages will certainly not be less, and may be greater, when prohibition is established in a patch fashion over small areas than when it is extended to an entire country. This was a matter of common experience when local option was in force in the United States, and the difficulty of dealing with these evils was, in fact, one of the stock arguments for the wider policy of national prohibition. That similar results would follow from the adoption of this policy in England is foreshadowed by what is found in areas where Sunday closing is in force; and the mischief in this country would be the more deplorable because it would mean the undoing of the most effective and rational scheme which has yet been evolved in the history of temperance legislation. Why, in the discussion of the Bishop of OXFORD's Bill, were the speakers on either side coy in their references to the Licensing Act of 1920, which embodied the essential features of the system of physiological control of the liquor trade, devised by Lord D'ABERNON and enforced by the Central Control Board during the war? Possibly a policy which rejects alike the attitude of laissez-faire in face of a grave and remediable social evil and that of fanatical repression on the score of possible abuses, can hardly be expected to arouse enthusiasm in the clash of contending and equally intemperate opinions. However that may be, the perusal of the debate in the House of Lords certainly left the impression on those medical men who attempt to look at things as they are that the speakers failed to recognise the extent of the change, we may say revolution, which has been brought about in the national alcoholic consumption through the application of the policy of control. Still less does it seem to have been perceived that this policy of control, which has wrought so salutary a change, is wholly irreconcilable with all such attenuated forms of prohibition as local option, Sunday closing, and the like. The system of physiological control was deliberately designed with a view to checking excessive drinking while allowing full opportunity for the safe and temperate use of alcoholic beverages. In pursuit of that aim, the restrictions on the hours and conditions of sale of alcoholic liquor were *arranged so as to avoid any risk of providing* an adequate motive for organising an illicit traffic in [illegible] The practical disappearance of delirium [illegible] rom the wards of the Poor-law infirmaries, [illegible] ous fall in the registered death-rate from [illegible] and from cirrhosis of the liver, the large [illegible] ction in the amount of grave alcoholic crime—all these facts are sufficient proof that the great decrease of public drunkenness under control was not associated with any development of illicit traffic in drink. For it is, of course, the rule, as a priori considerations would suggest and as the experience of America amply proves, that a clandestine trade in liquor is always a trade in concentrated and impure spirits, which are apt to have a specially injurious effect on health, so that any extension of secret distilling or shebeening promptly becomes revealed in the statistical movement of alcoholic disease and mortality. The absence of any such reaction since the enforcement of the policy of control shows quite clearly that the restrictions on the legal hours of sale have always been within the limits of safety; the close times have never been long enough to make systematic violation of the law worth while. A trivial amount of shebeening no doubt exists for the most part in areas under the corrupting influence of Sunday closing, but it is certainly not more frequent than it was before the days of control. And Sunday closing has also to be related to another manifestation of abnormal intemperance—namely, the use of methylated spirits as a substitute for the ordinary alcoholic beverages. It is pointed out in Licensing Statistics for 1922 that, while methylated spirit drinking accounts for only about 0·7 per cent. of the total number of convictions for drunkenness in England and Wales, the proportion of such cases is as high as 21 per cent. in Cardiff, 14 per cent. in Newport (Mon.), and 7 per cent. in Swansea—the chief centres of population which are affected by the partial prohibition of Sunday closing. Such facts as these would seem to suggest that the mixture of temperance policies may be attended with as undesirable results as have been popularly ascribed to the mixing of liquors, and that at all events the advantages which may be obtained by reasonable methods of control are likely to be considerably neutralised when these methods are combined with a partial application of the opposite principle of prohibition.

Within the last ten years the world has seen two great experiments in the legislative treatment of the social problem of alcoholism, and the results are now sufficiently clear to justify a fairly positive opinion as to the respective merits of the two policies which have been tried. In the United States of America it has been sought to remedy the evils of intemperance by absolutely prohibiting the production and sale of alcoholic beverages, by penalising all consumption of alcohol whether moderate or excessive. In this country, on the other hand, the legislature has recognised a distinction between use and abuse, and has limited its interference with the drinking habits of the people to such restrictive measures as will minimise the risk of casual or habitual intemperance. It is possible, of course, that the special conditions of the liquor problem in the United States may be such that the beneficial results of prohibition outweigh its very obvious disadvantages; that is a matter on which foreign opinion might seem impertinent. But it is quite clear that the operation of the system in America has shown that, if applied in this country, its influence for good would be far less efficacious than that of the existing system of control, while its reaction on the health and morale of the population, by its effect in promoting illicit alcoholism and organised defiance of the law, would be highly pernicious. The policy of prohibition, as Lord DAWSON rightly insisted, cannot claim the support of medical science, which condemns the abuse but not the use of alcoholic beverages. If, indeed, the use inevitably entailed the abuse, and if prohibition could really do away with both together, the practical gain might make the policy acceptable on grounds of expediency. But in fact, as the experience of control in this country has clearly shown, it is quite practicable by intelligent regulation to retain the dietetic and convivial consumption of alcohol while eliminating in a very large measure the dangers of excess; and the experience of America has proved to demonstration that prohibition, though it may make moderate drinking illegal, is quite ineffectual in making excessive drinking difficult. With these object-lessons which recent history has brought out so clearly, it is much to be regretted that the zeal of temperance reformers in this country should be wasted in the advocacy of an attenuated type of prohibition, which would not only be futile in itself, but would tend to weaken and pervert the operation of the really effectual policy of control. This latter policy, of course, is still in a stage of imperfect development, and its elaboration and extension will provide ample scope for reforming activity in the future. It may well be, for instance, that its more thorough application will require the transfer of the liquor trade to public ownership. It should help to make clear the true path of progress if we recognise at the outset that local option and other manifestations of the principle of prohibition can have no place in any such programme of reform. Local option is in theory and in effect the negation of the rational and successful system of physiological control.

◆

ARTIFICIAL PNEUMOTHORAX.

AN interesting stage in the development of any new method of treatment is that in which, after its value has been established, the indications and contra-indications for its employment, and the limitations of its usefulness, are being investigated. Artificial pneumothorax was first employed in the treatment of pulmonary tuberculosis in this country in 1910, over 20 years after its introduction in Italy by FORLANINI. It is now recognised by nearly all workers in tuberculosis here as a valuable addition to treatment, not infrequently helping cases in which the ordinary methods of treatment fail, and restoring to working capacity many patients who otherwise would be condemned at best to chronic invalidism and sooner or later to complete breakdown. The value of artificial pneumothorax is not, however, as widely recognised by the profession at large in this country as its importance deserves; the method is too often regarded as a desperate resort in advanced cases.

We publish this week two interesting papers; the first is by Dr. L. S. T. BURRELL, giving the results of his first 250 cases up to date, and extending and amplifying the information given in the valuable report [1] presented to the Medical Research Council in 1922 by Dr. A. S. MACNALTY and himself; the second paper is by Dr. R. C. WINGFIELD and Dr. G. SELBY WILSON, which forms an admirable complement. This paper deals with the conduct of the cases in which artificial pneumothorax has been employed, correlating certain of the clinical features with the ultimate results obtained. Dr. BURRELL's results show, what might naturally be expected, that the best results are obtained in patients with moderate resistance to the disease, in whom the condition is unilateral. He finds that in bilateral cases although the immediate results of artificial pneumothorax on the more affected side may be good, relapse usually occurs and the late results are unsatisfactory, though life may be considerably prolonged. In the report to the Medical Research Council, Dr. BURRELL gave categorically his views as to the merits and demerits of this form of treatment. In the present paper he emphasises his opinion that early diagnosis in a great majority of cases enables arrest to be achieved by ordinary methods, and that artificial pneumothorax should be considered not as a routine treatment, but as a safe method of resting the diseased part of the lung where ordinary methods fail, so that while it should not be used for early cases, its consideration should not be too long deferred in cases which do not respond to other methods. He discusses the dangers and the complications and shows that they are not serious enough to weigh against the undoubted benefits that it is capable of conferring upon cases properly selected.

The paper by Dr. WINGFIELD and Dr. WILSON deals with 75 cases treated at Frimley Sanatorium, in 60 of which the induction of the pneumothorax was carried out at the Brompton Hospital. They deal specially with the criteria for estimating the effect of this form of treatment, and do not discuss its value or even the details of its application, such as the spacing of the refills or their amounts. Many observations of great interest emerge from the analysis of their cases. Thus the length of time between the induction and the commencement of exercise has varied from 6 days to 285, with an average of 106. These figures should warn us against expecting dramatic results from the treatment. After defining relapse as any condition, whether accompanied by pyrexia or not, necessitating stopping exercise and being put on "rest" for four days or more, the authors find that the longer such a relapse, the worse the ultimate prognosis, and the earlier it occurs after exercise has been started, the less likelihood of an eventual good result. On the other hand, a relapse occurring for the first time when the patient has reached a high grade of exercise is of little importance. They find that better results are obtained in those with a complete collapse than in those in whom partial collapse only has been obtained, but in the absence of details as to the degree of disease before induction, they deprecate the use of their figures as an argument in favour of dividing adhesions. Their views on the value of pneumothorax treatment in bilateral disease are in substantial agreement with those of Dr. BURRELL. They find that an irregular or a periodic temperature in men is an unfavourable indication. One of the great benefits of this form of treatment is the cessation of cough and sputum, or, if sputum persists, the disappearance from it of tubercle bacilli. Dr. WINGFIELD and Dr. WILSON's figures show that when the bacilli persist in the sputum in spite of the treatment the outlook is very unfavourable. As with other modes of treatment gain in weight is a valuable index of the beneficial effect of this treatment. Early loss of weight is of grave import and should lead to a reconsideration of the treatment as a whole. A complication discussed in both papers is that of pleural effusion occurring in the course of artificial pneumothorax. Dr. WINGFIELD and Dr. WILSON maintain that where the effusion is clear and non-purulent it has no influence on the ultimate result, an opinion in which Dr. BURRELL concurs, except that he finds that in cases occurring in association with bilateral disease the outlook is less good and that there is a tendency for the effusion to become purulent. It is allowed in both papers that a purulent effusion is a grave occurrence. Perhaps the most striking result is that in Dr. WINGFIELD and Dr. WILSON's cases, which were an unselected, consecutive series, including a proportion of the late stage or "last resort" types of case, no less than 49 per cent. were restored to working capacity. It is noteworthy that these results were obtained in a sanatorium, and it serves to emphasise Dr. BURRELL's opinion to the effect that artificial pneumothorax is not to be regarded as a cure for pulmonary tuberculosis, but as a safe method of ensuring rest of the diseased part of the lung, to be used in conjunction with other methods of treatment. This seems to us to be the true perspective, and used with due discrimination the induction of artificial pneumothorax will give even better results than at present. It must be emphasised, however, that the selection of cases should be most carefully made, and here X ray examination is, we hold, indispensable.

Annotations.

"Ne quid nimis."

THE ASSESSMENT OF FŒTAL AGE.

The danger in medico-legal work of making dogmatic statements with regard to the age of a new- or still-born infant is exposed in the course of a critical study by Dr. J. N. Cruickshank and Dr. M. J. Miller[1] of the accuracy of the various accepted methods of estimating the age of the fœtus. The three methods commonly employed are: (1) Measurement of body-length and body-weight, (2) examination of the number and dimensions of the centres of ossification, and (3) estimation of the duration of gestation from the maternal menstrual history. In the series of 470 normal fœtuses examined, no one method or combination of methods of estimating fœtal age was found to be accurate in all cases, and the conclusion reached was that there can be no absolute certainty that the age of any individual fœtus has been correctly assessed. Attention is especially drawn to the extreme difficulty of estimating fœtal age during the eighth and ninth month. On the whole, body-length has been found more reliable than body-weight; this is of interest in view of the results of recent studies of postnatal development, in which the body-length has been found to be more reliable than body-weight as a guide to the progress of growth. The authors note that in the last three months of intra-uterine life the weight of the fœtus increases at a proportionately greater rate than that of any of the organs studied, except the spleen and thymus. It is during these months that most of the fat is laid on, and they suggest that this may explain the greater proportionate increase of the body-weight. They are cautious, however, in pointing out the limitations of the application of the results obtained from what they regard as too small a number of cases to allow more than tentative conclusions. It is curious that such a detailed and careful study of the normal fœtus has yielded so few positive results; the problem will probably have to be attacked from many different angles. We published last week an attempt on the part of Dr. Lucas Keene and Miss E. E. Hewer, D.Sc., to ascertain by combined chemical and histological methods the period at which the various organs begin to function in the fœtus. The work is suggestive, and may lead in the future to a further means of assessing the age of any individual fœtus.

DEVELOPMENT OF THE IRIS.

We are all well acquainted with the outward appearance of the iris, for we see many scores of examples of its variations every day, but few who are not in the ranks of anatomists or embryologists know much about its intrinsic structure, or are deeply informed concerning its development. Among the numerous papers read at the summer meeting of the Anatomical Society, held at Sheffield on June 27th and 28th, was an interesting communication from Miss I. C. Mann, dealing with some points in the development of the human iris. There are several things in the normal course of formation of this structure which seem to call for future research. The strange provision of a mesodermal stratum, for example, along the inner aspect of which the ectodermal structures extend secondarily, may require investigation into the early stages of evolution of the eyeball to explain its presence and meaning. The pupillary membrane is merely the attenuated central portion of this stratum, and it is to be expected theoretically that a structure that disappears so late as this membrane would leave frequent traces of its former presence. It is probable that such traces are more common than is generally supposed. Certain observations with recent and greatly improved methods of illumination and examination do, in fact, suggest that this is so. The curious and interesting formation of muscle in the iris by direct growth from the margin of the advancing ectodermal or retinal layers was well seen in some of the older sections shown. This origin, which has been known for a number of years, is without parallel in the body, for such ectodermal development as that of the muscles of the hair bulbs, if it actually takes place, is hardly comparable with what is really direct formation from a part of the brain itself. Miss Mann concerns herself with the development of the eye with a view to the explanation of congenital defects of the organ, but it is to be hoped, for the sake of definite knowledge on human formation, that she will continue these observations and researches into the minutiæ of structure and development.

HERPANGINA.

Under the name of "herpangina," Dr. John Zahorsky,[1] of St. Louis, describes a specific febrile disease characterised by the appearance of minute papules, vesicles, and ulcers in the throat. The disease occurs only in the summer months and affects children mainly between the ages of 3 and 10, though a few examples were seen in children between 12 and 15. The epidemic nature of the disease is shown by the affection occurring in groups. In family practice one child after another contracts the sore-throat. On bacteriological examination the same organisms are found as those which are usually present in ordinary sore-throat. The incubation period is from four to ten days. The disease begins with a sudden rise of temperature to 102°–105° F. Vomiting is very common, but not persistent. Headache and pains in the back of the neck are frequent. Nothing is seen on physical examination except the following characteristic appearances of the throat. There are minute vesicles from the size of a millet seed to that of a small pea on the anterior pillars or along the free margin of the soft palate, occasionally on the posterior part of the buccal mucosa or roof of the mouth, but much more frequently on the tonsils or pharyngeal mucous membrane. The vesicles rupture and leave punched-out ulcers, which become covered with a thin exudate. The lesions are never very numerous. In most cases the tonsils present a considerable inflammatory reaction. There is a slight leucocytosis. An irregular fever continues for two to four days, and then the temperature falls by lysis and the other symptoms subside. There are no complications or sequelæ.

THE RESCUE OF DRUG ADDICTS.

We have just received a report of the Homes for Inebriates Association, together with the fortieth annual report of Dalrymple House, Rickmansworth. This house, licensed under the Inebriates Acts, 1879–99, was established in 1883 for the treatment of gentlemen suffering from alcoholism or drug-habit and desirous of cure, and is conducted by a committee elected by an association of prominent churchmen, medical men. Members of Parliament, and others interested in the temperance question. The house is not run for profit, any surplus revenue being spent on improvements for the benefit of the patients. During the past year, of the 72 patients admitted, 55 entered as private patients and 17 under the Acts; 67 of these desired treatment on account of alcoholic excess, and five for drug-habit. The average length of residence was about two and a quarter months, or three and a half months under certificate. The resident medical superintendent, Dr. F. S. D. Hogg. remarks on the need of amendment of the Inebriates Acts in order to allow of non-criminal inebriates being compulsorily placed under supervision and treatment. He continues to receive appeals for advice as to the possibility of such control, and has to admit that, apart from financial or domestic pressure, only persuasion is open to those interested in these victims. So long as they commit no offence against the law they are free to degrade and ruin themselves, their families, and dependents; only, as a rule, when resources are exhausted, positions lost, and constitutions ruined, do they consent to place themselves under treatment. Earlier control would, Dr. Hogg feels sure, result, in many cases, in the retention of position and fortune. An appendix to the report gives particulars of a cumulative group of 1645 patients consecutively discharged. The occupation of these, in order of frequency, is set down as none, merchants, medical practitioners, military officers, clerks, manufacturers, farmers (including market gardeners), solicitors and engineers (equal), distillers (including brewers), clerks in holy orders and civil servants (equal), schoolmasters (including tutors), barristers-at-law, stockbrokers, artists and the theatrical profession, journalists—no other occupational group numbering as many as 20. The kind of inebriant used was in a vast preponderance of cases spirits in some form or other, beer alone occurring only 44 times and wine alone 40 times out of the total of 1645. The after-history of the cases shows how well repaid is the time and trouble incurred, for Dr. Hogg is able to note that about 40 per cent. of the 1645 are doing well, and another 6 per cent. are improved. The terms for admission to Dalrymple House are £6 6s. a week for those who remain three months or longer. Somewhat higher fees are charged for shorter periods. For admission under the Acts the report reminds those interested that the patient must sign a request for admission, specifying a period not exceeding two years, in the presence of a stipendiary magistrate, or better (without publicity) before a justice of the peace. Two persons of either sex, relations being eligible, must also sign a statutory declaration before a justice or commissioner for oaths. There is no necessity for the three signatures to be made at the same time or place; one or all can be signed at Rickmansworth, if preferred. The report, of which we have summarised the main features, is a document of great human interest, based upon clinical material observed and recorded now over a long period of years. We hope that the time is coming when the Association will issue a considered statement of the methods and results of treatment of drug-addiction at Rickmansworth.

POST-GRADUATE WORK ON ALPINE CLIMATE.

THE Davos Medical Association announces a post-graduate course for medical men on tuberculosis and the alpine climate, to be held at the Davos Research Institute during the week August 17th–24th. The course, which is the second of its kind, will be given in both French and German, a detailed prospectus to be issued later. It is now a little over six months since the formal opening of the Institute in the presence of a number of distinguished climatologists, Prof. Loewy being in charge of the physiological department and Prof. Dorno in charge of the meteorological. A number of interesting studies have already originated from the Institute, including work on the volume of the blood at high altitudes, the cholesterin-content of the blood in tuberculous patients, and the mechanism of blood regeneration. A paper appeared recently[1] by Privatdozent P. György, of Heidelberg, on the acid-base balance at high altitudes. Dr. György comes to the conclusion that in patients at rest in Davos there is a lowering of acid excretion in the urine, that climbing gives rise to a perceptible, but not unduly high, increase in the acid-ions eliminated, and that respiratory tetany is more easily induced in the same individual at a height than in the lowland. It is Prof. Loewy's hope that this research institute, the first of its kind in the mountains, may prove of definite value to the practitioner. The question what factors in the alpine climate are responsible for its effects remains still unanswered, as well as the cognate question whether the effect of insolation is to be explained on a chemical or on a physical basis. A library has already been collected at the Institute and is in process of cataloguing and classification, and it is hoped that the third department of the Institute—namely, the bacteriological-pathological—may soon be opened. The Institute is happy in having obtained the reversion of the scientific apparatus no longer required at the observation station of Muottas-Muraigl, above Pontresina. Among those attending the course there may well be some who will be glad to avail themselves of the opportunity for research along new and fruitful channels.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.

THE Medical Women's International Association opened its third Conference in London last week under the presidency of Dr. Esther Lovejoy, of New York. Some 300 members registered their names for these meetings, including 75 representatives of countries overseas; among these were medical women practising in such diverse parts of the world as Constantinople, Uruguay, Australia, and Norway. The time of the delegates, representing some 10,000 medical women, was largely occupied with business, as this was the first meeting of the fully constituted representative council under the amended constitution. After a preliminary meeting held in New York in 1919, at which it was decided to form a world-wide association of medical women, the constitution was discussed and passed at the second meeting held in Geneva in 1922. At the present meeting the necessary by-laws have been added. The general meeting of the Association was held on Wednesday morning, when after the President-elect, Lady Barrett, had been inducted to the chair, representatives from 15 of the 17 countries sending delegates to the meeting told of the numbers, organisation, and work of the medical women in their respective lands. The speakers were: Dr. Grieg (Australia), Dr. Becher-Reidenhof (Austria), Dr. R. Leacock (Canada), Dr. Dewetterova (Czecho-Slovakia), Dr. Thuillier-Landry (France), Dr. Heusler Edenhuizen (Germany), Dr. M. Balfour, C.B.E. (India), Dr. Signe Swensson (Norway), Dr. Grace Stevenson (New Zealand), Dr. A. Ilnicka (Poland), Dr. V. Lebedeva (Russia), Dr. Marie Ugon (Uruguay, South America), Dr. Marie Feyler (Switzerland), Dr. Safieh Ali (Turkey), and Dr. Katherine Manion (U.S.A.). It was announced that Dr. Jane Walker had been appointed treasurer to the Association. On July 17th a discussion took place on maternal morbidity, which is reported on p. 185. The Hospitality Committee, under the presidency of Dr. Jane Walker and its hon. secretary, Dr. Kathleen Lander, had arranged an attractive programme of entertainments and expeditions for members of the Congress. The proceedings opened with a reception and conversazione at the Royal Society of Medicine on July 14th. On the 15th Miss Aldrich-Blake entertained a large party to luncheon at the London (R.F.H.) School of Medicine for Women. In the afternoon of the same day the members were welcomed by the Archbishop of Canterbury and Mrs. Davidson at Lambeth Palace, and in the evening receptions were held by Lady Sybil Smith and by Lady Barrett. On Wednesday a luncheon party, given by the London Association of the Medical Women's Federation at the Botanical Gardens, was followed by a visit to the Royal Free Hospital, and in the evening a large gathering assembled at 10, Downing-street, where the Prime Minister and Miss Ishbel MacDonald welcomed the visitors on behalf of the Government. On Thursday the various provincial associations entertained the foreign guests to luncheon, some of the delegates from the dominions were present at THE LANCET luncheon to doctors from overseas dominions, and in the afternoon parties were invited to tea on the terrace of the House of Commons. In the evening the British Medical Women's Federation held its annual dinner at the Trocadero Restaurant, Piccadilly, for the success of which the admirable arrangements made by Lady Briscoe, M.B., were largely responsible. All overseas delegates were invited as guests and over 320 members and guests were present. The toast of "The Medical Women's International Association" was proposed by Prof. Graham Wallas and Mrs. Scharlieb, M.D., and responded to by Dr. Esther Lovejoy and Mme. Thuillier-Landry. "The Guests" was proposed by Dr. Jane Walker and replied to by Mrs. Fawcett, who was received with musical honours, and by Dr. Thelberg (U.S.A.). The proceedings concluded with "The Health of the Chairman," Lady Barrett, proposed by Dr. Walter Carr. On Friday morning the British members held their annual meeting, while a party of foreign delegates were shown over the museum of the Royal College of Surgeons of England by Sir Arthur Keith. Visits were paid to the Barbers' Hall and to the Apothecaries' Hall, and opportunity was provided for the foreign delegates to see the clinical work in various general and special hospitals and clinics. On July 19th a party of delegates was entertained at Bath, on the 20th at the East Anglian Sanatorium at Nayland, and on the 21st at Brighton.

RUPTURE OF THE SPLEEN FROM THERAPEUTIC MALARIA.

THERE is one aspect of the treatment of general paralysis of the insane by the artificial induction of malaria which has not yet received the attention it deserves. The subjects of general paralysis are often debilitated, feeble creatures, incapable of withstanding diseases which even the young and robust find most exhausting. In many countries in which malaria is endemic and syphilis is common, general paralysis is comparatively rare, and our knowledge of the action of one disease on the other is, therefore, very incomplete. We shall soon know more of this interaction, after more cases of general paralysis have been treated by the artificial induction of malaria. Together with encouraging results, a few disquieting accounts have been published of the effects of tertian malaria on the subjects of general paralysis. In *Le Scalpel* for May 10th Dr. M. Alexander records the case of a man, aged 50, admitted to hospital on Feb. 8th, 1924, suffering from general paralysis. For several months there had been progressive mental deterioration, with great irritability and incoherency. He looked much older than he was, he was easily fatigued, the tendon reflexes were exaggerated, and the skin reflexes diminished. The examination of the cerebro-spinal fluid confirmed the clinical diagnosis, and on April 9th he was given a subcutaneous injection of 5 c.cm. of blood from a patient suffering from tertian malaria. Ten days later a bout of fever developed, but it did not conform to type, a rise of temperature occurring every second day. The patient underwent with apparent impunity and ease eight attacks of fever, the temperature reaching 39° C. After the eighth attack he was seen to turn pale and to collapse on his bed, where he was found to be dead. The necropsy confirmed the diagnosis of general paralysis without, however, revealing any lesion of the brain. The kidneys were intact, whereas there was some cardio-arterial sclerosis. The abdominal cavity was full of blood derived from a soft spleen which had ruptured, the appearance of the spleen suggesting a veritable explosion within it. As long as such an incident is isolated it need not be regarded as more than a clinical curiosity. General paralysis of the insane is such a terrible disease that it is justifiable to take even great risks in the attempt to check its progress, but if the incident just described recurs frequently, it is conceivable that treatment with malaria may have to be confined to those cases of general paralysis in which there is a fair margin of general vitality and recuperative power. In Denmark advanced cases of general paralysis have been used as human thermostats in order to keep a strain of tertian malaria alive by frequent passage, and it will be interesting to learn what effect the malaria has had on these incurable cases.

MEDICAL STUDIES IN VIENNA.

ADVANCED English medical students have indicated a wish recently to continue their medical studies in the Medical Faculty of Vienna, and that faculty has now decided to allow such students to enter their schools, and further, will recognise in the case of the unqualified men the studies already attended in English medical schools. Similarly, there will be recognition of the examinations passed in England which correspond to the Austrian First Professional Examination—namely, physics, biology, chemistry, anatomy, histology, and physiology—but exemption will not be granted from the first Austrian examination unless a candidate has passed in all of these subjects in England, as they constitute one examination in Austria.

DECOMPOSITION OF URINE AND ITS PREVENTION.

IT is often desirable to collect the urine that is passed during the 24 hours in order that the analysis of such an abnormal constituent as sugar may give correct information as to the total daily output of sugar. To trust to a random sample of urine passed at any hour of the day is to court gross inaccuracy. But the collection of all the urine passed in the 24 hours does not get over this difficulty unless its decomposition is prevented by some means or other, for ammoniacal decomposition and changes in the sugar content of the urine are apt to stultify the results of an analysis. In a paper in *Norsk Magazin for Lægevidenskaben* for June, Dr. T. Brandt and Dr. R. C. Stokstad have published investigations throwing light on this problem and providing a simple solution to it. They have tested a variety of disinfectants and have found that many of the most common, such as formalin and carbolic acid, are unsuitable because of their capacity to reduce sugar. They have found toluol act satisfactorily, but not for longer than 24 hours. The same could be said of thymol. Xylol proved to be an unsatisfactory disinfectant, and so did chloroform, probably because it was too volatile for the purpose. Perchloride of mercury in a strength of 0·5 per 1000 prevented decomposition even for 48 hours, and toluol prevented decomposition for 24 hours, when 15 c.cm. were added to a litre and a half of urine and thoroughly shaken. The same effect could be obtained with 15 c.cm. of a 10 per cent. solution of thymol in alcohol. But most of these disinfectants possess certain disqualifications. Either they are too expensive for routine hospital work or they are (with the exception of perchloride of mercury) inadequately soluble in the urine, which has to be shaken vigorously to obtain the desired result. Another objection to toluol is its inflammable properties, and the greasy coating it leaves on the test-tube. In view of all this, the authors have abandoned the idea of preventing decomposition of urine with the help of disinfectants, and they have done so the more willingly as they have come to the conclusion that the problem is one of chemistry and physics as well as of bacteriology. For, as they point out, the rate of decomposition of various urines is far from uniform, even when the bacterial contamination is uniform. Their investigations have shown that the best solution to this problem is to be found in a study of the hydrogen-ion concentration 'of the urine, a sample with a pH under 5·0 showing practically no ammoniacal decomposition even after 24 hours in a thermostat. All that is therefore needed to prevent decomposition of urine is to render it highly acid, and for this purpose the authors recommend the addition of about 15 c.cm. of HCl to every litre and a half of urine. Any other acid will serve the same purpose except nitric acid, which destroys various organic substances.

PSYCHOLOGICAL TESTS OF EDUCABLE CAPACITY.

THE report[1] of the Consultative Committee of the Board of Education on psychological tests of educable capacity and their possible use in the public system of education has just been issued. After an historical sketch of the development of the psychological tests, and a discussion on the merits and disadvantages of the various types of tests and their scope, the Committee proceeded to consider "intelligence" tests in connexion with ordinary examinations intended primarily to test ability. The possibility of such tests in schools of different types and of standardised scholastic, vocational, and physical tests, and tests of memory, perception, and so forth, affording subsidiary information is also considered. The provision of courses for teachers in experimental psychology and the question of taking steps to coördinate and organise research and to distribute information bearing on the application of psychological and statistical methods to education are also discussed. In summarising the conclusions arrived at, the Committee note a general agreement that tests of "intelligence" are of value as supplements to, but not as substitutes for, the present methods of estimating individual capacity. Group tests are recommended for children over 10 and for adults as easier to apply, mark, and interpret by teachers with but little psychological training; individual tests, which are more suitable for young children, require application by an expert. All tests need considerable discretion in their interpretation. As to the bearing of psychological tests on public examinations, it is regarded as probable that in time the whole theory and technique of ordinary examinations will be modified by the application of the principles adopted in constructing and standardising intelligence and scholastic tests. The need for study of the legitimate aims and inevitable limitations of viva voce examinations and their technique is brought to the attention of psychologists. In view of the desirability of coördinating research, it is suggested that the Board of Education, either acting independently or in association with other Government departments interested in psychological tests, should set up an advisory committee to work in union with university departments of psychology and other organisations.

THE house and library of the Royal Society of Medicine will be closed during the whole of August for cleaning and repairs.

MR. DAVID P. D. WILKIE, F.R.C.S., has been appointed by the Curators of the University of Edinburgh to the Chair of Surgery, which has been vacant since the retirement of the late Prof. Alexis Thomson last October. The appointment is for a definite period of ten years from next October. Mr. Wilkie is at present assistant surgeon in the Edinburgh Royal Infirmary, and is lecturer on clinical surgery in the University of Edinburgh.

INDEX TO "THE LANCET," VOL. I., 1924.

THE Index and Title-page to Vol. I., 1924, which was completed with the issue of June 28th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers wishing to receive the Indexes regularly as published should indicate this desire.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXI.—ACUTE ANTERIOR POLIOMYELITIS.

IN the treatment of a disease an accurate conception of its pathology is an essential. The pathology of acute anterior poliomyelitis divides itself, when looked at from a therapeutic standpoint, into three stages. These may be labelled for convenience the stage of onset, the stage of destruction, and the stage of repair.

Stage of Onset.

The stage of onset is not always evident. When it occurs its symptoms are often vague. Fever, malaise, sore-throat, perhaps some slight gastro-intestinal disturbance are all accompaniments of the onset of many other commoner diseases. Not until the second stage, that accompanied by the development of a sudden paralysis, does the enemy reveal himself, and then at a time when his damage is already half done. But it is in the first stage of the illness that treatment may be really effective and when diagnosis should ideally be made; *in the presence of an epidemic* there are two phenomena that may lead to a correct diagnosis before the onset of paralysis. Pain in the limbs and spine, sometimes in the former case so severe as to suggest acute rheumatism, may precede the paralysis by 24 hours. A lymphocytosis in the cerebro-spinal fluid is found almost invariably during the first stage. Two therapeutic measures are of value at this period, serum given intrathecally and intravenously and large doses of urotropin administered by the mouth.

Serum Treatment.—The serum should be that of patients some weeks convalescent from the disease, but as the immunity conferred by attacks of filter-passing organisms is both great and prolonged it is probably that serum is still of protective value up to a period of five years. The blood (200 c.cm.) should be collected in a flask previously rinsed out with sterile normal saline solution. After the clot has separated firmly the serum (about 100 c.cm.) is drawn off and kept in a cool place. It is administered both intrathecally and intravenously on two successive days, about 25 c.cm. being given by both routes on each day. Malaria and syphilis must, of course, be excluded in the donor. S. Flexner and P. A. Lewis showed that, whereas intracerebral inoculation of the virus into monkeys invariably produced the disease, yet if human serum derived from convalescent children were given to the animals intrathecally paralysis in some cases was delayed and in others completely prevented. In the case of an epidemic such convalescent serum may well be procurable, but otherwise horse serum can be given. There is some evidence that this also contains antibodies against the virus. Whichever is used the administration is of greatest value in the first or pre-paralytic stage, but *is probably still of some value for the first two or three days after paralysis has appeared.* If horse serum is used it may be necessary to desensitise the child against the occurrence of anaphylaxis by successive half-hourly doses of ♏i., ½ c.cm., 5 c.cm., before giving the full intravenous and intrathecal doses.

Urotropin.—As for convalescent serum, so for urotropin, there is experimental evidence of its probable value in acute poliomyelitis. S. Flexner and Clark have shown that if large doses of the drug are administered to monkeys an appreciable amount is soon to be detected in the cerebro-spinal fluid; and, furthermore, that if the monkeys are during this time inoculated with the virus of acute poliomyelitis paralysis can be delayed and even in some cases prevented. There is no doubt that to obtain a therapeutic effect large doses should be given.

---

[1] H.M. Stationery Office. 1924. 2s.

the drug being pushed boldly for a short period. G. F. Still quotes the case of a child, 21 months old, to whom 10 gr. were given every two hours for 24 doses. These heavy doses are the more allowable in that the period during which active damage to the central nervous system occurs is a short one, and it is during that time, amounting to three or four days in all, that the action of the urotropin in the theca is desired. The organ most likely to be damaged in any way by the urotropin is the kidney, and careful daily urinary examinations for albumin and blood should be made as a routine. Urotropin may also wisely be given for a week to children who have come into contact with cases of the disease as a prophylactic measure.

Stage of Destruction.

This stage lasts probably for five or six days. During that time the damage to the nerve tissues is done. This damage is to be divided into two categories, permanent and temporary. Some of the anterior horn cells are so severely hit that recovery can never occur, others are only partially poisoned or mechanically interfered with by their proximity to the areas of attack and the resulting local inflammatory changes. Furthermore, it must be remembered that hyperæmia is found post mortem in parts of the central nervous system far from the paralysed areas. It is with a view to resting these insulted rather than wounded tissues that treatment is designed at this period. The patient is kept at rest in a quiet, airy room, bright light is excluded, and visitors are not allowed for the first week. Bromides and even chloral can reasonably be given to shield the nervous system from all excessive stimuli. As mentioned above, serum and urotropin should be given for the first 48 hours of paralysis.

Stage of Repair.

The stage of repair may last for two years, and it thus comprises the large majority of cases of infantile paralysis met with in practice. Its successful treatment is a lengthy, often a tedious, business. But this conception—one of almost invisibly slow but steady progress—is one to be held by the medical attendant and to be explained carefully to the parents of the patient. Treatment of the disease is thus a campaign rather than a battle, and for its success considerable attention to detail is necessary. Since the essential pathological lesion involves the anterior horn cells it is obvious that the peripheral manifestations will be motor and trophic. The trophic lesion results in peripheral vasodilation and loss of heat, and must be compensated for, in the case of the legs, by the wearing of long woollen stockings. If these are insufficient further coverings, possibly quilted, must be made and worn: paralysed arms are similarly treated.

It is, however, the damage to the motor mechanism that demands the greatest assiduity and care in treatment. The treatment consists of (*a*) immobilisation, (*b*) massage, (*c*) passive and active movements, (*d*) repair operations. As soon as the diagnosis is sure an exact investigation must be made as to which muscles are paralysed. This can be done by stimulating their movements and by carefully watching, or more accurately by noting their electrical reactions. The limb should then be immobilised without delay in such a position that the paralysed muscles are relaxed and their antagonists slightly on stretch. There is nothing so fatal to the complete recovery of a paralysed muscle as tension. On the other hand, tension of the sound muscles causes a reflex relaxation on the part of the antagonistic unsound muscles. The exact form of immobilisation does not greatly matter, but two points should be kept in mind; the support should be light and should be easily removable to permit of daily massage. The best material is celluloid.

Massage.—The most valuable ally in the campaign waged for the recovery of the limb from paralysis is the mother. She should understand that the task will last for two years, and she should, if a trained nurse is not permanently available, be taught to massage her child. During the first month or two she should watch the process and should learn how to carry it out herself. Ultimately there is no reason why she should not shoulder the whole burden herself. The instructions given her should be specific. Those in use at the Hospital for Sick Children, Great Ormond-street, are comprehensive and valuable; they are as follows:—

Rubbing.—This must be done for a quarter of an hour twice a day. Lay the child on a bed.

1. Rub the paralysed leg from the foot right up to the top of the thigh. Rub upwards only. Put the broad part of your hand on the back of the child's leg. In rubbing the thigh put your hand first on the back of the thigh and afterwards on the front, but always rub upwards and be sure to go as high as the loins. Whilst rubbing with your right hand hold the foot with your left. Use for rubbing any kind of oil.
2. Take hold of the child's leg with your two hands just above the ankle. Rub round the leg with your two hands in opposite directions, as though you were wringing out sheets. Work up the leg and thigh from the foot up to the top of the thigh in the above manner.
3. Take the child's calf with your two hands. Put your fingers to the back part of the leg and your thumbs to the front. Squeeze the soft parts out between your finger and thumbs so as to flatten the leg out and make it as wide as possible. Work right up the leg and thigh in this manner.
4. Put your right hand over the front of the knee and your left under the foot. Push up the foot and, holding your right hand in front of the knee, you will prevent yourself doing any harm. You want, if possible, by pushing the foot to make the child push against your left hand with all its might. This is the most important of all exercises.
5. Flip every part of the leg and thigh with your fingers so as to make the whole of the limb quite red and warm.
6. Gently rub up and down all over. This will take away the stinging which was left by the last movement.

Passive Movements.—At the end of the day's massage the joints of the affected limb should be moved passively in all their normal directions, especially in the direction towards which they would be drawn by the paralysed muscles.

Active Movements.—The child should be encouraged to try to move the paralysed limb and the slightest twitch of an affected muscle should be drawn attention to and praised. It will sometimes be found that such movements will first be noticed in a warm bath, and this fact should be remembered and impressed upon the mother.

Repair Operations.—The advances made in orthopædic surgery make it probable in the majority of cases that further functional improvement can be obtained after all active repair has ceased, either by tendon transplantation or by joint fixation or by some other mechanical shift. Since, however, repair may progress for two years it is wise to postpone operative treatment until it is certain to what extent such a measure is necessary.

Chief Assistant, St. Bartholomew's Hospital; Physician,
East London Hospital for Children, Shadwell.

QUEEN ALEXANDRA SANATORIUM FUND.—The annual report for 1923–24 shows that 28 grants were made to 14 men and 14 women, who were thus enabled to take a prolonged cure in the Alps during the past winter season. The average stay amounted to 158 days, and the winter was a fine one, offering the best possible conditions for successful treatment. The average cost to the Fund of each patient has been about £15 10*s.*, or at the rate of 6*s.* 8½*d.* per day, the total cost per patient per day for maintenance and treatment being approximately Fr.16. The patients have, therefore, paid just under 50 per cent. of the cost of their treatment. Of immediate results, 22 gained in weight, in 9 the disease was arrested, and 7 others were improved; 3 cases were treated with tuberculin injections, 2 with vaccine injections, and 4 with antiseptic inhalations. It has been decided to make a limited number of grants during the present summer. The sanatorium at Davos was only reopened on Oct. 15th, 1923, but experience is already sufficient to show an extensive demand for a scheme of assistance on the lines of the Fund.

Special Articles.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.

MATERNAL MORBIDITY: ITS CAUSES AND PREVENTION.

AT the scientific session of this Association, held on July 17th, the Chairman, Lady Barrett, President of the Association and of the British Medical Women's Federation, in an opening paper, pointed out that the causes of maternal morbidity are, in effect, the same as those that account for our maternal mortality—viz., sepsis, hæmorrhages, toxæmias of pregnancy, difficulties in labour, and complicating diseases, such as heart disease. The general health of the woman protects her to a very large extent against almost all these dangers; it guards her from the toxæmias, affects the activity of the uterus in labour, contributes to the endurance of the patient in the event of long or difficult labour, and provides the necessary resistance to the invasion of organisms.

The Problem as one of General Health.

The problem of maternal morbidity was, therefore, the problem of the woman who is not in perfect health, and the line of attack must be that of general health and conditions of living. All working for the improvement of motherhood—doctors, nurses, midwives, health visitors, and administrators—were, said the speaker, engaged primarily in the process of observation, noting when and where and how the health of the expectant mother deviates from the line of normality, and in this respect the doctors, nurses, and administrators were dependent to a very large extent on the health visitor, who has greater leisure for such observations. In theory we knew enough to reduce the present maternal mortality and its dependent maternal morbidity by one half, as had, indeed, been done in certain areas of the country. Our task was to see that this knowledge was put into practice in every county and district of the land.

Dame Janet Campbell gave an account of the methods and mechanism employed by the Ministry of Health and local authorities in this country for the assistance of mothers and infants. She pointed out that, while the infant mortality-rate had been very considerably reduced during the last 20 years, the maternal mortality-rate (1 in 250) had remained almost unaltered, although the introduction of the Midwives Act seemed to have reduced the puerperal sepsis rate to some extent.

Dr. Margaret Balfour, representing India, told the Conference of the conditions there. The local midwives, though ignorant of modern methods of asepsis, were capable of dealing with ordinary cases, though their ineradicable habit of unnecessary interference rendered them a source of danger; but in all abnormal cases the rate of mortality reached an enormously high figure. In Bengal, where the majority of the primiparæ were under 13 years of age, over 16,000 girls died in childbirth in 1921. In the Punjab a medical woman had recently been appointed to assist the Director of Public Health, but very much more in this direction yet remained to be done.

Value of Lactation.—Importance of Diet.

Dr. Helen Boyle (Brighton) spoke of the nervous and mental aspects of the subject and stressed the extreme rarity of puerperal insanity in mothers who nursed their babies. There was far too great a tendency to take the baby off the breast at the slightest sign of nervous symptoms, and to overlook the fact that lactation is not only a secretion for the benefit of the infant, but also an excretion for the benefit of the mother. She concluded with a plea for the observation and early treatment in every case of early nervous developments after childbirth.

Dr. Effa Davis (Chicago) said that as a result of her 30 years' experience of maternity work in the United States, she had come to the conclusion that much might be done to improve the conditions of labour in healthy women. For instance, there was the type that ate too much and exercised too little; they had too big children. By careful regulation of the regimen of the pregnancy period it was always possible to reduce the size of the child and thus reduce the difficulties of parturition. Dr. Davis spoke with admiration of the School of Domestic Science at King's College for Women, Campden Hill, and hoped for the wide extension of such work until every woman was taught, from childhood upwards, how to look after herself and her home in the best possible way. Two practical prophylactic points which Dr. Davis had found useful against sepsis were the employment of oakum instead of cotton for pads, thus introducing a mildly antiseptic atmosphere; and the custom of allowing all normal cases to rise from bed for the evacuation of the bladder and bowel, thus allowing the force of gravity to play its part in the drainage of the uterus.

The Blood Pressure Factor in Eclampsia.

Frau Dr. Heusler Edenhuizen (Berlin) spoke of some investigations bearing on the prophylaxis of eclampsia. It was found in Germany during the years 1918–20, when there was an average loss in weight among women of 17 kilos each, that there was a striking decrease in the incidence of eclampsia, although all parturient women were in a state of very great exhaustion. These women were found to have a blood pressure as low as 116 mm. and this appeared to be the significant factor. Dr. Edenhuizen had found that of all methods tried for reducing the blood pressure twilight sleep was the most valuable, reducing the pressure sometimes from 180 mm. to 130 mm. in two hours. She went on to speak of puerperal sepsis, and stated that she had found, without exception, that where sepsis occurred, in spite of the most rigid antiseptic measures, there had been coitus within a few weeks of labour. Among the peasants of the Rhine valley there was a superstition that coitus during the first pains renders labour easier: sepsis was there very prevalent and no antiseptic measures seemed able to counteract it. Among the educated classes of Berlin Dr. Edenhuizen had been able greatly to reduce the incidence of sepsis by forbidding intercourse after the fifth month.

Dr. Sylvia Chapman (New Zealand) told of the "Safe Maternity Campaign" which had recently taken place there. In the last five years 755 lives had been lost through puerperal deaths among a population of 1,000,000, and this was attributed to two causes—viz., the lack of proper antenatal supervision and the existence of private maternity hospitals run by midwives not fully competent for the work. A few antenatal clinics had recently been started in connexion with the St. Helen's Hospitals (the Government maternity hospitals), but they were as yet poorly attended, and there is need of education among women as to the importance of the antenatal period.

Frequency of Gonococcal Infections.

Miss Frances Ivens (Liverpool) emphasised the great importance of antenatal care, and the significance of the gonococcus, often latent or unrecognised, in the production of puerperal sepsis. She urged a more careful inquiry into the history of the patient, both maternal and general, and into the nature of any discharge; and made a plea for more and better equipped maternity beds, and better teaching of medical students in this subject.

Dr. Alina Ilnicka (Warsaw) read a paper on the morbidity amongst working mothers, which was greater than that amongst women who do not work at any trade or profession, showing that there must be something wrong in the woman worker's way of living. Such occupations as sewing machine pedalling, ironing, factory work requiring continuous treadling the drug being pushed boldly for a short period. G. F. Still quotes the case of a child, 21 months old, to whom 10 gr. were given every two hours for 24 doses. These heavy doses are the more allowable in that the period during which active damage to the central nervous system occurs is a short one, and it is during that time, amounting to three or four days in all, that the action of the urotropin in the theca is desired. The organ most likely to be damaged in any way by the urotropin is the kidney, and careful daily urinary examinations for albumin and blood should be made as a routine. Urotropin may also wisely be given for a week to children who have come into contact with cases of the disease as a prophylactic measure.

Stage of Destruction.

This stage lasts probably for five or six days. During that time the damage to the nerve tissues is done. This damage is to be divided into two categories, permanent and temporary. Some of the anterior horn cells are so severely hit that recovery can never occur, others are only partially poisoned or mechanically interfered with by their proximity to the areas of attack and the resulting local inflammatory changes. Furthermore, it must be remembered that hyperæmia is found post mortem in parts of the central nervous system far from the paralysed areas. It is with a view to resting these insulted rather than wounded tissues that treatment is designed at this period. The patient is kept at rest in a quiet, airy room, bright light is excluded, and visitors are not allowed for the first week. Bromides and even chloral can reasonably be given to shield the nervous system from all excessive stimuli. As mentioned above, serum and urotropin should be given for the first 48 hours of paralysis.

Stage of Repair.

The stage of repair may last for two years, and it thus comprises the large majority of cases of infantile paralysis met with in practice. Its successful treatment is a lengthy, often a tedious, business. But this conception—one of almost invisibly slow but steady progress—is one to be held by the medical attendant and to be explained carefully to the parents of the patient. Treatment of the disease is thus a campaign rather than a battle, and for its success considerable attention to detail is necessary. Since the essential pathological lesion involves the anterior horn cells it is obvious that the peripheral manifestations will be motor and trophic. The trophic lesion results in peripheral vasodilation and loss of heat, and must be compensated for, in the case of the legs, by the wearing of long woollen stockings. If these are insufficient further coverings, possibly quilted, must be made and worn; paralysed arms are similarly treated.

It is, however, the damage to the motor mechanism that demands the greatest assiduity and care in treatment. The treatment consists of (*a*) immobilisation, (*b*) massage, (*c*) passive and active movements, (*d*) repair operations. As soon as the diagnosis is sure an exact investigation must be made as to which muscles are paralysed. This can be done by stimulating their movements and by carefully watching, or more accurately by noting their electrical reactions. The limb should then be immobilised without delay in such a position that the paralysed muscles are relaxed and their antagonists slightly on stretch. There is nothing so fatal to the complete recovery of a paralysed muscle as tension. On the other hand, tension of the sound muscles causes a reflex relaxation on the part of the antagonistic unsound muscles. The exact form of immobilisation does not greatly matter, but two points should be kept in mind; the support should be light and should be easily removable to permit of daily massage. The best material is celluloid.

Massage.—The most valuable ally in the campaign waged for the recovery of the limb from paralysis is the mother. She should understand that the task will last for two years, and she should, if a trained nurse is not permanently available, be taught to massage her child. During the first month or two she should watch the process and should learn how to carry it out herself. Ultimately there is no reason why she should not shoulder the whole burden herself. The instructions given her should be specific. Those in use at the Hospital for Sick Children, Great Ormond-street, are comprehensive and valuable; they are as follows:—

Rubbing.—This must be done for a quarter of an hour twice a day. Lay the child on a bed.

1. Rub the paralysed leg from the foot right up to the top of the thigh. Rub upwards only. Put the broad part of your hand on the back of the child's leg. In rubbing the thigh put your hand first on the back of the thigh and afterwards on the front, but always rub upwards and be sure to go as high as the loins. Whilst rubbing with your right hand hold the foot with your left. Use for rubbing any kind of oil.
2. Take hold of the child's leg with your two hands just above the ankle. Rub round the leg with your two hands in opposite directions, as though you were wringing out sheets. Work up the leg and thigh from the foot up to the top of the thigh in the above manner.
3. Take the child's calf with your two hands. Put your fingers to the back part of the leg and your thumbs to the front. Squeeze the soft parts out between your finger and thumbs so as to flatten the leg out and make it as wide as possible. Work right up the leg and thigh in this manner.
4. Put your right hand over the front of the knee and your left under the foot. Push up the foot and, holding your right hand in front of the knee, you will prevent yourself doing any harm. You want, if possible, by pushing the foot to make the child push against your left hand with all its might. This is the most important of all exercises.
5. Flip every part of the leg and thigh with your fingers so as to make the whole of the limb quite red and warm.
6. Gently rub up and down all over. This will take away the stinging which was left by the last movement.

Passive Movements.—At the end of the day's massage the joints of the affected limb should be moved passively in all their normal directions, especially in the direction towards which they would be drawn by the paralysed muscles.

Active Movements.—The child should be encouraged to try to move the paralysed limb and the slightest twitch of an affected muscle should be drawn attention to and praised. It will sometimes be found that such movements will first be noticed in a warm bath, and this fact should be remembered and impressed upon the mother.

Repair Operations.—The advances made in orthopædic surgery make it probable in the majority of cases that further functional improvement can be obtained after all active repair has ceased, either by tendon transplantation or by joint fixation or by some other mechanical shift. Since, however, repair may progress for two years it is wise to postpone operative treatment until it is certain to what extent such a measure is necessary.

Geoffrey Bourne, M.D., M.R.C.P. Lond.,
Chief Assistant, St. Bartholomew's Hospital; Physician,
East London Hospital for Children, Shadwell.

Queen Alexandra Sanatorium Fund.—The annual report for 1923–24 shows that 28 grants were made to 14 men and 14 women, who were thus enabled to take a prolonged cure in the Alps during the past winter season. The average stay amounted to 158 days, and the winter was a fine one, offering the best possible conditions for successful treatment. The average cost to the Fund of each patient has been about £15 10*s.*, or at the rate of 6*s.* 8½*d.* per day, the total cost per patient per day for maintenance and treatment being approximately Fr.16. The patients have, therefore, paid just under 50 per cent. of the cost of their treatment. Of immediate results, 22 gained in weight, in 9 the disease was arrested, and 7 others were improved; 3 cases were treated with tuberculin injections, 2 with vaccine injections, and 4 with antiseptic inhalations. It has been decided to make a limited number of grants during the present summer. The sanatorium at Davos was only reopened on Oct. 15th, 1923, but experience is already sufficient to show an extensive demand for a scheme of assistance on the lines of the Fund.

ought not to be costly. The provision of baths should depend upon the public opinion of the locality. Parlours, too, were rather amenities than essentials, and should only be provided if the occupiers were prepared to pay the extra rent involved. He concluded his address with a note of warning that the pursuit of sanitation and sanitary comforts was not a sufficient aim in itself, and could only be safely practised by a nation which realised that these things, important as they are, are only valuable according as they bring up a race which, governed by the spiritual idea of service, becomes more capable of effort and more equal to the achievement of the work which its world-wide responsibilities demand.

The Health Exhibition.—On July 14th also the Health Exhibition was opened by the Lord Mayor of Liverpool, supported by the mayors of neighbouring boroughs. The exhibition was well arranged in a building well adapted for the purpose, but situated rather far from the general meeting place and the attendance at the exhibition suffered from this fact.

The Sections.

The business of the Congress was conducted at five sessions: (A) Sanitary Science; (B) Engineering and Architecture; (C) Maternity and Child Welfare, including School Hygiene; (D) Personal and Domestic Hygiene; and (E) Industrial Hygiene. There were also seven conferences—namely, of representatives of sanitary authorities, of representatives of port sanitary authorities, of medical officers of health, of engineers and surveyors to sanitary authorities, of veterinary inspectors, of sanitary inspectors, and of health visitors.

Sir William Leishman, in his presidential address to Section A, made a strong plea for closer collaboration between the hygienist and the pathologist. His communication was followed by a discussion on the uses which might be made of the Schick test and immunisation for diphtheria, a valuable paper contributed by Dr. R. A. O'Brien being debated by Dr. H. P. Newsholme and Dr. E. H. R. Harries. The general opinion appeared to be that the staff of fever hospitals ought to be protected by immunisation, and that the method might be usefully adopted for the control of diphtheria in residential and other schools. Several speakers from U.S.A., including Prof. Welsh from Johns Hopkins University, took part in the discussion and showed that immunisation is being practised on a much larger scale in America. It was suggested that in some parts of America the disease is much more fatal than in this country, that the American population is much more ready to submit itself to measures of this kind, and that experience in this country with regard to vaccination does not hold out much prospect of the successful immunisation of the whole population against diphtheria.

The question of education in hygiene and propaganda with regard to V.D. gave rise to an animated discussion in Section A, opened by Dr. I. Feldman and Dr. Winifred Piggott.

The proceedings of the Section of Industrial Hygiene were opened by a valuable address from Dr. T. M. Legge, Senior Medical Inspector of Factories, which was followed by a suggestive paper delivered by Lieut.-Col. F. E. Fremantle, M.P., which we publish in abridged form on p. 200 of this issue of THE LANCET. Both papers showed how little progress has been made with regard to industrial hygiene in this country.

On Thursday, July 17th, there was a crowded gathering at the meeting of Section C on Maternity and Child Welfare to hear the discussion on antenatal clinics. The subject was ably opened by Dr. F. Cook, who was followed by Prof. Louise McIlroy. Unfortunately, the discussion was to be succeeded on the same morning by a discussion on the system of charging for the medical services provided for the maternity and child welfare centres and in the schools. The result was that in the first discussion the speakers were much hurried and there was little opportunity for general discussion. At the meeting of the port sanitary authorities the question of the sanitation of the mercantile marine was dealt with by Dr. W. Hanna and Dr. J. Howard Jones. In the course of the discussion it was shown that the arrangements for the crews leave much to be desired. It was stated that some shipowners were reverting to the old bad type of crews' quarters in the forecastle usual before the war.

Meat Inspection.

The question of meat inspection was discussed by the veterinary inspectors. Mr. H. L. Torrance showed that the illicit dealing in diseased meat carried on in the underworld of the meat trade was very much greater than was generally known and the inference was that it must be very profitable. A resolution was passed expressing the view that public abattoirs should be substituted for private slaughter-houses, so that all animals intended for human food could be submitted to both ante-mortem and post-mortem examination.

At the conference of medical officers of health on the last day Prof. W. S. Lazarus-Barlow put forward a large scheme for dealing with cancer. The scheme included arrangements for following up cases after operation and for the provision of centres for radium and X ray treatment for the whole country. He estimated that for a population of 42 millions £340,000 worth of radium should be available and might be allocated to seven centres, and that 14 fully equipped X ray centres would be required. It would also be necessary to have some State-aid for bringing the patients to, and treating them at, the centres. He suggested coöperation between the voluntary hospitals and Poor-law infirmaries to provide the necessary accommodation, and further stated that, on his advice, a scheme on these lines had already been started in one of the great dominions overseas. The mother country, therefore, should not lag behind.

The general arrangements for the Congress were, on the whole, very good.

THE LANCET LUNCHEON
TO
OVERSEAS MEDICAL REPRESENTATIVES.

ON Thursday, July 17th, in the Oak Room of the Hotel Victoria, London, a luncheon was given by THE LANCET to the Overseas Medical Representatives now on a visit to this country in connexion with the British Empire Exhibition. Some sixty guests accepted the invitation.

After the loyal toasts had been duly honoured, Sir Ernest Hodder-Williams, C.V.O., the Chairman of THE LANCET, who presided, welcomed the guests. He said that though on occasion he had been compelled to take unpleasant prescriptions from doctors he was not on this occasion going to get some of his own back on doctors by making a long speech to them. THE LANCET was delighted to show their welcome to the overseas members of the medical profession, and he and the staff were glad to have the honour of making personal acquaintance with a large group. THE LANCET had recently celebrated its centenary, and in the hundred years which had thus been commemorated there was nothing more remarkable than the way in which there had come into being a real unity of work and purpose in medicine among the English-speaking peoples, a constant interchange of views and works to the immense benefit of medicine and of mankind. The overseas dominions had given to the old country of their very best, while we on our part had certainly reciprocated. British medicine recognises no sundering seas. Science has no nationality: knowledge, as Pasteur said, "is the patrimony of humanity, though.

and other forms of work acting as a vibratory massage of the uterus, left their mark in such disabilities as dysmenorrhœa, difficult healing of pelvic wounds, and a high percentage of abortions. Dr. Ilnicka urged more careful factory inspection, with these points in view, closer cöoperation between doctor, masters, and operatives, and selection among the workers, so that the woman was put in a position to produce the maximum of work with the minimum of fatigue. Not only was the manual worker badly situated, but the professional woman also, who, in Poland at any rate, did her six or eight hours work of teaching, clerking, or what not, and then returned to do all the duties of the home, very few being able to afford a maid. In Poland women were given eight weeks' leave before and six weeks after childbirth, and there was a possibility of the latter being increased to 12 weeks. The infant mortality-rate was 39 per cent. lower in cases where the mother remained away from work three months or more, than in cases where the baby was put on the bottle at the end of a month.

Dr. Becher-Reidenhof (Vienna) spoke of tuberculosis during pregnancy, and stated that the presence of the bacilli was not in itself dangerous, but that serious symptoms, such as high temperature and hæmoptysis, were doubly grave at such a time. The prognosis in the event of induction depended on the degree of infection and the duration of pregnancy, the outlook being most hopeful the earlier the uterus was emptied.

Dr. Kate Mead (Middleton, U.S.A.) spoke of the administrative methods in use in the U.S.A. since the introduction, two years ago, of the Bill allotting to each State a sum of money, to be doubled by the State, for the care of pregnant women. In her town there were nine visiting nurses among the 25,000 inhabitants, and they went to the houses of rich and poor alike, while every woman, no matter what her means might be, expected to go to the State hospital for her delivery. The midwives were not very good, and Dr. Mead urged more careful teaching of nurses in regard to asepsis, and suggested that sterile gloves should be worn for all services such as handling of bed-pans and bed-trays.

Dr. Rosamund Leacock (Canada) dealt with the bacteriological aspect of puerperal sepsis, after outlining the conditions of maternity work in Canada, where there were practically no midwives, only a few women who were allowed to manage cases living more than 30 miles from a doctor. She divided the causes of sepsis into extrinsic and intrinsic. Under the former heading she urged inquiries into any condition of slight sepsis in members of the household, since the streptococcus that is relatively unimportant in the ear or antrum of a relative might be fatal if it found its way into the uterus of the lying-in woman. Under the intrinsic causes she pointed out how a streptococcus could live for years in the Fallopian tubes, and said that no pregnancy should be allowed for at least two years after any pelvic infection.

Maternity Work in Russia.

Dr. V. Lebedeva (Director of the National Department for the Protection of Maternity and Child Welfare in Soviet Russia) presented a paper on the work being done there. She said that first of all her countrymen regard motherhood as a social function and mothers' and infants' welfare as a task of the State, and secondly, that the woman was always regarded as a force in the process of work. Thus the creche occupied a far more important place in Russian maternity work than in other countries. The legally-secured leave-period for Russian mothers was four months for manual workers and three months for intellectual workers. The institutions in force in the large centres include consultation clinics for infants, toddlers, and pregnant women, tuberculosis and venereal disease dispensaries, feeding centres and milk canteens, and offices for legal consultation and educational patronage. Allowances were granted through insurance offices for the time of pregnancy and lactation and for the necessary accouchement outfit. On Jan. 1st, 1924, there were in Russia 548 creches, 185 children's clinics, 44 mothers' clinics, 107 homes for mother and child, 401 homes for children, and 35 maternity homes. In Moscow a scientific institute of mothers' and infants' welfare had been established to deal with the physiology and pathology, prophylaxis and therapeusis of the mother and child, together with the teaching of physicians, pediatrists, midwives, and nurses. Here 197 doctors and 434 nurses and midwives were working.

Dr. Safieh Ali (Constantinople) said that the maternal morbidity in Turkey was chiefly due to sepsis resulting from lack of adequate nourishment during pregnancy and care during the puerperium. The women were well taken care of during labour, and the midwives' school, opened in 1847, was an excellent one. The first maternity hospital was opened in Stamboul in 1892, and there now existed Red Crescent antenatal polyclinics where expectant mothers were examined and supplied with food where necessary.

Mme. J. Réquin (Paris) divided the causes of maternal morbidity into medico-surgical and social, and gave statistics showing the relative proportion of deaths due to the various causes. She described the preventive work done in France, where there are free antenatal clinics in connexion with a hospital, a laboratory, a venereal disease and a tuberculosis dispensary. She urged the need for coöperation between doctor, midwife, and health visitor in educating women as to the importance of antenatal care. For those women who are delivered at home certain institutions provided advice on hygiene and lent materials for the accouchement, but there was need for more maternity hospitals, and for increased facilities of transport in country districts. The social causes of morbidity Mme. Réquin described as fatigue, unhappiness, and prejudice—i.e., against the unmarried mother, and against lack of luxuries and comfort which leads an increasing number of pregnant women to procure abortion.

Dr. Signe Swensson (Norway) spoke of the importance of diet in the pregnant period, and the greater part of her paper was occupied with the question of the vitamin-content in the artificially-prepared foods of the present day.

Papers by Dr. Hamilton, from the International Committee of the Association of Women in Public Health; by Dr. Wanda Szczawinska, of Warsaw; by Dr. Daisy Robinson (U.S.A.) on the public health and venereal disease aspect of the subject; and by Dr. Sarah Buckley, of Chicago, were also communicated.

CONGRESS OF THE ROYAL SANITARY INSTITUTE.

THE thirty-fifth annual Congress of the Royal Sanitary Institute, held last week at Liverpool, was well attended by some 1250 delegates, many of them from overseas. The delegates included representatives of the medical, engineering, and architectural professions, and many members of health authorities in all parts of the kingdom.

The Inaugural Address.

Lord Salisbury, the President of the Congress, delivered an inaugural address to a large audience in St. George's Hall on the evening of July 14th. He showed that the remarkable progress made in public health matters during the 70 years since Disraeli enunciated his famous aphorism "Sanitas sanitatum, omnia Sanitas," gave no justification for pessimism. Nevertheless, much remained to be done. The back of the housing problem was not yet broken. The corporation of Liverpool had done a great deal. They owed much also to the authors of the Garden City movement. The essentials of a healthy house ought not to be costly. The provision of baths should depend upon the public opinion of the locality. Parlours, too, were rather amenities than essentials, and should only be provided if the occupiers were prepared to pay the extra rent involved. He concluded his address with a note of warning that the pursuit of sanitation and sanitary comforts was not a sufficient aim in itself, and could only be safely practised by a nation which realised that these things, important as they are, are only valuable according as they bring up a race which, governed by the spiritual idea of service, becomes more capable of effort and more equal to the achievement of the work which its world-wide responsibilities demand.

The Health Exhibition.—On July 14th also the Health Exhibition was opened by the Lord Mayor of Liverpool, supported by the mayors of neighbouring boroughs. The exhibition was well arranged in a building well adapted for the purpose, but situated rather far from the general meeting place and the attendance at the exhibition suffered from this fact.

The Sections.

The business of the Congress was conducted at five sessions: (A) Sanitary Science; (B) Engineering and Architecture; (C) Maternity and Child Welfare, including School Hygiene; (D) Personal and Domestic Hygiene; and (E) Industrial Hygiene. There were also seven conferences—namely, of representatives of sanitary authorities, of representatives of port sanitary authorities, of medical officers of health, of engineers and surveyors to sanitary authorities, of veterinary inspectors, of sanitary inspectors, and of health visitors.

Sir William Leishman, in his presidential address to Section A, made a strong plea for closer collaboration between the hygienist and the pathologist. His communication was followed by a discussion on the uses which might be made of the Schick test and immunisation for diphtheria, a valuable paper contributed by Dr. R. A. O'Brien being debated by Dr. H. P. Newsholme and Dr. E. H. R. Harries. The general opinion appeared to be that the staff of fever hospitals ought to be protected by immunisation, and that the method might be usefully adopted for the control of diphtheria in residential and other schools. Several speakers from U.S.A., including Prof. Welsh from Johns Hopkins University, took part in the discussion and showed that immunisation is being practised on a much larger scale in America. It was suggested that in some parts of America the disease is much more fatal than in this country, that the American population is much more ready to submit itself to measures of this kind, and that experience in this country with regard to vaccination does not hold out much prospect of the successful immunisation of the whole population against diphtheria.

The question of education in hygiene and propaganda with regard to V.D. gave rise to an animated discussion in Section A, opened by Dr. I. Feldman and Dr. Winifred Piggott.

The proceedings of the Section of Industrial Hygiene were opened by a valuable address from Dr. T. M. Legge, Senior Medical Inspector of Factories, which was followed by a suggestive paper delivered by Lieut.-Col. F. E. Fremantle, M.P., which we publish in abridged form on p. 200 of this issue of THE LANCET. Both papers showed how little progress has been made with regard to industrial hygiene in this country.

On Thursday, July 17th, there was a crowded gathering at the meeting of Section C on Maternity and Child Welfare to hear the discussion on antenatal clinics. The subject was ably opened by Dr. F. Cook, who was followed by Prof. Louise McIlroy. Unfortunately, the discussion was to be succeeded on the same morning by a discussion on the system of charging for the medical services provided for the maternity and child welfare centres and in the schools. The result was that in the first discussion the speakers were much hurried and there was little opportunity for general discussion. At the meeting of the port sanitary authorities the question of the sanitation of the mercantile marine was dealt with by Dr. W. Hanna and Dr. J. Howard Jones. In the course of the discussion it was shown that the arrangements for the crews leave much to be desired. It was stated that some shipowners were reverting to the old bad type of crews' quarters in the forecastle usual before the war.

Meat Inspection.

The question of meat inspection was discussed by the veterinary inspectors. Mr. H. L. Torrance showed that the illicit dealing in diseased meat carried on in the underworld of the meat trade was very much greater than was generally known and the inference was that it must be very profitable. A resolution was passed expressing the view that public abattoirs should be substituted for private slaughter-houses, so that all animals intended for human food could be submitted to both ante-mortem and post-mortem examination.

At the conference of medical officers of health on the last day Prof. W. S. Lazarus-Barlow put forward a large scheme for dealing with cancer. The scheme included arrangements for following up cases after operation and for the provision of centres for radium and X ray treatment for the whole country. He estimated that for a population of 42 millions £340,000 worth of radium should be available and might be allocated to seven centres, and that 14 fully equipped X ray centres would be required. It would also be necessary to have some State-aid for bringing the patients to, and treating them at, the centres. He suggested coöperation between the voluntary hospitals and Poor-law infirmaries to provide the necessary accommodation, and further stated that, on his advice, a scheme on these lines had already been started in one of the great dominions overseas. The mother country, therefore, should not lag behind.

The general arrangements for the Congress were, on the whole, very good.

THE LANCET LUNCHEON
TO
OVERSEAS MEDICAL REPRESENTATIVES.

ON Thursday, July 17th, in the Oak Room of the Hotel Victoria, London, a luncheon was given by THE LANCET to the Overseas Medical Representatives now on a visit to this country in connexion with the British Empire Exhibition. Some sixty guests accepted the invitation.

After the loyal toasts had been duly honoured, Sir Ernest Hodder-Williams, C.V.O., the Chairman of THE LANCET, who presided, welcomed the guests. He said that though on occasion he had been compelled to take unpleasant prescriptions from doctors he was not on this occasion going to get some of his own back on doctors by making a long speech to them. THE LANCET was delighted to show their welcome to the overseas members of the medical profession, and he and the staff were glad to have the honour of making personal acquaintance with a large group. THE LANCET had recently celebrated its centenary, and in the hundred years which had thus been commemorated there was nothing more remarkable than the way in which there had come into being a real unity of work and purpose in medicine among the English-speaking peoples, a constant interchange of views and works to the immense benefit of medicine and of mankind. The overseas dominions had given to the old country of their very best, while we on our part had certainly reciprocated. British medicine recognises no sundering seas. Science has no nationality; knowledge, as Pasteur said, "is the patrimony of humanity, though, at the same time, it should be the highest personification of nationality. Let us strive then in the pacific field of science for the pre-eminence of our several countries." The record of these strivings, of success, and of failure which is so often the precursor of success, is to be found in the pages of the paper which he represented, and more and more space will be devoted in the years to come to the record of the attainments of our overseas visitors.

Sir Squire Sprigge, the Editor, who endorsed the Chairman's words of welcome, regretted that duty had prevented the gathering from being larger, so many who had responded to the call of Imperial celebration by presence in the mother country having had to return home; but even in these circumstances the quality of the response to the invitation was significant. As an example of the spread of medical knowledge and increased facilities of inter-communication, he pointed out that in a copy of The Lancet dated a little more than 100 years ago he found the first foreign communication: it was about half a column in length and had taken seven days to travel about 240 miles. Its appearance was considered by the editorial staff of that day to be a great event, for it was referred to at the beginning and in the middle of the paper and again commented upon in the following week. That was foreign correspondence in 1824. And now the publication of foreign correspondence from almost every part of the globe was a weekly incident. Although such effort was common to any newspaper which attempted in the smallest way to mirror the modern interchange of scientific thought, it could not be done if it were not for the extraordinary goodwill of the people at the peripheral centres towards the people at the old centre. Just as we send our best to the overseas centres, so they on their part send their best to us, and only from that kind of coöperation could such papers as the *Journal of the American Medical Association*, the *British Medical Journal*, or The Lancet be produced.

In reply, Dr. L. M. McKillop expressed on behalf of the guests his extreme pleasure at the way in which they had been honoured. They had come many miles on a journey that had sometimes been wearisome, but among the many compensations they had received none had given more pleasure than the magnificent luncheon which The Lancet had provided, an evidence of kind thought for which they would ever feel indebted. The Lancet had fostered the feelings of good fellowship among members of the medical profession for over 100 years.

Dr. Edward H. Fyffe, who also responded on behalf of the guests, confirmed the sentiments of the previous speaker and said that the overseas visitors would go back to their homes with very kindly feelings for the way they had been received in the mother country.

The Hon. P. C. Larkin, High Commissioner for Canada, having proposed a vote of thanks to the Chairman, who briefly responded, the gathering broke up with many expressions between the guests of the goodwill and fellowship which medical science has engendered among its votaries.

Among those present were:—

Dr. Margaret Balfour, Dr. A. M. Begg, Sir John Rose Bradford, Dr. A. J. Spiller Brandon, Dr. Caroline S. Brown, Sir Bruce Bruce-Porter, Dr. Harry Campbell, Dr. A. J P. Chapman, Dr. N. H. Club-Wala, Dr. J. J. Costello, Dr. Mary Crawfurd, Lord Dawson of Penn, Dr. R. W. Edgar, Mr. D. Eley, Dr. W. W. Fairfax, Dr. E. Gordon Fleming, Dr. Edward H. Fyffe, Dr. F. le M. Grasset, Sir William Hale-White, Dr. F. D. Hayman, Dr. A. T. Hobbs, Sir Ernest Hodder-Williams, Mr. Ralph Hodder-Williams, Dr. M. W. Kaplan, Mr. J. H. Kelly, Dr. Marguerite Kettle, Dr. C. A. King, Dr. J. H. W. Laing, Hon. P. C. Larkin, Dr. Joseph McAndrew, Dr. L. M. McKillop, Dr. P. McRitchie, Dr. R. H. Marten, Dr. J. L. Meagher, Dr. L. J. Middleton, Dr. M. Minde, Dr. G. H. Morrison, Sir George Newman, Dr. J. A. Nolan, Dr. W. Paisley, Dr. Henry S. Phillips, Dr. Isabella Phillips, Dr. Kate Platt, Dr. M. P. Reddington, Dr. Irvine K. Reid, Dr. G. W. Richardson, Dr. J. I. Rowan, Mr. E. M. Ryder, Mr. R. E. Sare, Dr. Barnet Solomons, Dr. V. E. Sorapure, Sir Squire Sprigge, Dr. H. Lawrence Stokes, Dr. Charles Sutherland, Dr. J. T. Tait, Captain Oscar V. Viner, and Mr. A. E. Mortimer Woolf.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

The ninety-second annual meeting of the British Medical Association opened at Bradford on Friday, July 18th, when the Representative Body met at 10 A.M. in the examination hall of the Technical College to consider the medico-political questions of the year. Dr. R. Wallace Henry occupied the chair for the last time.

Municipal Welcome.

Early in the session the Lord Mayor of Bradford, Alderman H. M. Trotter, accompanied by the town clerk, Mr. N. L. Fleming, paid a visit to the meeting in order to welcome the Association on its first visit to Bradford. They were introduced by Mr. J. Basil Hall, M.Ch. Camb., President-Elect, who acknowledged the kindness and consideration of the civic officials at every stage in the preparations for the meeting; a real spirit of hospitality, he said, had pervaded the whole community. Alderman Trotter invited the Association to inspect the municipal undertakings—hospital and clinics—of which Bradford was justly proud, and spoke of the urgent need for more medical men in the civic councils of the country. Dr. Henry replied that the Association would examine with peculiar pleasure the municipal experiments in medical administration which had been so highly lauded and so severely criticised. The hon. local general secretary, Dr. W. N. West Watson, also welcomed the Association.

Representative Meeting.

Friday, July 18th.

After some formal business and the reading of apologies of absence, Lieut.-Col. F. O'Kinealy, I.M.S., was elected to represent the Indian Medical Service on the B.M.A. Council for 1924–27. Dr. G. E. Haslip, retiring on account of ill-health from the office of treasurer to the Association (1916–24), was elected a vice-president. Later on in the session Mr. N. Bishop Harman was elected treasurer in his place. Dr. F. G. Thomson, of Bath, was elected President of the Association for the year 1925-26, and the annual meeting of 1926 was fixed for Nottingham. Speaking to the financial sections of the report, Dr. R. A. Bolam, acting treasurer, gave an account of the Association's new house which it was proposed to enter without ceremony in March, 1925, the formal opening to take place a few days before the annual meeting at Bath later in the year. While a few minds were still hesitant about the financial commitment, the majority were evidently proud of the possession of a building with a noble hall and adequate space for all the activities of the Association. The notable services of Dr. Bolam as chairman of the B.M.A. Council in securing the new building were warmly acknowledged, as also those of Mr. L. Ferris-Scott, F.C.A., the financial secretary.

Medico-Political Matters.

Mr. E. B. Turner, chairman of the Medico-Political and Parliamentary Committee, moving the adoption of this section of the report, spoke of the lapse of the Dangerous Drugs Regulations in so far as they were irksome or deleterious to medical practitioners. The fees offered for medical examination of recruits (Navy 4s. per head, Air Force and Army 2*s.* 6*d.* per head) were totally inadequate, and opinion to that effect had been conveyed to the authorities. The fees paid to Admiralty surgeons and agents had been reduced in November last (consultation at surgery from 3*s.* 6*d.* to 3*s.* 3*d.*) and protest had proved unavailing. Fees paid to civilian medical practitioners for attendance on soldiers on furlough had undergone similar reduction; in the opinion of the Army Council protest would be unavailing so long as there is no disposition shown by members of the profession to decline to do the work at current rates. On the other hand, the concessions made by the Home Office, in a circular to chief constables, in regard to fees to doctors called to street emergencies were of a more satisfactory character. Salaries of Home Office medical officers compared very unfavourably with those of the Ministry of Health, and it was the policy of the Association to get all this medical work as well as that of the Board of Education transferred, as had been foreshadowed when the Ministry of Health was instituted to this department.

Referring to the approaching election by the Representative Body of direct representatives to the General Medical Council, Mr. Turner regarded the constituency as not large enough for a useful "P.R." vote. Put to the meeting it was decided to elect the four representatives by the block or "first past the post" system.

Use of Opium by Midwives.

On a motion by Croydon, protest was raised once again against the use of opium by midwives. Mr. Turner pointed out that three times the protest had been met by the Central Midwives Board with a blank refusal, although the use of pituitrin by midwives had been prohibited. Croydon when challenged was unwilling to bring forward any direct evidence of improper use of opium by midwives.

Consultation between Medical Witnesses.

The Representative Body had resolved in 1923 that it is desirable for medical men who may be called as witnesses in legal cases (especially under the Workmen's Compensation Act) to consult with each other before the case is heard so that they may, if possible, agree upon facts. This principle was, indeed, approved as long ago as 1905. A motion was proposed by Dr. G. H. Lowe (Cleveland):—

> That wherever possible, in cases which depend on medical evidence alone, there should be a consultation between the medical witness on both sides with a view to agreement on facts, and that such cases should be settled by an arbitrator and not by a judge in open court.

The question was asked: Does any case depend on medical evidence alone? and doubt was expressed as to the expediency (if practicable) of withdrawing cases from public trial. The motion was lost heavily.

Fees Paid to Doctors called in by Midwives.

No fee is provided in the present scale for such special service as induction of premature labour, and representation has been made to the Ministry of Health. A motion by Lewes and East Grinstead proposed:—

> That the Council be requested to approach the Ministry of Health with the object of revising the scale of fees which are paid to doctors called in on the advice of midwives, as this meeting considers the fees to be inadequate.

Dr. H. B. Brackenbury said that, although the subcommittee had never admitted that the present fees were adequate, a fair bargain had on the whole been struck. In Lancashire, it was pointed out, the scale corresponded with the fees charged to private patients under similar social conditions, and the scale was no more than the guarantee of payment if the medical man did not charge and obtain payment on his own scale. The motion was withdrawn by consent.

Approval was given to a special report of the Society of M.O.H.'s on the Midwives Act, subject to the ninth paragraph, reading:

> A midwife who acts only as a monthly nurse should be allowed freedom from supervision under the rules of the C.M.B. if she be a fully trained nurse.

Fees for Ambulance Lectures.

It was proposed by Mr. Turner, in regard to first-aid equipment in factories and the instruction how it should be used, that a fee of not less than £1 1s. per lecture be demanded. The British Red Cross Society's course was stated to be nine lectures of one and a half hours each (one hour lecture, half an hour practical), that of St. John Ambulance Association, six lectures of one hour each. After discussion the motion was carried in the following form:—

> That when a course of ambulance lectures is desired in order to fulfil or supplement the requirements laid down in Section 29 of the Workmen's Compensation Act, 1923, the fee should be a minimum of £1 1s. per lecture, with an additional fee of 1s. per head for every member of the class in excess of 21.

On the proposal of Dr. W. F. Dearden (Manchester) it was referred to the B.M.A. Council to consider whether under the Act arrangements should be made for redrafting the ambulance requirements and for continuous medical supervision of the equipment and working. On the evidence of inspectors the boxes were found to be unsatisfactory in 43 per cent. of cases.

A Benevolent Fund.

The Representative Meeting of 1923 acquiesced in the statement that "the charitable funds are a disgrace to our profession," but did not then proceed to definite action. Two motions, by South Essex and by Manchester, combined to the effect:—

> That it be an instruction to the Council to examine and report on medical benevolent funds, including the possibility of a British Medical Association Benevolent Fund.

Dr. F. Rees said that existing benevolent funds were managed by the hierarchy of the profession, and that an association of general practitioners could manage better. The R.M.B.F. had had, it was true, a large accession of membership during the past year owing to the Portsmouth discussion—600 new members with £1000 increased income; and the B.M.A. subscriptions to benevolence had increased by some £300. But as Dr. J. T. D'Ewart said, there was still little consolation for the man who was down on his luck except to "get buried quick." In its divisions the B.M.A. possessed all the machinery for collecting and administering benevolent funds. Dr. Bolam indicated that it would require about 10s. a head annually to produce even the present meagre result. That money must either come voluntarily out of the pockets of members or from an enhanced subscription. The motion to instruct the Council was carried by a large majority.

Legal Liability in Medical Certification.

The protection of medical men from litigation as a result of honest certification claimed the attention of the meeting from various aspects. Dr. David Roxburgh (Marylebone) proposed and Dr. W. J. Leighton (Preston) seconded a motion:—

> (i.) That the Council of the Association be instructed to take such steps as shall cause the liability of medical practitioners to actions at law for damages for issuing bona-fide certificates to cease; (ii.) that the methods employed to attain that end may include continuously repeated advice to all practitioners not to issue certificates except on evidence which is certain to convince a judge and jury—for example, that a patient suffering from homicidal mania or suicidal tendencies must first have succeeded in satisfying his ambition, or that a patient suffering from small-pox must first have communicated the disease to another person, &c.; and (iii.) that alternatively the law shall at once be so modified as to recognise that certain certificates are issued in the public interest, which includes that of the patient; that practitioners issuing them are public servants; that the public authorities accept the whole consequences of their errors, that actions shall only lie against the public authority, and that—if it be required—additional powers be given to the General Medical Council to deal with medical practitioners.

Dr. Roxburgh believed that the institution of proceedings against a medical man for the expression of honest opinion was no part of statutory law, he deprecated the infliction of what amounted to a fine for issuing bona-fide opinions, and he proposed his motion as a means of driving home to the public that if the medical certifier is to be tried by a jury, the evidence shall be such as will satisfy the jury. He dwelt on the psychological stress of the atmosphere in such trials and its effect on judge and jury. The motion as framed when put to the meeting was lost by a large majority.

at the same time, it should be the highest personification of nationality. Let us strive then in the pacific field of science for the pre-eminence of our several countries." The record of these strivings, of success, and of failure which is so often the precursor of success, is to be found in the pages of the paper which he represented, and more and more space will be devoted in the years to come to the record of the attainments of our overseas visitors.

Sir Squire Sprigge, the Editor, who endorsed the Chairman's words of welcome, regretted that duty had prevented the gathering from being larger, so many who had responded to the call of Imperial celebration by presence in the mother country having had to return home; but even in these circumstances the quality of the response to the invitation was significant. As an example of the spread of medical knowledge and increased facilities of inter-communication, he pointed out that in a copy of THE LANCET dated a little more than 100 years ago he found the first foreign communication: it was about half a column in length and had taken seven days to travel about 240 miles. Its appearance was considered by the editorial staff of that day to be a great event, for it was referred to at the beginning and in the middle of the paper and again commented upon in the following week. That was foreign correspondence in 1824. And now the publication of foreign correspondence from almost every part of the globe was a weekly incident. Although such effort was common to any newspaper which attempted in the smallest way to mirror the modern interchange of scientific thought, it could not be done if it were not for the extraordinary goodwill of the people at the peripheral centres towards the people at the old centre. Just as we send our best to the overseas centres, so they on their part send their best to us, and only from that kind of coöperation could such papers as the *Journal of the American Medical Association*, the *British Medical Journal*, or THE LANCET be produced.

In reply, Dr. L. M. McKillop expressed on behalf of the guests his extreme pleasure at the way in which they had been honoured. They had come many miles on a journey that had sometimes been wearisome, but among the many compensations they had received none had given more pleasure than the magnificent luncheon which THE LANCET had provided, an evidence of kind thought for which they would ever feel indebted. THE LANCET had fostered the feelings of good fellowship among members of the medical profession for over 100 years.

Dr. Edward H. Fyffe, who also responded on behalf of the guests, confirmed the sentiments of the previous speaker and said that the overseas visitors would go back to their homes with very kindly feelings for the way they had been received in the mother country.

The Hon. P. C. Larkin, High Commissioner for Canada, having proposed a vote of thanks to the Chairman, who briefly responded. the gathering broke up with many expressions between the guests of the goodwill and fellowship which medical science has engendered among its votaries.

Among those present were :—

Dr. Margaret Balfour, Dr. A. M. Begg, Sir John Rose Bradford, Dr. A. J. Spiller Brandon, Dr. Caroline S. Brown, Sir Bruce Bruce-Porter, Dr. Harry Campbell, Dr. A J P. Chapman, Dr. N. H. Club-Wala, Dr. J. J. Costello, Dr. Mary Crawfurd, Lord Dawson of Penn, Dr. R. W. Edgar, Mr. D. Eley, Dr. W. W. Fairfax, Dr. E. Gordon Fleming, Dr. Edward H. Fyffe, Dr. F. le M. Grasset, Sir William Hale-White, Dr. F. D. Hayman, Dr. A. T. Hobbs, Sir Ernest Hodder-Williams, Mr. Ralph Hodder-Williams, Dr. M. W. Kaplan, Mr. J. H. Kelly, Dr. Marguerite Kettle, Dr. C. A. King, Dr. J. H. W. Laing, Hon. P. C. Larkin, Dr. Joseph McAndrew, Dr. L. M. McKillop, Dr. P. McRitchie, Dr. R. H. Marten, Dr. J. L. Meagher, Dr. L. J. Middleton, Dr. M. Minde, Dr. G. H. Morrison, Sir George Newman, Dr. J. A. Nolan, Dr. W. Paisley, Dr. Henry S. Phillips, Dr. Isabella Phillips, Dr. Kate Platt, Dr. M. P. Reddington, Dr. Irvine K. Reid, Dr. G. W. Richardson, Dr. J. I. Rowan, Mr. E. M. Ryder, Mr. R. E. Sare, Dr. Barnet Solomons, Dr. V. E. Sorapure, Sir Squire Sprigge, Dr. H. Lawrence Stokes, Dr. Charles Sutherland, Dr. J. T. Tait, Captain Oscar V. Viney, and Mr. A. E. Mortimer Woolf.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

THE ninety-second annual meeting of the British Medical Association opened at Bradford on Friday, July 18th, when the Representative Body met at 10 A.M. in the examination hall of the Technical College to consider the medico-political questions of the year. Dr. R. WALLACE HENRY occupied the chair for the last time.

Municipal Welcome.

Early in the session the Lord Mayor of Bradford, Alderman H. M. TROTTER, accompanied by the town clerk, Mr. N. L. FLEMING, paid a visit to the meeting in order to welcome the Association on its first visit to Bradford. They were introduced by Mr. J. BASIL HALL, M.Ch. Camb., President-Elect, who acknowledged the kindness and consideration of the civic officials at every stage in the preparations for the meeting; a real spirit of hospitality, he said, had pervaded the whole community. Alderman Trotter invited the Association to inspect the municipal undertakings—hospital and clinics—of which Bradford was justly proud, and spoke of the urgent need for more medical men in the civic councils of the country. Dr. HENRY replied that the Association would examine with peculiar pleasure the municipal experiments in medical administration which had been so highly lauded and so severely criticised. The hon. local general secretary, Dr. W. N. WEST WATSON, also welcomed the Association.

REPRESENTATIVE MEETING.

FRIDAY, JULY 18TH.

After some formal business and the reading of apologies of absence, Lieut.-Col. F. O'KINEALY, I.M.S., was elected to represent the Indian Medical Service on the B.M.A. Council for 1924–27. Dr. G. E. HASLIP, retiring on account of ill-health from the office of treasurer to the Association (1916–24), was elected a vice-president. Later on in the session Mr. N. BISHOP HARMAN was elected treasurer in his place. Dr. F. G. THOMSON, of Bath, was elected President of the Association for the year 1925-26, and the annual meeting of 1926 was fixed for Nottingham. Speaking to the financial sections of the report, Dr. R. A. BOLAM, acting treasurer, gave an account of the Association's new house which it was proposed to enter without ceremony in March, 1925, the formal opening to take place a few days before the annual meeting at Bath later in the year. While a few minds were still hesitant about the financial commitment, the majority were evidently proud of the possession of a building with a noble hall and adequate space for all the activities of the Association. The notable services of Dr. Bolam as chairman of the B.M.A. Council in securing the new building were warmly acknowledged, as also those of Mr. L. FERRIS-SCOTT, F.C.A., the financial secretary.

MEDICO-POLITICAL MATTERS.

Mr. E. B. TURNER, chairman of the Medico-Political and Parliamentary Committee, moving the adoption of this section of the report, spoke of the lapse of the Dangerous Drugs Regulations in so far as they were irksome or deleterious to medical practitioners. The fees offered for medical examination of recruits (Navy 1*s*. per head, Air Force and Army 2*s*. 6*d*. per head) were totally inadequate, and opinion to that effect had been conveyed to the authorities. The fees paid to Admiralty surgeons and agents had been reduced in November last (consultation at surgery from 3*s*. 6*d*. to 3*s*. 3*d*.) and protest had proved unavailing. Fees paid to civilian medical practitioners for attendance on soldiers on furlough had undergone similar reduction; in the opinion of the Army Council protest would be unavailing so long as there is no disposition shown by members of the profession to decline to do the work at current rates. On the other hand, the

SATURDAY, JULY 19TH.

ORGANISATION OF THE ASSOCIATION.

On a motion to approve that part of the report of the Council dealing with organisation, Dr. S. **MORTON MACKENZIE**, chairman of the Organisation Committee, gave a brief account of the present position of the Association. The total membership to date was, he said, 27,533, being the highest number yet recorded. Last year nearly 2800 new members joined, attracted, he thought, by the proved willingness of the Association to take up anything to help its members. The Handbook for Recently Qualified Medical Practitioners was proving useful in recruiting, and was being distributed gratis to those attending the social meetings of welcome at teaching centres. At Newcastle-on-Tyne during the last two years every newly qualified man had joined. Prizes for essays on clinical or pathological subjects were being offered to final-year students, and he thanked the examiners—Prof. G. L. Gulland (Edinburgh), Prof. A. J. Hall (Sheffield), Sir William Hale-White, and Sir H. Rolleston (London)—for their services.

South African Branches.

In South Africa, although a referendum of the whole profession had shown a majority of 190 out of 1288 voting in favour of the formation of a South African Medical Association affiliated to the B.M.A., a second referendum of members of the South African branches of the Association resulted in seven out of the ten branches (with a total membership of 700) voting against the formation of a new association. The need there was for an efficient medical organising secretary and the Association was offering to pay half the expense over a period of three years. Dr. L. G. **IRVINE** (Witwatersrand) expressed the satisfaction of that branch at the action of the B.M.A., which might justly be called an *imperial* medical association.

Approving Signatures for Membership Applications.

A motion was brought forward by Darlington disapproving of the Council's suggestion to dispense with approving signatures on forms of application for membership, and affirming that such signatures are a safeguard against the division or branch being exploited by individuals unworthy of becoming members. An interesting discussion ensued, it being contended that an approving signature is no safeguard, for the undesirable member is apt to introduce a rather more undesirable, and that the effective retort is to put the worst member of the branch on the executive and make him chairman thereof. The meeting turned down the resolution on the assurance that every divisional secretary should be ex-officio member of the branch council which admits applicants

A Woman Member of Council.

Croydon proposed that of the eight members of the B.M.A. Council elected by the Representative Body at least one shall be a woman. Dr. **HAWTHORNE** quaintly suggested that the proposal was out of order as the articles of association prohibited the conferring of privilege on any individual member or group of members, but the chairman allowed discussion to proceed. Dr. **CHRISTINE MURRELL**, a duly elected member of the Council, stated on behalf of the women members of the Association that they recognised that the Association was a democracy with no sex bar and that preferred to stand without privilege. There were in fact three women present as representatives of divisions or branches. Her statement was received with applause, and the motion was withdrawn by consent.

INDIVIDUAL DEFENCE.

Last year a proposal by Warrington that the individual defence of members in professional matters should be one of the functions of the Association was lost by a large majority. This year the question was again raised by motions from Warrington and Manchester which were combined for discussion into the clear issue:

That the B.M.A. Council be instructed to formulate a scheme for the medical defence of individual members of the Association either by itself or in coöperation with existing bodies.

Dr. J. S. **MANSON**, who again opened the discussion, described it as a recurrent question, never quite decided. Less than half the members of the Association were, he said, within the professional defence societies, although no doubt there were others assured in commercial companies. These presumably were acting for profit on some actuarial basis, and he saw no reason why the B.M.A. should not reap this harvest for itself. There was still scope, for whereas in 1912 63 per cent. of the numbers on the Medical Register were members of the Association, the proportion in 1923 was only 54·7 per cent. Need was greater, for even "token" payment to hospital staffs deprived them of their immunity from attack as honorary officers, and a proper defence department of the Association was needed to deal with chiropractors et hoc genus omne. To pass this motion would, he thought, be a fitting celebration of the twenty-first birthday of the new constitution. Dr. A. **LYNDON** (Guildford) asked, where are you going to draw your numbers for the new scheme? Excepting overseas members, who were considered ineligible for any existing scheme of individual defence, the 18,500 or so members of the Association equalled roughly the membership of the three professional defence societies. The proposal could only be justified on commercial grounds and the Association had no relevant experience behind it. He informed the meeting that the Medical Defence Union was already active in prosecuting unqualified practitioners. Dr. P. **MACDONALD** (York), admitting that defence was now efficient, argued that the Association could not afford to remain outside a matter so important to its membership. Dr. E. R. **FOTHERGILL** (Brighton) exhorted the meeting not to worry, but to get into a position to avoid appeals for help from members who had got into scrapes. Prestige suffered from such recurrent events. Even in the successfully defended action the practitioner found himself a couple of hundred pounds out of pocket. There was sufficient scope for defence in scooping up all the young men entering the profession. Dr. **BRACKENBURY**, expressing sympathy with the proposal, questioned whether it was good business at the moment. The National Union of Teachers, whose defence scheme had been cited, was, he said, preponderatingly concerned not with defence against individuals but against public bodies, and that the Association was already doing. Dr. **MORTON MACKENZIE** repeated the well-worn but weighty arguments against the proposal—it was too late in the day to begin, the opportunity had been allowed to slip, opposition from existing defence organisations was uncompromising, overseas assurance was impracticable, the proposal would not increase membership, rather the reverse: finally (a new point) the Association would lose its right of proceeding at the General Medical Council until the individual had been turned out of membership—a lengthy process. Dr. **MANSON** replied, and the motion being put was rejected by 76 votes to 58.

SCIENTIFIC SUBJECTS.

Mr. H. S. **SOUTTAR**, chairman of the Science Committee, in asking for approval of his section of the Council's report, remarked on the brilliant work presented for the scholarships which could have been allocated three times over. The Sir Charles Hastings Clinical Prize was offered with the object of stimulating systematic observation, research, and record in general practice, the proper sphere of research being always among a practitioner's own patients. On the motion of Sheffield the Council agreed favourably to consider the award of supplementary prizes in the event of more than one essay of merit being sent in. Dr. H. **CAIGER** mentioned the cause of appendicitis as a fitting object of general practitioner

CERTIFICATES UNDER THE LUNACY ACTS.

Dr. C. O. **HAWTHORNE** (Marylebone) then proposed and Dr. F. W. **GOODBODY** (Marylebone) seconded a motion to the effect:—

> That the provision of a certificate under the Lunacy Acts by a qualified medical practitioner should be an act having the legal status of testimony given by a witness in a court of law, and should not render the practitioner liable either to any civil action or to any criminal charge, except in so far as the certificate may be shown to contain statements of essential importance which are proved to be inaccurate and to have been made with a wilful and deliberate intention; to deceive.

Dr. Hawthorne said that the responsibility of certifying was accepted by the medical profession largely in the public interest. It was a heavy and, to many of them, an obnoxious responsibility, and the great majority of the medical profession would be glad to be relieved of it altogether. As the law stood the medical profession was the sole agency standing between the community and the person of unsound mind, and the sole agency by which persons of unsound mind were protected against themselves. Hence, though there was no legal compulsion on the medical practitioner to sign the certificate, the moral pressure in the great majority of cases was such that the practitioner felt himself, in the interests of the community and the patient, and for the credit of the profession, morally compelled to accept the responsibility attaching to the signature of a lunacy certificate.

The law recognised that the signing of the certificate was a public service by providing a certain measure of protection for the practitioner who signed it. Thus no action by a patient against a certifying practitioner relative to the certificate could succeed if the practitioner was able to show that, in the words of the Act of Parliament, he had acted "in good faith and with reasonable care." More than that, if an action was brought, the judge of the High Court would bring the proceedings to a prompt conclusion if the practitioner could satisfy the Court that there was no ground whatever for the suggestion that he had failed to act in good faith and with reasonable care. Dr. Hawthorne said that those two provisions formed a measure of protection of very great value, and were appreciated by the medical profession. But they were not adequate, because they left it still possible for an action to be begun against a practitioner, and, if there were some verbal or technical flaw either in the certificate or in any other part of the proceedings, the case might be forced into court, and the practitioner might be put to the expense, annoyance, and strain which were always involved in legal proceedings. In a word, no one signed a lunacy certificate without having before his eyes the fear that the signature might bring on him the penalty for an illegal action.

Partial Protection to be made Complete.

"My suggestion," said Dr. Hawthorne, "is that the protection which is now partial shall be made complete, and that the medical practitioner shall be placed in the same position as a witness who gives testimony in a court of justice. That is to say, for what he does in his capacity as a certifying practitioner he shall not be exposed to the chance of a legal action."

It might be urged that it was in the public interest that medical practitioners should be encouraged, when necessity demanded it, to sign these certificates. He submitted also that in signing such a certificate the medical practitioner, as a matter of fact, was only acting the part of a witness. He was giving evidence both of fact and of opinion before a judicial authority, and it was open to the judicial authority either to accept the evidence or to reject it, or to determine that he would not act until after further inquiries. "That is to say," said Dr. Hawthorne, "the voice which sends the patient into a lunatic asylum is the voice of the law, and all the medical practitioner does in connexion with the transaction is to give evidence of fact and to express an opinion." He went on to point out that the judicial authority who took part in the proceedings was completely protected. What he did or abstained from doing could not possibly be challenged by the person who by his signature was sent to a lunatic asylum. If the judicial authority enjoyed complete immunity from legal challenge surely the medical authority should have the same measure of protection.

The Solicitor's View.

Mr. W. E. **HEMPSON**, solicitor to the Association, congratulated Dr. Hawthorne on his clear and accurate exposition of the law. In the last 30 years he had had on many occasions to make use of Section 330 of the Act, which was the protective section to which Dr. Hawthorne had referred. He had found that when an action had begun in the courts and had proceeded up to a certain point, there was a disinclination on the part of the Master in Chambers, before whom the matter went in the first instance, and on the part of the judge, to whom appeal could be made, to dismiss that action if there was the slightest possibility of the plaintiff succeeding in it. If, he said, you had the Master against you in the first instance, even though you carried it to the Court of Appeal, you had very great difficulty. What Dr. Hawthorne wanted, apparently, was that no action should be permitted to be raised without official authority to that end. There were certain actions at law which could not be begun without the fiat of the Attorney-General, and it seemed to him that this would be a way of dealing with this question. Facts and affidavits would be supplied, and it would be in the power of the Attorney-General to refuse his fiat, in which case no action could be brought; or the fiat might be granted if there were circumstances to which the last part of the resolution referred. At present any litigant who could get a solicitor to act for him could go to the courts and issue his writ, and thus take the action up to the point at which the protective section for the dismissal of the action was reached. Dr. Hawthorne, he took it, wanted the matter to be put on some such footing as this: that unless some element as that alluded to in the last part of the resolution was shown to exist, the action could not be issued nor the writ set in motion.

The Question of Negligence.

Dr. **BRACKENBURY** drew attention to the question of negligence. What about the case, he asked, where a doctor had so neglected his duty as to make only a perfunctory examination—where he had been negligent in getting the information on which to found the certificate? The statement in the certificate might be inaccurate, but might be bona fide. The resolution, it seemed to him, would allow the negligent doctor to get off scot-free.

Mr. **HEMPSON** said he thought that Dr. Hawthorne was aiming at the highest he could get. He thought it very probable that they would have to accept less. Of course, if they got a change on the lines of Dr. Hawthorne's resolution the question raised by Dr. Brackenbury would arise. What they wanted was a change in the law as near Dr. Hawthorne's proposals as they could get, with modifications to provide for the point raised by Dr. Brackenbury.

Mr. E. B. **TURNER** expressed the hope that one of the duties of the committee of the B.M.A. Council which was dealing with this matter would be the preparation of evidence to place before the Royal Commission.

Dr. **HAWTHORNE**, in replying, suggested that negligence was a mere spectre. It was unthinkable that both doctors signing a certificate should fail to describe accurately the things they had seen and heard.

The resolution on being put to the meeting was agreed to with unanimity and enthusiasm, and the B.M.A. Council was asked to consider the question of preparing evidence to lay before the Royal Commission.

SATURDAY, JULY 19TH.

ORGANISATION OF THE ASSOCIATION.

On a motion to approve that part of the report of the Council dealing with organisation, Dr. S. **MORTON MACKENZIE**, chairman of the Organisation Committee, gave a brief account of the present position of the Association. The total membership to date was, he said, 27,533, being the highest number yet recorded. Last year nearly 2800 new members joined, attracted, he thought, by the proved willingness of the Association to take up anything to help its members. The Handbook for Recently Qualified Medical Practitioners was proving useful in recruiting, and was being distributed gratis to those attending the social meetings of welcome at teaching centres. At Newcastle-on-Tyne during the last two years every newly qualified man had joined. Prizes for essays on clinical or pathological subjects were being offered to final-year students, and he thanked the examiners—Prof. G. L. Gulland (Edinburgh), Prof. A. J. Hall (Sheffield), Sir William Hale-White, and Sir H. Rolleston (London)—for their services.

South African Branches.

In South Africa, although a referendum of the whole profession had shown a majority of 190 out of 1288 voting in favour of the formation of a South African Medical Association affiliated to the B.M.A., a second referendum of members of the South African branches of the Association resulted in seven out of the ten branches (with a total membership of 700) voting against the formation of a new association. The need there was for an efficient medical organising secretary and the Association was offering to pay half the expense over a period of three years. Dr. L. G. **IRVINE** (Witwatersrand) expressed the satisfaction of that branch at the action of the B.M.A., which might justly be called an *imperial* medical association.

Approving Signatures for Membership Applications.

A motion was brought forward by Darlington disapproving of the Council's suggestion to dispense with approving signatures on forms of application for membership, and affirming that such signatures are a safeguard against the division or branch being exploited by individuals unworthy of becoming members. An interesting discussion ensued, it being contended that an approving signature is no safeguard, for the undesirable member is apt to introduce a rather more undesirable, and that the effective retort is to put the worst member of the branch on the executive and make him chairman thereof. The meeting turned down the resolution on the assurance that every divisional secretary should be ex-officio member of the branch council which admits applicants

A Woman Member of Council.

Croydon proposed that of the eight members of the B.M.A. Council elected by the Representative Body at least one shall be a woman. Dr. **HAWTHORNE** quaintly suggested that the proposal was out of order as the articles of association prohibited the conferring of privilege on any individual member or group of members, but the chairman allowed discussion to proceed. Dr. **CHRISTINE MURRELL**, a duly elected member of the Council, stated on behalf of the women members of the Association that they recognised that the Association was a democracy with no sex bar and that preferred to stand without privilege. There were in fact three women present as representatives of divisions or branches. Her statement was received with applause, and the motion was withdrawn by consent.

INDIVIDUAL DEFENCE.

Last year a proposal by Warrington that the individual defence of members in professional matters should be one of the functions of the Association was lost by a large majority. This year the question was again raised by motions from Warrington and Manchester which were combined for discussion into the clear issue:

That the B.M.A. Council be instructed to formulate a scheme for the medical defence of individual members of the Association either by itself or in coöperation with existing bodies.

Dr. J. S. **MANSON**, who again opened the discussion, described it as a recurrent question, never quite decided. Less than half the members of the Association were, he said, within the professional defence societies, although no doubt there were others assured in commercial companies. These presumably were acting for profit on some actuarial basis, and he saw no reason why the B.M.A. should not reap this harvest for itself. There was still scope, for whereas in 1912 63 per cent. of the numbers on the Medical Register were members of the Association, the proportion in 1923 was only 54·7 per cent. Need was greater, for even "token" payment to hospital staffs deprived them of their immunity from attack as honorary officers, and a proper defence department of the Association was needed to deal with chiropractors et hoc genus omne. To pass this motion would, he thought, be a fitting celebration of the twenty-first birthday of the new constitution. Dr. A. **LYNDON** (Guildford) asked, where are you going to draw your numbers for the new scheme? Excepting overseas members, who were considered ineligible for any existing scheme of individual defence, the 18,500 or so members of the Association equalled roughly the membership of the three professional defence societies. The proposal could only be justified on commercial grounds and the Association had no relevant experience behind it. He informed the meeting that the Medical Defence Union was already active in prosecuting unqualified practitioners. Dr. P. **MACDONALD** (York), admitting that defence was now efficient, argued that the Association could not afford to remain outside a matter so important to its membership. Dr. E. R. **FOTHERGILL** (Brighton) exhorted the meeting not to worry, but to get into a position to avoid appeals for help from members who had got into scrapes. Prestige suffered from such recurrent events. Even in the successfully defended action the practitioner found himself a couple of hundred pounds out of pocket. There was sufficient scope for defence in scooping up all the young men entering the profession. Dr. **BRACKENBURY**, expressing sympathy with the proposal, questioned whether it was good business at the moment. The National Union of Teachers, whose defence scheme had been cited, was, he said, preponderatingly concerned not with defence against individuals but against public bodies, and that the Association was already doing. Dr. **MORTON MACKENZIE** repeated the well-worn but weighty arguments against the proposal—it was too late in the day to begin, the opportunity had been allowed to slip, opposition from existing defence organisations was uncompromising, overseas assurance was impracticable, the proposal would not increase membership, rather the reverse: finally (a new point) the Association would lose its right of proceeding at the General Medical Council until the individual had been turned out of membership—a lengthy process. Dr. **MANSON** replied, and the motion being put was rejected by 76 votes to 58.

SCIENTIFIC SUBJECTS.

Mr. H. S. **SOUTTAR**, chairman of the Science Committee, in asking for approval of his section of the Council's report, remarked on the brilliant work presented for the scholarships which could have been allocated three times over. The Sir Charles Hastings Clinical Prize was offered with the object of stimulating systematic observation, research, and record in general practice, the proper sphere of research being always among a practitioner's own patients. On the motion of Sheffield the Council agreed favourably to consider the award of supplementary prizes in the event of more than one essay of merit being sent in. Dr. H. **CAIGER** mentioned the cause of appendicitis as a fitting object of general practitioner research, the disease apparently arising on the contact of a primitive nation with civilisation. Mr. Souttar spoke of the appointment of a special committee to inquire into cardiac disease in childhood, which was really a group research undertaken at the instigation of its originators. He commended the practice to other groups.

National Health Insurance.

In moving the approval of this section of the report Dr. H. B. **Brackenbury**, chairman of the Insurance Acts Committee, described it as a record of familiar matters. A report was being prepared for submission to the Royal Commission, the notice being shorter than expected, for the Committee had to be prepared to submit evidence by Jan. 1st, 1925. If time permitted this interim report would be circulated for discussion by the divisions of the Association.

At the conclusion of the morning session the announcement was made amidst applause of the election of Dr. Brackenbury as chairman of the Representative Body for 1924–25.

Election of Members of Council.

The election of 12 members of Council by grouped representatives was reported as follows: Dr. G. B. Hillman, Dr. I. W. Johnson, Dr. J. W. Bone, Dr. T. Ridley Bailey, Mr. E. B. Turner, Dr. W. Paterson, Dr. C. E. S. Flemming, Dr. S. Morton Mackenzie, Dr. C. E. Douglas, Dr. J. McGregor-Robertson, Dr. R. B. Mahon, Dr. J. Singleton Darling; all being unopposed except Dr. Johnson and Dr. Bailey.

Election of Direct Representatives to the G.M.C.

The election by the Representative Body of four from among its membership for nomination as direct representatives to the General Medical Council resulted in the following being proposed: Dr. R. A. Bolam, Dr. H. B. Brackenbury, Dr. J. A. Macdonald, Sir Jenner Verrall.

Hospital Policy.

An important debate was initiated on the motion of Mr. **Bishop Harman**, who moved a recommendation of the Council that contributions to hospitals either by employers of labour or in the form of massed contributions from employees should be considered as contributions for services rendered.

An amendment proposing that contributions to hospitals for which a return of service was definitely stated should be the only ones from which any payment to the visiting staff should be made led to a long and interesting discussion, which showed the general desire of the representatives to maintain the voluntary policy. The amendment being withdrawn the resolution failed to obtain the necessary two-thirds majority.

Monday, July 21st.

Voluntary Hospitals.

The policy of the Association towards voluntary hospitals was the subject of many resolutions on the agenda which were crystallised by a motion from Mr. **Bishop Harman** to the effect that:—

> "Where the board of a voluntary hospital receives contributions from individuals in return for or in anticipation of treatment the members of the visiting medical staffs should receive recognition of their services, either in the form of an agreed honorarium or by means of a percentage of all such payments being passed into a special fund. Such honorarium or fund can be allocated *in any manner* which the visiting medical staff may determine."

After a long debate on the main resolution and on the vital amendments, Mr. Bishop Harman's motion was carried by a considerable majority.

The Ethics of Advertising.

A report from the Ethical Committee was submitted by Dr. Langdon-Brown, in which was proposed a number of restrictions as regards advertising or alleged advertising by members of the medical profession. The report was adopted with certain reservations. (*To be continued.*)

IMPERIAL CANCER RESEARCH FUND.

ANNUAL REPORT.

THE annual meeting of the Imperial Cancer Research Fund was held at the Examination Hall, Queen-square, London, W.C., on July 23rd. The Duke of Bedford presided. Dr. Sidney Martin, F.R.S., chairman of the executive committee, proposed the adoption of the twenty-second annual report, and said:—

"In proposing the adoption of the annual report it has been the custom for the chairman of the executive committee to give a summary of the report of the Director, but with your permission I shall take a somewhat wider view, and on the basis of the contents of the eighth scientific report[1] I shall survey the study of the varied aspects of the cancer problem under the different scientific disciplines which at present are engaged upon it. And firstly, as the oldest, I shall consider the clinical study of cancer in man. This is represented in the eighth scientific report by the monograph of Dr. Alexander Scott on the paraffin dermatoses and paraffin cancer. The executive committee authorised its inclusion in the report because of its unique features, which are the long-continued, careful observation on a fairly large body of workmen exposed continuously to a peculiar form of chemical irritation known, for a long time, to induce cancer. The acute and chronic skin lesions in workers in crude paraffin are described and figured in a series of beautiful plates made from Dr. Scott's own photographs. The relation of these lesions to the subsequent development of cancer is gone into, on the evidence of the individual histories of the workmen, and the whole body of facts surveyed with a masterly grasp of detail. I need only draw your attention to the absence of any close relation between the intensity of the acute early lesions and the later development of cancer, so that in some individuals only extremely slight indications of skin irritation preceded its development. Another point to be noted is the long number of years, never less than 15–20, after which the disease began. The proportion of the workers in which cancer developed was found to be less than 2 per cent. per annum of those engaged, and Dr. Scott shows that it is mainly in the men engaged in certain stages of the preparation of paraffin oil from shale that these cases occur. On the basis of his findings a very complete and, it may confidently be hoped, effective preventive régime has been instituted by the Scottish Oils Company. It has already reduced the incidence of the acute irritative disturbances in the operatives, but its effect on the occurrence of cancer in them can only be seen after a longer lapse of time.

"The executive committee desire to thank Dr. Archibald Leitch, the director of the Research Department of the Cancer Hospital, for allowing the publication in Dr. Scott's paper of a summary of his results in testing the crude and refined oils supplied by Dr. Scott for their carcinogenic powers on animals. These results confirm the importance of the unrefined oils incriminated by Dr. Scott and show the innocuousness of the refined product. This fact should serve to reassure those who have been using refined paraffin medicinally and may have become alarmed by these reports of the production of paraffin cancer.

"In the domain of experimental pathology there are three papers in the report, two by Dr. B. R. G. Russell and one by Dr. J. A. Murray. Experimental pathology may be regarded as an extension of the methods of clinical study to disease as it occurs in animals under controlled conditions. Dr. Russell's papers deal with the production of sarcoma in mice and rats by the subcutaneous inoculation of tar. These observations emphasise the fundamental unity of the cancer process as it occurs in connective tissues (sarcoma) and in epithelial tissues (carcinoma). Dr.

---

[1] An exhaustive analysis of this valuable report appeared in THE LANCET, Dec. 22nd, 1923, p. 1368.

Murray's paper deals with the meaning of the long period—10 to 20 years in man, 5 to 12 months in mice—during which cancer-producing agents must act before the disease sets in, and the paradoxical result that once an animal has become cancerous there is an apparent incapability to react anew with cancer development to fresh applications of tar to another part of the body. These observations illuminate the rarity of multiple primary cancer. The space devoted to histological details in these papers is merely an expression of the importance of the microscopic control which enters at every stage of what is essentially a clinical or biological study of new growths.

“ Dr. A. M. Begg's paper on dissemination in tar cancer belongs more strictly to the province of pathological histology. It is entirely descriptive, and deals with peculiarities in the mode of spread of the epithelioma, particularly along the sheaths of the nerves.

“ Experimental cytology is represented by the work of Dr. A. H. Drew on tissue culture. His work clears up to a great extent the hitherto enigmatical departures from the normal histological picture met with in malignant new growths, showing how this phenomenon can be duplicated in normal tissues, or, on the other hand, how atypical undifferentiated malignant new growths can be made to assume the normal form without loss of their fundamental malignant characters. He has also shown the close relationship between the processes of growth in malignant cells and those responsible for repair of injury.

“ The remaining papers are biochemical in nature. Biochemical investigations are of two kinds: those which apply the methods and reactions of chemistry to the study of the behaviour of living organisms, and those in which, for want of test-tube reactions, the reactions of living organisms are used to demonstrate the presence or absence of chemically active substances or to elucidate their rôle in the animal economy. Dr. Russell's papers on carbohydrate metabolism of normal and cancer cells belong to the former category; Dr. W. Cramer's work on vitamins to the latter. Dr. Russell's investigations, which grew out of a study of cell respiration, have led to the discovery of certain sugar reactions (analogous to those used in the separation of nearly related bacterial species) which are apparently peculiar to cancer cells. They are being made the starting-point of chemotherapeutic experiments. Dr. Cramer's vitamin work deals objectively with an aspect of cancer growth, which has led to a great deal of loose speculation. He shows that when put to the test of direct experiment, no degree of vitamin deficiency compatible with life has any effect on malignant proliferation.

“ From this survey you can see that the work in our laboratory embraces a very comprehensive series of investigations touching varied aspects of the cancer problem, all of them of fundamental importance. The achievements of the past warrant us in meeting the future with sober optimism, and give me confidence in recommending to you the adoption of the twenty-second annual report.”

Sir John Bland-Sutton, F.R.C.S., seconded the motion, which was adopted.

Reports of Executive Committee, Director, and Hon. Treasurer.

The executive committee report with regret the resignation of Sir William Church from the chairmanship of the committee, in which he has been succeeded by Dr. Sidney Martin, F.R.S.; Sir William Church becomes a vice-president of the Fund. They record that the “ Stroud Laboratory ” at Mill Hill is now nearing completion, and is expected to be in working order within the next month. During the year material from the laboratories of the Fund has been supplied to ten investigators working in this country, and also to workers in Amsterdam, Brussels, Strasburg, and Brazil. On the other hand, material for investigation has been received by the Director from other laboratories. A list of the papers published from the laboratory during the year is appended.

Dr. J. A. Murray, the Director, summarises the papers in the eighth scientific report referred to by the Chairman. He states that the investigations on the venereal sarcoma of dogs and on the infectious sarcoma of fowls have been interrupted by the removal of the country laboratory to new premises, and the delay which has occurred in erecting the new laboratory. In consequence, Dr. Begg's work under the Atholstan Grant on these tumours is not yet far enough advanced for publication. The experiments on the production of lymphomatous tumours in mice, carried out to test the conclusions of Dr. James Young, have proved entirely negative, even when carried out with cultures of the supposed causal organism, kindly supplied by Dr. Young himself.

Sir George Makins, the hon. treasurer, reports that subscriptions and donations have amounted during the past year to £1335, an increase of £383 over the previous year, and, in addition, a grant of £500 has been received from the Worshipful Company of Goldsmiths. Legacies amounted to £5403 10*s*. 6*d*., against £3675 15*s*. 6*d*. last year: hence the total receipts, apart from dividends from investments, amounted to £7239. The general research expenditure has increased during the past year, excluding the Mill Hill and Stroud Laboratory account, by £2326 9*s*. 5*d*. This is largely accounted for by additional material, instruments, and chemicals, the publication of the eighth scientific report, and by the salaries of two additional members of the scientific staff.

The President's Speech.

The Duke of Bedford, in moving a vote of thanks to the executive committee, commenced by testifying to the loss sustained by the death of Sir John Tweedy, who had taken the greatest interest in the Fund for many years past as a member of the general committee. He went on to welcome Sir George Newman, the chief officer of the Ministry of Health, who had joined that body, and to congratulate Sir George Makins on a good financial year, and a substantial increase in the amount of subscriptions and donations. He referred to the approaching completion of the Stroud Laboratory at Mill Hill, provided, free of cost to the Fund, by the executors of the estate of the late Mr. Augustus C. Stroud. He concluded by explaining the relations between the Fund and the British Empire Cancer Campaign. It is now satisfactory, he said, to hear that the provisions formerly thought necessary by this Fund have been adopted, so that under the new articles of association of the British Empire Cancer Campaign an advisory committee is appointed consisting of members of the Royal Society and of the Medical Research Council to advise on the allocation of funds for scientific research; and the Imperial Cancer Research Fund has appointed representatives on the Grand Council of the Campaign.

A cordial vote of thanks to the Duke of Bedford for presiding at the meeting having been proposed by Sir Humphry Rolleston, Bart., the proceedings terminated.

MEMORIAL TO THE LATE MR. G. P. NEWBOLT.—A fund has been opened to establish a memorial to the late Mr. Newbolt in the Royal Southern Hospital, Liverpool, where he had filled the post of senior surgeon for a quarter of a century. The organising committee has deemed it fitting that, in addition to a portrait of Mr. Newbolt, the memorial might take the form of carrying out certain improvements in the hospital that Mr. Newbolt had at heart. These are: (1) the extension of the X ray department; and (2) provision of additional accommodation for the nursing staff. Donations may be sent to Mr. Lyon H. Maxwell, hon. treasurer, at the hospital, or to any of the members of the Memorial Committee, whose names will be found in our advertisement columns.

[illegible]

[illegible] outbreak of this [illegible] Williamson in THE [illegible] was dealing with [illegible] described by Dr. David [illegible] Epidemic Pleurodynia in [illegible] of May of this year. The [illegible] occurred in a large infirmary in [illegible] 1238 boy inmates. 141 were [illegible] symptoms were, after a short period [illegible] in the chest or abdomen, headache, [illegible] total duration of the fever was from [illegible] convalescence was rapid, and there [illegible]. No reference is made to the presence [illegible] friction—perhaps the stethoscope was not used. Laboratory investigations were thoroughly carried out with negative results. [illegible] also gives references in medical literature [illegible] similar outbreaks in other parts of America, and [illegible] interesting to read the various descriptive titles [illegible]. Amongst these are "The Devil's grip," "Intercostal myositis," "Dengue," and "Epidemic transient diaphragmatic spasm." Dr. Williamson has supplied [illegible] another name, and his clinical findings seem to justify the term epidemic pleurisy. Perhaps the illness is not severe enough to attract the attention of public health authorities, but any further experiences of this condition from those in charge of schools or other institutions would be welcomed.

I am, Sir, yours faithfully,

July 21st, 1924. G. A. SUTHERLAND.

CAPT. KATER'S "PULSEOMETER"?

To the Editor of THE LANCET.

SIR,—Some remarkable antiquated instruments have been recently presented to the Museum of the Royal College of Surgeons of England by Miss Rundle, niece of their deceased owner, Mr. Henry Rundle, F.R.C.S., consulting surgeon to the Royal Portsmouth Hospital. Many were clearly out of date and must be considered as the stock of a predecessor. Among them is a Quain's stethometer of the second pattern, as modified on the suggestion of Coxeter. It is figured and described in the *Medical Times and Gazette* (1862, i., 595). Sir Richard Quain's original stethometer had been already figured and described in the same manner in THE LANCET, vol. i., 1851, p. 126.

Another dial-bearing instrument remains enigmatical. The following words are distinctly printed on the dial: "H. Kater Invr. Gilbert & Son, London." It is a cylindrical brass instrument, nearly 2 inches in height, with an enamelled dial, as in a watch, an inch and a half in diameter. This dial is marked to 100, subdivided into 10 parts, and a large indicating hand works from the centre. Its lower part is occupied by a lesser dial divided into 12 parts, and furnished with a smaller indicating hand. This dial is supported on a tripod, three brass rods fixed on a platform, a circular brass plate which screws on to the cylinder. There is a space of about 1 inch between the dial and a split pin on the centre of the platform. The larger indicating hand is governed by a small cog inside the dial, which was probably turned either by a piece of elastic or a spring, now absent, but it must have stretched between two fittings one of which is fixed in the pin of the cog-wheel of the large indicating hand, while the other was fitted into the split pin in the centre of the platform. The small cog of the larger hand rotates the big wheel on the small dial, which is gauged to 1 in 100. The brass cylinder is perforated by 24 circular holes a quarter of an inch in diameter—the object of this arrangement is not clear.

The nature of this instrument is mysterious. Mr. [illegible] Hopkins, a surgeon's cutler of nearly 60 years' experience, maintains that it is probably a pulse-counter, having known similar contrivances that were in use many years ago. This instrument bears the name of Capt. Kater, F.R.S. (1777–1835), a man of science whose life is recorded at some length in the "Dictionary of National Biography" and the "Encyclopædia Britannica." Numerous scientific memoirs are noted, but though Kater took a share in a work on cataract by Guthrie, there is no mention of any contrivance for use in medical research. I have consulted many of our elder physicians, and the librarians of the Royal Society of Medicine and of the Royal Colleges of Physicians and Surgeons, but after long research, for which I feel much indebted to these gentlemen, no mention of this "pulse-ometer" can be found, nor have any of them ever seen this contrivance.

Yet here is a sample preserved in the Museum of the Royal College of Surgeons. There must be others in existence, so perhaps some reader of THE LANCET can throw a little light on the subject. Mr. W. Finerty, assistant in the Museum, has carefully examined its mechanism, and the result is, as Sir Arthur Keith and myself admit, that there is no government over the control of the hands, and no mechanism for regulating time. Who can fill in the *hiatus valde deflendus?*

I am, Sir, yours faithfully,

ALBAN DORAN, F.R.C.S.,

Consulting Surgeon to the Samaritan Free Hospital.

The Museum, Royal College of Surgeons of England,
July 18th, 1924.

THE DILETTANTE RADIOLOGIST.

To the Editor of THE LANCET.

SIR,—Both at home and abroad radiologists are complaining of the havoc wrought by the dilettante in X ray treatment, and therefore your leading article of to-day's date is topical. The problem is delicate, the more so because radiology is still in its infancy, and the expert of to-day may, if he does not keep abreast of the times, be the dilettante of to-morrow. We cannot, in fact, draw a hard-and-fast line between the skilled and unskilled radiologist, and even the former must occasionally have unlucky experiences, either in person or among his patients. These considerations ought not, however, to divert us from a careful consideration of the means to be adopted in an attempt to bring X ray accidents down to the irreducible minimum. The procedure to which some radiologists would perhaps subscribe is the institution of an examination in radiology and the granting of a special diploma without which no one would be expected to give X ray treatment. You refer to the procedure without enthusiasm. The multiplication of special diplomas is regarded with disfavour by many for a variety of reasons, most of which leap to the eye. It might be argued forcibly that to discourage and almost forbid the practice of X ray treatment, save in the case of holders of some special diploma, would be to make too great an incursion into the liberty of doctors, and that the precedent thus created might have undesirable consequences It might, for example, lead to the suggestion that in other fields of therapeutics a similar tacit or implied veto should be imposed. The expert, or the physician who considered himself an expert, in the administration of tuberculin might plead for a special tuberculin licence, arguing that tuberculin may be a lethal weapon in the hands of the less expert. The same argument would be applicable to the administration of insulin, which requires greater care and knowledge than the prescription of castor-oil.

The analogies are not sound, and radiology is in a peculiar position. In some respects it is comparable with aviation. An ordinary diploma to practise medicine may be compared with a licence to drive a motor-car, and a special diploma in radiology with an aviator's certificate. A highly skilled mechanic may be perfectly qualified to drive others in a motor-car, but if he were not a fully qualified aviator we would not trust him to take us for a flight. With growing knowledge of the risks of X ray treatment, the public may require of the practitioner giving X ray treatment that he possess a special diploma or can show other evidence of expert knowledge in this field. And to protect himself in case of mishaps and consequent lawsuits, the practitioner who gives X ray treatment may find a special diploma of great value. These things must be borne in mind.

I am, Sir, yours faithfully,

July 19th, 1924. SPECIALIST IN OTHER FIELDS.

The Services.

ROYAL ARMY MEDICAL CORPS.

PROMOTION EXAMINATIONS.

THE King's Regulations have been amended so as to provide that, as from April 1st, 1925, a major of the Royal Army Medical Corps before promotion to lieutenant-colonel will be examined in the subjects laid down in Appendix X. of the Regulations. The examination in these subjects may be taken at any time after an officer's promotion to the substantive rank of major, provided that the candidate can produce a certificate from a D.D.M.S. or an A.D.M.S. to the effect that he has received instruction in the subjects covered by the examination, and that he is considered fit to present himself for examination. In order to assist officers in their preparation for this examination all necessary arrangements will be made for the adequate instruction of majors, Royal Army Medical Corps, in army medical organisation and administration, hygiene, and the employment of the medical services in peace and war. This instruction will be carried out by means of lectures followed by discussions, war games, and field exercises, by the attachment of officers to the different departments in hospitals and, where possible, to the offices of administrative medical officers, for instructional purposes.

TERRITORIAL ARMY.

N. W. Hammer, D. L. Kerr, and P. J. Stokes to be Lts.

Lt. W. B. A. Lewis (late King's Shropshire L.I.) to be Lt.

Sanitary Companies: Capt A. S. Hebblethwaite (late R.A.M.C., T.F.) to be Maj. and to comd. 6th (Northern) Sanitary Company.

Supernumerary for service with the O.T.C.: Capt. W. E. Le Gros Clark (late R.A.M.C., S.R.) to be Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lts. (D.) T. B. Cooper, W. M. Bull, G. K. MacLennon, and W. H. Hume (proby.) to the *Victory*, and to R.N. Hospital for training.

ROYAL AIR FORCE.

The undermentioned are transferred to the Reserve, Class D.2: Squadron Leader E. P. Punch, and Flight Lts. C. H. B. Thompson and B. C. W. Pasco.

INDIAN MEDICAL SERVICE.

Maj. (now Lt.-Col.) G. Browse relinquishes the actg. rank of Col. on ceasing to hold the appt. of A.D.M.S. (Nov., 1919).

Capt. J. H. Barrett relinquishes his temp. commn.

THE LATE DR. A. MANTLE.—Dr. Alfred Mantle, of Swan-road, Harrogate, who died suddenly on July 10th while on a visit to a professional colleague in the town, was in his seventieth year. He received his medical education in the London Hospital, graduating M.R.C.S. Eng. in 1873 and M.B. Durh. in 1880. Two years later he obtained the M.D. Durh., and in 1893 the M.R.C.P. Lond. He commenced practice in Halifax and became one of the senior physicians to the Halifax Royal Infirmary. He held for a time the office of president of the Halifax Medical Society and the Bradford Medico-Chirurgical Society. About 1903 he settled in Harrogate, and later became president of the Harrogate Division of the B.M.A. and of the Harrogate Medical Society, and a trustee of the Holt Homes at Harrogate for Halifax people. Dr. Mantle published articles in the medical press, dealing mainly with the ætiology and treatment of rheumatism, and a short time ago won an international prize of £120 for an essay on the subject of rheumatism, and earmarked the sum for the benefit of children suffering from rheumatism and consumption.

Parliamentary Intelligence.

HOUSE OF LORDS.

WEDNESDAY, JULY 16TH.

Smoke Abatement Bill.

Earl DE LA WARR moved the second reading of the Public Health (Smoke Abatement) Bill, which he said was designed to amend the law relating to smoke nuisances. The measure was on similar lines to those introduced on two previous occasions. The only hope of getting the Bill passed this session was by general agreement.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 16TH.

Modern Sewage and Water Systems in Britain.

Mr. WALTER BAKER asked the Minister of Health how many local authorities in this country had not installed modern sewage and water systems owing to their inability to raise the necessary financial assistance.—Mr. WHEATLEY replied: I regret that I have no information of the number of authorities who have not installed modern sewage and water systems because of lack of means.

Evidence before Lunacy Commission.

Mr. ROBERT RICHARDSON asked the Minister of Health whether his attention had been called to a circular letter issued by the Secretary to the Royal Commission on Lunacy, intimating to those desirous of giving evidence before it that in the event of their application being "turned down" they would not be notified of this decision, but would be left in uncertainty for an indefinite period; and would he take steps to see that some more satisfactory procedure was adopted and, further, that a reason for rejection of the evidence should be given, in order that the public might feel no lack of confidence in the selection of evidence made by the Commission.—Mr. GREENWOOD replied: The hon. Member has been misinformed as to the terms of the letter to which he refers. A very large number of persons have already applied to give evidence before the Royal Commission; and, in the meantime, such persons have been informed that their applications will receive consideration, and that if the Commission decide to hear evidence from them, a further communication will be sent. I should add that the procedure of a Royal Commission is entirely within its own discretion.

Hospitals and Sanatoria in Rural Districts.

Mr. ERNEST BROWN asked the Minister of Health whether any document was in the possession of his department showing the number of hospitals, isolation hospitals, tuberculosis sanatoria, asylums for the mentally defective, and Poor-law institutions situated in agricultural parishes; and if he would make it available to Members of the House for county constituencies.—Mr. GREENWOOD (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend is afraid that no document giving the information which the hon. Member has in mind is available. He will be glad, however, to endeavour to obtain information as regards any particular parish for which hon. Members may ask.

Dust and Refuse Heaps in London.

Mr. GILBERT asked the Minister of Health whether his department had recently considered the question of dust and refuse disposal in London and greater London; whether he was aware that there were now several refuse dumps in the lower reaches of the Thames which were burning through self-combustion, and were a great nuisance to the districts concerned; and whether, in view of the importance of the subject, he would consider as to a committee being set up to fully consider the matter, in view of the development of new housing schemes outside London.—Mr. GREENWOOD replied: A list of special precautions in connexion with refuse tips was prepared by my department in 1922, in consultation with local authorities; and my right hon. friend is advised that, where these precautions are observed, nuisances are avoided. He is having special investigations made as to the conditions in the lower reaches of the Thames.

Pension Scheme for Nurses.

Mr. ATHOLL ROBERTSON asked the Minister of Health whether he could see his way to establish a pension scheme for nurses on a contributory basis, with substantial aid from the State, for all nurses that had faithfully and continuously served public bodies, hospitals, and other institutions, and give assistance to the private nurse in a fair and reasonable way.—Mr. GREENWOOD replied : While my right hon. friend is in sympathy with the object which the hon. Member has in view, he is advised that the adoption of such a scheme as is suggested would be wholly impracticable.

Deaths from Vaccination.

Mr. BROAD asked the Minister of Health how many death certificates were sent in during the year 1923 in which the words vaccination or vaccine occurred ; what were the ages of the persons to whom these certificates referred ; and how these deaths were ultimately classified.—Mr. WHEATLEY replied : The words in question occurred upon 11 death certificates received during 1923 in England and Wales. In one of these cases (a child aged 1 month) it was ascertained upon inquiry that the vaccination had no connexion with the death, which was accordingly classified to the certified cause of heat-stroke. The remaining 10 cases, together with two others in which the words did not occur upon the certificate but which were ascertained upon inquiry to be due to vaccinia, have been classified as follows :—

Classified to vaccinia.	Classified to other causes in association with vaccinia.	
9 months	3 months	Cellulitis.
19 years	14 years	Septicæmia.
1 month	6 months	Convulsions.
6 years	1 month	Septicæmia.

Infant Mortality in Market Drayton.

Sir CHARLES OMAN asked the Minister of Health whether he was aware that Market Drayton had the highest rate of infant mortality of all the urban districts of Shropshire, including Shrewsbury, the figures being total urban districts 52 deaths per 1000 births, and Market Drayton 111 deaths per 1000 births, and that this excess of infant mortality had been consistently high since the formation of the urban district ; and whether he would cause some medical member of his staff to make inquiry whether the guardians of this urban district made sufficient provision for necessitous mothers, expectant mothers, and new-born children in the matter of medical aid, provision of milk, and other foods.—Mr. WHEATLEY replied : I am aware that the infant mortality rate in Market Drayton has generally been in excess of the average for the whole of the urban districts in Shropshire, but I would point out that this was not the case in two of the nine years which have elapsed since the formation of the urban district, and that the rate for 1923 was 85 per 1000 births, as compared with 111 in 1922. As regards the last part of the question, the county council is the authority responsible for maternity and child welfare work in this urban district, and I will arrange for an early inspection by one of the medical officers of the department, when inquiry will be made.

THURSDAY, JULY 17TH.

Tuberculosis Officers and Attributability.

Mr. ROBERT MORRISON asked the Minister of Pensions for what reason tuberculosis officers were prevented from expressing an opinion upon whether an ex-Service man's disease was attributable to, or aggravated by, war service ; when this instruction was issued by the Ministry ; and whether it was intended to continue it.—Mr. F. O. ROBERTS replied : The first part of the question does not quite correctly state the position. Tuberculosis officers of local health authorities are concerned with the treatment of tuberculosis and they are not invited to express an opinion as to entitlement in cases which come before them solely for medical treatment. But arrangements have been made for tuberculosis officers to sit as members of medical boards which deal with cases of this disease, and as such it becomes their duty to assist in arriving at the official decision on entitlement which can only reliably be formed when the records of the man's medical history during his service and subsequently are available. The arrangements in connexion with the part to be played by tuberculosis officers in cases of this type were made some 18 months ago. They have, I am glad to say, been found to work well.

Cost of Pensions Ministry Hospitals.

Mr. PHILIP OLIVER asked the Minister of Pensions what was the cost per patient per day of hospitals directly administered by the Ministry ; whether such cost was greater than the average capitation grant given to hospitals administered under the Ministry by voluntary societies ; and, if so, would he, as and when a reduction of bed accommodation became necessary, consider the advisability of closing wards in Ministry hospitals in preference to closing hospitals administered by such societies.—Mr. F. O. ROBERTS replied : The average daily cost to the Ministry per patient in hospitals administered by my department is approximately the same as the cost in hospitals administered for use by my department by voluntary bodies, namely, 8*s.* 8*d.* a day. The Ministry maintain separate institutions only where that course is necessary to supplement otherwise existing accommodation or to provide treatment for special war disabilities (for example, neurasthenia) for which adequate treatment is not otherwise obtainable. In pursuance of that policy the position is reviewed from time to time, and in the selection of accommodation to be relinquished the principal determining factors must be the type of treatment for which accommodation is required and the situation of the various institutions.

Maintenance of Pauper Lunatics.

Mr. CHARLES EDWARDS asked the Minister of Health whether he was aware that the amount of 4*s.* per head repaid to boards of guardians under the 1888 Act for the maintenance of pauper lunatics in asylums was totally inadequate ; and would he take steps to secure that at least half of the actual cost for the maintenance of such patient should be repaid to guardians from national funds.—Mr. GREENWOOD replied : Legislation would be required for the alteration of this grant, and my right hon. friend cannot undertake to introduce such legislation at the present time.

Mentally and Physically Defective Children.

Mr. ACKROYD asked the President of the Board of Education the number of mentally defective and the number of physically defective children for whom grants were being paid to local education authorities, and how these numbers compared with 1914.—Mr. TREVELYAN replied : During the year ended March 31st, 1923, grants were paid to local education authorities in respect of an average attendance of 12,907 mentally defective children and 9793 physically defective children. The Board also paid grants in respect of that year to bodies other than local education authorities for an average attendance of 297 mentally defective children and 1732 physically defective children. Thus they paid grants for a total average attendance of 13,204 mentally defective children and of 11,525 physically defective children. For the year ended March 31st, 1914, the total average attendance of mentally defective children on whom the Board paid grants was 11,307, and on physically defective children 6075.

Danger to Health of Imported Hides, &c.

Mr. TILLETT asked the Home Secretary whether he was aware of the hardships and risks to health and life imposed upon workers handling hides, horns, hoofs, bones, wool, and hair, particularly those imported from India and Asia generally ; and, in view of the fact that docks, wharves, quays, warehouses, and workshops at which these commodities were handled for transporting and sorting were not scheduled under the Factory Acts, would he take steps to include in the forthcoming legislation such clauses as would cover all those engaged in the handling of these commodities.—Mr. HENDERSON replied : I am well aware of the risk from anthrax to which these workers are exposed, and will take every possible step to meet it. There is already power under the Factory Acts to make regulations for the protection of persons employed in docks and the other premises mentioned, and regulations are in force in regard to the handling of hides imported from Asia or Africa. Experience shows, however, that the most, if not the only, effective remedy consists in the disinfection of the material, and the most hopeful line of advance, therefore, will be to utilise, wherever practicable, the powers conferred by the Anthrax Prevention Act, 1919, by providing for compulsory disinfection at the port of entry. As my hon. friend knows, certain materials are already being compulsorily disinfected at the Government station at Liverpool, and the extension of this requirement to other materials, and in particular to East India wool, is now under consideration.

Silicosis among Miners.

Mr. FREDERICK GOULD asked the Home Secretary if he could now give further information as to the reported cases of silicosis among miners ; and whether any progress had been made with a view to schedule the same as an industrial disease under the Workmen's Compensation Act.—Mr. HENDERSON replied : As the hon. Member will be aware, the reported occurrence of silicosis among coal-miners, due to their work in the mines, has been the subject of inquiry by the Health Advisory Committee of the Mines Department, but I am informed by the Mines Department that the evidence so far received has proved to be untrustworthy. The investigation is, however, being continued.

FRIDAY, JULY 18TH.

Wireless at St. Bartholomew's Hospital.

Mr. WALTER BAKER asked the Minister of Health how many institutions under his control had been equipped with wireless receiving sets: and whether, having regard to the success of the installation at St. Bartholomew's Hospital, he would look favourably on any proposal to install such apparatus.—Mr. WHEATLEY replied: I have no information as to the number of institutions in which wireless sets have been installed. I am advised that if such an installation is desirable for the well-being of the inmates of the institution it would be competent to the authority to incur reasonable expenditure for the purpose.

MONDAY, JULY 21ST.

Vaccination in India.

Mr. CLARKE asked the Under Secretary of State for India if his attention had been called to the imprisonment of parents in Hyderabad, Sindh, who had conscientious objections to vaccination: and, if so, if it was the intention of the Government of India to amend the Vaccination Act so as to assimilate the law to that prevailing in this country.—Mr. RICHARDS replied: The answer to the first part of the question is in the negative. I am not aware that the Government of India contemplate an amendment of the Vaccination Act.

Anthrax Contagion in Indian Wool.

Mr. TILLETT asked the Under Secretary of State for India the conditions of labour enforced in India upon workers handling, sorting, and transporting hides, horns, hoofs, bones, wool, and hair, and what regulations were imposed to prevent the contagion of anthrax from reaching such commodities; and could he indicate the hours of employment and system of labour operating amongst those engaged in handling these commodities.—Mr. RICHARDS replied: Workers in India employed in factories, including wool mills, are subject to the provisions of the Factories Act, a copy of which I shall be happy to supply to my hon. friend. A provision was added to the Act in 1922 enabling the Governor-General in Council to make rules for the disinfection of wool used in factories which may be infected with anthrax spores. So far as I am aware no rules have been framed, probably because anthrax is an exceedingly rare industrial disease in India.

Indian Medical Department Allowances.

Mr. HOPE SIMPSON asked the Under Secretary of State for India whether, seeing that during the war officials of the Indian Medical Department drew separation and other kindred allowances and that under Royal Warrant, A.O. 357 dated August 28th, 1920, marriage allowance was substituted for those allowances, whether members of the Indian Medical Department now drew marriage allowance; and, if not, for what reason that allowance was withheld from them.—Mr. RICHARDS replied: Marriage allowance was granted in India to personnel of the British Service and to certain other ranks drawn from the British Service and serving under the same general conditions of pay. It was not considered necessary to extend the allowance to the Indian Medical Department, the personnel of which, with few exceptions, are domiciled in India. They were allowed to draw separation allowance on account of special war-time conditions.

Death and Sickness in Gold Coast Mines.

Dr. CHAPPLE asked the Secretary of State for the Colonies whether he had yet been able to discuss with the Governor of the Gold Coast Colony the death- and sickness-rate in the mines of that colony: and, if so, whether he was in a position to make any statement.—Mr. THOMAS replied: I have decided to forbid further recruiting for the mines in the Northern Territories of the Gold Coast until conditions are improved. As a first step I arranged a few days ago that Sir William Simpson, a sanitary expert of high authority, should proceed to the colony to investigate and furnish me with a report on the sanitary conditions of the mines and mining villages, and the reasons for the high death-rate among the labourers, and to suggest measures for their improvement. Sir William Simpson is already on his way to the Gold Coast.

Visits to Lunatics in Asylums.

Sir JOHN MARRIOTT asked the Minister of Health whether the parents of a patient detained in a lunatic asylum were, by regulation, denied access to, or communication with, the patient if the wife of the patient raised objection to such communication.—Mr. WHEATLEY replied: I am not aware of any such regulation. The question of allowing the friends or relatives of a patient to visit or of withholding communications addressed to a patient is entirely within the discretion of the medical superintendent of the mental hospital, who would be guided in his decision by the patient's condition.

Medical News.

UNIVERSITY OF OXFORD.—The following awards of Theodore Williams scholarships are announced:—Human Anatomy (£50 for two years): Denis Hubert Brinton, New College. Physiology (£50 for two years): George Eric Macdonald, New College. Pathology (£60 for two years): Thomas Cecil Hunt, B.A., Magdalen College.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were successful:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part I., Physics and Electrotechnics.—John Lavelle, Walter M. Levitt, Frewen Moor, Cusach J. K. O'Malley, James R. K. Paterson, John V. Sparks, and Maurice Weinbren.

Part II., Radiology and Electrology.—Arthur R. Colyer, Charles R. Enticknap, Alexander C. Fowler, Shanazar G. Galstaun, Pratap S. Khosla, John Lavelle, Walter M. Levitt, Alexander G. MacLeod, Thomas D. Overend, James R. K. Paterson, Gordon D. Thomson, Kenneth F. Vickery, John Wall, and Barbara G. Wood.

UNIVERSITY OF MANCHESTER.—As a result of the recent examination, the following obtained certificates in school hygiene, subject to confirmation by the Senate: Enid F. Stowell, M.B., Ch.B., D.P.H., and Ethel White, M.B., Ch.B., D.P.H.

The Sidney Renshaw Prize in Physiology has been awarded to W. H. Newton, and the University Prize in Medicine to Robert Newton. Gold medals were awarded on dissertations for degree of M.D. to K. V. Bailey and F. R. Ferguson. The Sheridan Delépine Fellowship in Preventive Medicine was awarded to L. P. Lockhart.

UNIVERSITY OF LIVERPOOL.—As the result of the recent examinations in the Faculty of Medicine, the following are the names of the successful candidates:—

DEGREE OF M.D.

H. Cohen, M. J. Cohen, and B. L. McFarland.

DEGREE OF PH.D.

T. Southwell.

DEGREES OF M.B. AND CH.B. (HONOURS).

Class II.—*C. B. Bamford, †Helen S. H. Brown, †A. Pool, *E. Scott, and †Gwennie Williams.

* Distinction in Medicine. † Distinction in Obstetrics.

FINAL EXAMINATION FOR DEGREES OF M.B. AND CH.B.

Part III.—Mary G. B. Allen, R. V. Berrington, C. H. Bradley, J. S. Bradshaw, R. S. Brock, Alison M. Brummitt, A. Cooke, J. W. Cowen, J. D. Craig, M. M. Datnow, Edwina M. Davies, L. Davies, R. Y. Dawbarn, Eileen M. Deane, W. T. Donovan, H. Duff, J. B. Elleray, H. W. Fell, H. R. Fisher, F. F. Fuller, G. A. Garrett, Susan Gluck, T. A. Griffiths, D. C. G. Hanlon, T. Hare, Fannie S. Holt, G. P. Huws, L. E. Johnson, R. W. Jones, R. Jones, A. L. Kerr, D. Kippax, J. Leggate, W. E. Lishman, J. H. M. Little, G. Lowe, G. Macdonald, Margaret S. Macdonald, Phyllis Marsh, G. A. Moulden, A. Newton, R. J. Prydderch, Gwendolin H. ff. Roberts, E. Rowlands, J. A. Scott, G. V. L. Taylor, Marjorie A. Unsworth, Mabel J. Watterson, N. Weinberg, and H. S. Welton.

Part II.—R. M. Ainsworth, H. W. Altschul, A. T. Ashcroft, Ethel Barrow, E. I. Bieber, ‡C. A. Birch, H. M. Boston, B. H. Brickman, W. G. Brookes, N. L. Corkill, R. F. Corlett, D. E. Davies, P. V. Dillon, J. L. Donnelly, ‡L. Earlam, J. C. Edwards, Sybil O. Edwards, ‡C. J. S. Garton, M. Goldberg, Dorothy A. Gough, Frances M. Greenhalgh, R. I. Greenshields, Gwyneth Griffith, C. A. Harris, ‡J. Hatton, Beryl M. Hawthorn, J. C. Heal, R. E. Horsfall, E. Hughes, ‡F. Hughes, S. M. Katz, C. Kaufman, B. Kay, J. E. S. Lloyd, W. J. Lloyd, ‡L. J. A. Loewenthal, T. R. E. Longton, H. McGrath, ‡G. McNichol, K. N. Mawson, J. W. Melville, F. Murgatroyd, E. L. Murphy, Winifred A. Nicholson, H. E. Pearson, H. Peaston, J. W. Reid, §Miriam Roskin, J. C. Ross, Ruth Simpson, N. P. Slade, I. Thomas, Margaret E. Thomas, E. F. Thompson, C. E. Unsworth, J. Unsworth, Rosalind Vacher, J. E. Walker, and F. W. Yates.

Part I.—R. M. Ainsworth, M. A. E. Azzam, H. E. Barrow, C. Baxter, B. H. Brickman, A. S. S. Brown, D. Cohen, J. Katz, Alice M. Luck, J. W. Melville, E. L. Murphy, Irene M. Neal, J. J. O'Donovan, Mary T. Penrice, W. J. Pierce, Mary A. Silcock, and W. L. Webb.

‡ Distinction in Forensic Medicine and Toxicology.

§ Distinction in Public Health.

DIPLOMA IN PUBLIC HEALTH.

W. J. Birchall, R. W. Brookfield, B. L. Chopra, H. M. Cohen, F. S. Fowweather, E. S. Gawne, Annie R. Niven, C. J. de V. Shortt, and J. F. D. Shrewsbury.

UNIVERSITY OF LEEDS.—At a congregation of the University held on July 5th degrees were conferred by the Chancellor, the Duke of Devonshire. Among these were the following Degrees in Medicine:—

Ch.M.—Digby Chamberlain.

M.B., Ch.B. (Second-class Honours).—Thomas H. B. Bedford, Andrew M. Claye, Harry Edelstein, Harry Ross, and Joseph G. Ward.

Ordinary.—William C. Abell, Herbert Bruce, Alexander Cannon, Joseph Cardis, Aileen N. Claye, Frederick Clegg, Maria L. Gaunt, George D. Gordon, Muriel D. Graham, Miles Hutchinson, John W. Pickard, Kathleen M. Potter, Leslie N. Pyrah, Norman A. Rymer, Norris A. Scadding, Geoffrey H. Sellers, John E. A. Simpson, George R. Sunley, Donald M. Sutherland, Harry Taylor, Wilfred Thistlethwaite, Edward W. Vincent, Hester E. Woodcock, and Donald Yates.

Memorial Service to the late Sir Sydney Russell-Wells.—A service in memory of the late Sir Sydney Russell-Wells was held on July 22nd in St. Margaret's Church, Westminster, where members of his family and a large number of his private friends were present, as well as many representatives of public bodies with which he was connected.

Addenbrooke's Hospital, Cambridge.—A post-graduate course will be held from Sept. 30th to Oct. 3rd inclusive. The course will consist chiefly of demonstrations of medical and surgical cases and of pathological specimens; also of advances in clinical pathology and biochemistry likely to be of interest to general practitioners. There will be no fee. A syllabus will be supplied later on application to the hon. secretary, Dr. Aldren Wright, at the hospital.

Tropical Disease Prevention Association.—Dr. Louis W. Sambon has left for Iceland under the auspices of this Association to continue there the epidemiological researches as to the causation of cancer which he began last year in Italy. It is proposed to extend his mission later to the West Indies, where he would carry on investigations on the same lines and establish comparisons between the factors of environment, climate, and natural history as bearing upon the incidence and causation of this disease.

Association of Certificated Blind Masseurs.—The sixth annual general meeting of this Association was held on July 17th in the Armitage Hall of the National Institute for the Blind (by kind permission of the authorities). The meeting was presided over by Sir Robert Jones, and the chair was taken by Mr. Michael Whitfield, B.A., who is himself a blind masseur. Sir Robert Jones spoke of the excellent work done by members of the Association, and expressed the desire that the Association would extend its sphere of usefulness over an even greater area.

Medical Congress and Exhibition at Seville—The acting British Consul at Seville has forwarded to the Department of Overseas Trade a copy of the programme of the Second National Congress of Medicine to be held at Seville from Oct. 15th to Nov. 5th next, and a copy of the regulations for the Medical and Hygienic Exhibition to be held during the Congress. The Exhibition is open to exhibitors of all nationalities, but the Congress is limited to medical men authorised to practise in Spain, Portugal, and South America. The programme of the Congress (in Spanish) and a translation of the regulations for the Exhibition may be consulted at the Department of Overseas Trade (Room 53), 35, Old Queen-street, Westminster, London, S.W. 1.

Medical Hydrology at Cheltenham.—At Cheltenham on July 12th and 13th, hospitality was provided by the local medical men to medical guests. Visits of inspection were paid to the Pump Room and Medical Baths, the Pittville Spa establishment and the hospital, and motor drives were taken to Cleeve Hill and other resorts. Dr. Fortescue Fox, on behalf of the Committee for the Study of Hydrology in Great Britain, delivered an address and described the policy of the Committee as two-fold: (1) to establish permanent recognised instruction in medical hydrology in the medical schools of this country; and (2) to obtain for the British spas the recognition and assistance to which they were entitled from the Government. Great progress, he said, had been made in the first of these aims, and lectures were now being given in medical schools in London and in several provincial universities; while visits of medical men and medical students to the various spas were being organised. In addressing the student visitors, Dr. Fox explained the particular properties of Cheltenham as a spa. The action of the Cheltenham climate and baths upon invalids was sedative or calming, and not, as at most of the British spas, tonic or exciting. The waters of Cheltenham were first of all eliminative, and there was a great variety of toxic or poisonous conditions to which they were applicable, but it must never be forgotten that external treatment was an essential part of hydrological work. Short lectures and practical demonstrations were then given by Dr. A. G. F. Forster on radiant heat, Dr. S. M. Hebblethwaite on the Vichy douche, and Dr. J. R. Collins on the paraffin, contrast, and whirlpool baths. Dr. R. Kirkland read a paper on the use of the waters, and cases from the hospital were shown by Dr. H. F. Powell.

The board of management of the London School of Hygiene and Tropical Medicine have appointed Mr. R. W. Harris, formerly an assistant secretary at the Ministry of Health, to be the secretary of the school.

General Medical Council and the Irish Free State.—On July 16th the Government of the Irish Free State introduced a Bill on Dail Eareann to authorise the General Medical Council to continue to exercise jurisdiction and authority under the Medical Acts in respect of medical practitioners in the State for the period of one year.

The first number of the *Cripples Journal*, a shilling quarterly concerned with the progress of medical and social work in the care and cure of cripple children here and abroad, will be published to-day, July 26th, by the Shropshire Orthopædic Hospital, Oswestry. Among its contributors are Sir Robert Jones, Sister A. G. Hunt, and Dr. McCrae Aitken.

North Persian Forces Memorial Medal.—Wing Commander Harold E. Whittingham, Royal Air Force Medical Service, has been awarded the North Persian Forces Memorial Medal for the year 1923 for a paper on Observations on the Life-history and Bionomics of *Phlebotomus papatasii*, written in conjunction with Flight Lieut. A. F. Rook, R.A.F. Medical Service. This is the first award of the medal, which, in accordance with the terms of the Trust Deed of the Memorial Fund, is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding 12 months by any medical officer of under 12 years' service of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or of the Colonial Medical Service, provided the Memorial Committee consider the papers published have attained a standard of merit justifying an award.

Royal Medical Benevolent Fund.—At the last meeting of the committee 30 cases were considered and £508 10*s*. voted to 29 applicants. The following is a summary of some of the cases relieved:—

Widow, aged 64, of L.F.P.S. Glasg., 1896, who practised in Waterloo-road, London, and died September, 1902. On the death of her husband applicant was left unprovided for with the exception of a little help from her daughter. The daughter married and her husband died, and left her with a child now aged 7. The daughter took a post as waitress in a city café—unfortunately, she died in March of this year. The mother is now left without means and this little girl. Customers at the café collected £40, and a customer who has taken an interest in the case is allowing £1 a week at present. Voted £26.

Daughter, aged 64, of M.R.C.S. Eng., 1869, who practised in London and S. Africa and died in 1869. The family managed to live comfortably until the war. Most of their funds were invested in Russia and have all been lost. Since then the applicant, whose health is not good, has earned an average of about £14 a year by needlework. She receives from investments £25, and from a private charity £25, and a friend who can scarcely afford it £20. She lives at a ladies' home at Hampstead, and pays £56 a year. Would greatly appreciate a little help as she finds it difficult to pay her way. Voted £18 in 12 instalments.

Widow, aged 47, of L.S.A. Lond. who practised at Bristol and died in April, 1924. There are two children—daughter, aged 18, at school, and boy, aged 16, at school, who was at Clifton College. The applicant is arranging to sell the house she now resides in and to take a smaller one. Expects when all her affairs are settled to have about £500 left. Proposes to take one or two paying guests. Present rent £75 a year. Voted £10.

Widow, aged 48, of M.B. Aberd., 1895, who practised in Scotland and served in R.A.M.C. (T.) and in the Royal Air Force. Suffered from cancer and died in London Hospital, May 7th, 1924. During his illness help was given by the Officers Association and other funds. These have now stopped. Widow and family living in a furnished house at £8 8*s*. per month. Eight children, ages 10 years to 25. The eldest son is a medical student. It is likely to be three months before the question of pension is settled, and in the meantime the widow is without means and asks for some immediate help to provide home expenses. Voted £20.

Widow, aged 39, of L.R.C.P. & S. Edin. who practised at Liverpool and died September, 1923. *Prior to his death husband* went to S. Africa and took his typist with him, and left her all his belongings. The applicant was left with a daughter now aged 15, who is being educated at a convent in France in return for giving music and English lessons. Applicant has endeavoured to make a living as a musical comedy actress and earned £30 during the early part of the year, but has contracted severe eczema in the ankles which has stopped this. Mrs. Fuller has interviewed her and prepared a report. Lives with a sister and contributes towards the rent. Voted £20 in two instalments.

Widow, aged 30, of L.R.C.P. & S. Edin., 1888, who practised at Stockton-on-Tees and died June 24th, 1924. Her husband, who was a Territorial, joined up for the war and served mainly in the East. He contracted severe heart disease and died after a long illness. Applicant's savings were practically exhausted in looking after her husband, and she is now practically without funds. Has a boy aged 6 Applicant could take a post if arrangements could be made for the boy to be looked after. The Fund gave £26 to the husband just before he died. Voted £20.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 12TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 57; scarlet fever, 1413; diphtheria, 654 (as against 619 of the previous week); enteric fever, 126; pneumonia, 497 (as against 657 of the previous week); puerperal fever, 32; cerebro-spinal fever, 6; acute poliomyelitis, 22 (as against 12 of the previous week); acute polio-encephalitis, 4; encephalitis lethargica, 81 (as against 103 of the previous week); continued fever, 1; dysentery, 5; ophthalmia neonatorum, 121. There were no cases of cholera, plague, or typhus fever notified during the week. Of the 57 cases of small-pox, 25 were notified from the county of Derby (Derby 6, Chesterfield 14, Chesterfield R.D. 5); 9 from the county of Nottingham (Nottingham 6); 2 from the county of Warwick (Coventry); 11 from Yorks, N. Riding (Middlesbrough 10); 7 from Yorks, W. Riding (Rotherham). Of the cases of encephalitis lethargica, 12 were notified from the County of London (Battersea 1, Camberwell 2, Chelsea 1, Finsbury 1, Hackney 2, Holborn 1, St. Pancras 1, Southwark 1, Woolwich 2); 2 from the county of Buckingham (Wycombe); 7 from the county of Durham (Chester-le-Street 2); 8 from the county of Lancaster (Liverpool 2, Manchester 2); 4 from the county of Warwick (Birmingham); 10 from Yorks, W. Riding (Sheffield 5, Gt. Ouseburn 2).

Deaths.—The deaths from diphtheria in the aggregate of the great towns were 24 as compared with 17 of the previous week, and in London 0 as compared to 4 of the previous week.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 28th.—11 A.M., Surgical Registrar: Surgical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Addison: Surgical Wards.

TUESDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 12 noon, Dr. Burrell: Chest Cases. 11 A.M., Dr. Endean: Venereal Diseases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Pernet: Skin Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Medical Registrar: Clinical Methods. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY, August 1st.—11 A.M., Dr. McDougal: Electrical Dept. 11 A.M., Mr. Simson: Gynæcological Demonstration. 4 P.M., Dr. Archer: Chemical Pathology.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Dept. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on the Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

Appointments.

GOODWIN, A., M.D. Lond., F.R.C.S. Eng. and Edin., has been appointed Gynæcologist to the Prince of Wales's General Hospital, Tottenham.

WILKIE, D. P. D., M.Ch., M.D. Edin., F.R.C.S. Edin., to the Chair of Surgery in the University of Edinburgh.

General Infirmary, Leeds: MOIR, P. J., M.B., Ch.B. Glasg., F.R.C.S. Eng., Honorary Assistant Surgeon; LEE, HARRY, M.B., B.C. Camb., F.R.C.S. Eng., reappointed Honorary Ophthalmic Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: NOBLE, C. L., M.B., Ch.B. Edin. (Portsoy, Banff); HOWIESON, H. W., M.B., Ch.B. Glasg. (Bo'ness).

Vacancies.

For further information refer to the advertisement columns.

Acton Hospital.—R.M.O. £150.

Bedford County Hospital.—Asst. H.S. £130.

Birmingham City Municipal Bacteriological Laboratory.—Asst. Bacteriologist and Asst. Venereal Diseases Officer. £600.

Birmingham Cripples' Union Orthopædic Hospital.—H.S. £250.

Birmingham, Rubery Hill and Hollymoor Mental Hospital, Northfield.—Asst. M.O. £350.

Brighton County Borough Sanatorium.—Res. M.O. £350.

Cambridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæsth. £150. Also H.S. £150.

Cardiff City.—Res. Med. Supt. and Asst. M.O.H. £700.

Chesterfield and North Derbyshire Royal Hospital.—Cas. and Orthopædic H.S. £150.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. £125. Also Radiologist.

Croydon General Hospital.—Jun. H.S. £150.

Derby County Mental Hospital, Mickleover.—Sen. Asst. M.O. £450.

Freemasons Hospital and Nursing Home.—Res. M.O. £250.

Glasgow University.—Chair of Surgery.

Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—H.S. £175.

Jersey General Hospital and Poor-law Infirmary.—R.M.O. £200.

Leeds Public Dispensary.—Sen. Res. M.O. £200.

Lincoln County Hospital.—Jun. H.S. £200.

Liverpool University.—Derby Chair of Anatomy. £800.

London Temperance Hospital.—Cas. O. £150.

Miller General Hospital, Greenwich-road, S.E.—Sen. R.M.O. £250.

Newcastle-upon-Tyne Hospital for Sick Children.—Hon. Asst. S.

Pontypridd Union, Llwynypia Hospital.—Supt. M.O. £700.

Rochdale Infirmary.—M.O. 300 guineas.

Royal Devon and Exeter Hospital.—Asst. P.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. £100.

Sheffield Royal Infirmary.—Med. Reg. £400. Ophth. H.S. £60.

Sherwood Forest, Notts, Ransom Sanatorium.—Asst. R.M.O. £375.

Southampton County Borough.—Asst. M.O.H. £600.

Births, Marriages, and Deaths.

BIRTHS.

BOOBBYER.—On July 19th, at Warwick-road, Ealing, the wife of Dr. P. W. Boobbyer, of a son.

BUXTON.—On July 16th, at Wimpole-street, W., the wife of St. J. D. Buxton, F.R.C.S., of a son.

CANE.—On July 14th, at St. Luke's, Jersey, the wife of Major A. S. Cane, D.S.O., O.B.E., R.A.M.C., of a daughter.

GRIFFITH.—On July 16th, at Roydon, Asheldon-road, Torquay, the wife of Harold Kinder Griffith, F.R.C.S., of a daughter.

WORDLEY.—On July 17th, at St. Mildred's, Plymouth, the wife of Dr. Eric Wordley, of a son.

MARRIAGES.

BAIN—THIRKELL.—On July 19th, at St. Lawrence's Church, Catford, Lawrence Weir Bain, M.D., M.C., to Doris Marion, eldest daughter of Mr. and Mrs. Howard Thirkell, of Catford.

SATOW—NEILSON.—On July 16th, in the Cathedral, Westminster, Lawrence Lancaster Satow, M.C., M.R.C.S., &c., to Margaret de Verchères, younger daughter of Mr. and Mrs. Norman R. Neilson, of Neilsonville, in the province of Quebec, Canada.

DEATHS.

BALLARD.—On July 12th, at Walford House, Smarden, Kent, Richard Pitt Ballard, M.C., M.B., B.S., aged 38 years.

BUTLER.—On July 18th, suddenly, at his residence, Dinton House, Harrow Weald, George Henry Butler, L.R.C.S., L.R.C.P., in his 71st year.

MANTLE.—On July 10th, 1924 (very suddenly), Alfred Mantle, M.D., M.R.C.P., of Archway House, Harrogate.

PIDCOCK.—On July 16th, at a nursing home, George Douglas Pidcock, M.A., M.D., M.R.C.P., &c., of Hampstead, in his 73rd year.

WENYON.—On July 18th, at Lugano, Charles Wenyon, M.D., M.Ch., L.R.C.P., of Fitzjohn-avenue, Barnet, aged 75 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NORTH WALES UNIVERSITY COLLEGE, BANGOR.—On July 17th the honorary degree of LL.D. was conferred by the College on Sir Donald MacAlister "in recognition of his dintinguished services to medical science and as a university administrator."

DONATIONS AND BEQUESTS.—Lord Bearsted has informed Sir Arthur Stanley, treasurer of St. Thomas's Hospital, that he will contribute a sum of £5000 for the funds of the hospital provided that four other persons each contribute a similar amount.—The late Mr. Thomas Edward Dingwall, of Clapton Common, Middlesex, bequeathed to the Royal Northern Hospital, Holloway, £1000 for the purpose of founding a bed to be known as the "Thomas E. Dingwall Bed," "as a token of gratitude for the treatment he received at the hospital in the year 1894."—The Manchester business house of William Sutcliffe, Ltd., manufacturers and warehousemen, have commemorated the golden jubilee of the firm by sending a cheque for 50,000 shillings to the Lord Mayor as a gift to certain Manchester and Salford charities. They have expressed the hope that all firms who pass similar milestones will thus remember the local charities.—The late Miss Elizabeth Sophia Trotter, of Harrogate, besides large bequests to church and other institutions, left £1000 to the Hostel of St. Luke (Nursing Home), London; £2000 to the Royal Bath Hospital, Cornwall-road, Harrogate; £3000 to the Harrogate Infirmary; £500 to the Red Cross Society; £1000 to the Leeds General Infirmary; and £2000 to the Yorkshire Home for Incurables, Harrogate.

Notes, Comments, and Abstracts.

WHY ARE FACTORIES CLOSED TO THE MEDICAL OFFICER OF HEALTH?*

By Lieut.-Colonel F. E. Fremantle, O.B.E., M.P., F.R.C.S., F.R.C.P.

It is strange that so little attention has been paid to industrial hygiene by writers on the public health. The Registrar-General showed half a century ago that, as compared with the mortality of all males, taken as 1000, that of agricultural labourers[1] was only 602, of shopkeepers 973, of doctors 966; while the mortality for painters, plumbers, and glaziers was 1120, and that of men in iron and steel manufacture was 1301, of potters 1706, and that of unoccupied males 2215. Here, surely, was a key to the cause of much preventable sickness, inefficiency, and mortality. And yet the subject received little notice in the text-books or in the lectures and examinations for the Diploma in Public Health, until the Factory and Workshop Act, 1901, threw sanitary responsibilities for the workshops on the sanitary authorities. And then only in respect of certain limited functions. Sir John Simon's classic on English Sanitary Institutions makes no allusion to the supervision of health in factories; nor do Mr. and Mrs. Sidney Webb, in their handy book on "The State and the Doctor"; and I have searched my library in vain for any description of the Chief Inspectors' department and methods.

The reason is clear. Public health and its diplomas have been built up by the Privy Council, and the late Local Government Board, and by local authorities and their medical officers, pioneered by the army and the army surgeons in the Crimea under the acid test of war. They have been directed to the needs of the medical officer of health in this country; they have been limited by the experience and training of the only teachers available, with few exceptions medical officers of health, or inspectors under the Local Government Board. It is almost by chance, and only after great delay, that the "principles and practice of hygiene" are being extended to their proper scope, including the physiological and psychological conditions of the individual, the need of early correction of defects, the need of pure, rather than ad hoc research, the supervision of health in every walk of life from the cradle to the grave, under whatever Government department; and not least, the adaptation of individual and communal life to other climates and other racial, social, industrial, and parasitic surroundings. The forthcoming establishment of the London School of Hygiene and Tropical Medicine, due to the generous benefaction of the Rockefeller Trustees, and the wise coöperation of our Government, will be based on these broader lines.

[Colonel Fremantle then outlined the history of industrial hygiene, which, he said, was mainly confined to that of factory supervision by the Home Office. He traced this history from the Factory Reform Bill of 1802, the Factory Act of 1833, and the first appointment of certifying surgeons in 1844, up to modern times, when the dual control of the local authorities who employ medical officers of health and the Home Office, under which department the inspectors of factories and certifying factory surgeons work, leads to lack of coördination in many respects. He continued:—]

The Disadvantages of Dual Control.

One of the foremost and wisest of medical officers of health gives me privately his experience of the dual position in one of the big industrial cities: "I have felt strongly on this subject for a great many years. My own feeling is that the Home Office has not made their factory and workshop inspection a health service. They have a lot of very competent engineers and chemists, but they ought to have far more competent medical investigators and, I think, a medical chief. As you know, there is a duplicate control partly by the Home Office and partly by the local authority, and as a result, I am very sorry for the manufacturer, who frequently has an inspector from the Home Office and one from the local authority in the works on the same day and at the same time. The local authority's control of factories is almost a negligible one, dealing as it does with sanitary accommodation. In regard to workshops, our control, of course, is very much larger, but in recent years the Home Office has appointed so many workshop inspectors who go over all the work supposed to be done by the local authority, that it is a real hardship on the occupier of the workshop at times. great many lay inspectors recognise that they have to fi something to talk about, and suggest at every visit, so th the workshop owner never knows when he has done. Perso ally, I am not greatly concerned as to who should do the things, so long as they are done. If the local authority is take it in hand, then it ought to be a real workshop or facto service, and they must be given the control and responsibili necessary and must not be interfered with. At the prese time I believe that local authorities do very little, becau they are always up against something that the facto inspector has done or suggested. It is quite true that medical officer of health, I am supposed to have power investigate anything in the district. If I tried to find o what it was that was damaging the health of a set of worke in a particular factory I might be told to mind my own bu ness, and that it was the function of the factory inspect Consequently, the work is left unless, of course, it is a ve serious matter, and then one would report it direct to t factory inspector for investigation. I have said all this, b I do not want you to think that there is any friction betwe the Home Office inspectors and myself. They have alwa been most courteous and willing to help, and we could n have a nicer lot of men than those who are here just now.'

The Factories Bill.

[Colonel Fremantle criticised the findings of the depar mental committee on medical examination of young perso for factory employment, appointed this year by the Hon Secretary, in so far as its proposals (Cmd. 2135) we framed on the basis of the present administration. continued:]

The Factories Bill was subsequently introduced on Ma 22nd. It is a great consolidating and amending measu of 143 clauses and 100 pages, prepared under the la Unionist Government. The mere titles of the parts of t Bill indicate that the factory code and its administratio are essentially devoted to the health and physical welfa of the people: I. Health; II. Safety; III. Welfare—viz drinking-water, washing facilities, first-aid, facilities f sitting, keeping and drying clothes, protective clothin welfare orders, weekly rest-day; IV. Health, Safety an Welfare (Special Provisions); V. Accidents and Industri Diseases; VI. Employment of Women, Young Persons, an Children; VII. Special Applications and Extensions VIII. Home-work; IX. Piece-work and Wages; X.-XI Administrative, Legal and Definitive.

There could be no doubt to a judicial referee that thes matters are essentially part—and a very large and essenti part—of the science of public health. And the furthe limitations and standards to be imposed are, from th standpoint of those concerned for the national health, a to the good. The Factory Department, indeed, of the Hom Office, is a second Ministry of Health; or rather, since th Board of Education is a second, this is a third Ministry o Health. Nor does the present Bill seek materially to chang the position. It certainly invokes the assistance of the loca education and sanitary authorities at the will of the Hom Secretary. But it actually deprives the local sanitar authorities of their present responsibility for the sanitatio of workshops. The term factory is to include workshops an workplaces, and so the Home Secretary is responsible fo the whole administration of the Act, and the gradual devolu tion of powers to the local authorities, instituted in 1901, i left to his discretion to rescind or to develop as he, in hi successive incarnations, may think fit. Instead of th "certifying surgeon" we are to have the "appointe doctor" throughout, and his appointment and remuneratio is entirely in the Home Secretary's hands. He may, of course be the local school medical officer or medical officer of health but he seldom will be so, except where the Home Secretar delegates his powers in any area to one local authority o another. At the will of the Home Office, then, the medica officer of health may be more generally barred from th workshops than ever.

Defects of the Present System.

Who is the Inspector? Who is he, indeed, to whom in actual practice the whole health of the nation in its industrial life is committed? Is he medically trained? In a few cases only. Is he trained as a sanitary inspector? Or is he an engineer, trained only to look on accidents as due to bad machinery or preventable negligence? With few exceptions, one cannot believe his attitude of mind is as helpful to the main purpose of factory legislation as the medical officer of health, school medical officer, or sanitary inspector.

And he works from Whitehall or at least from a centre covering a large area, and the supervision of certain special industries—as of certain diseases—over a large area is obviously essential. But what can he know intimately of the personnel in the factory, employer, management or employed, and of the ways in which they interpret the regulations? Would it not be of value to bring the local authorities and their trained officials generally into the system?

---

* Abstracted from a paper read to the Section of Industrial Hygiene at the Congress of the Royal Sanitary Institute, held in Liverpool, July 14th to 19th, 1924.

[1] Figures revised for England and Wales, 1890–2.

How can the lay inspector decide when re-examination of a young person by a doctor is required? Yet under Clause 92 of the new Act, the whole responsibility continues to rest with him. And over and over again time alone can show if a young person is fit for the particular industry for which he has been passed by the appointed doctor; the proof of the pudding is in the eating.

And how is liaison established with the school medical officer, where the Home Secretary has not delegated his powers to the local authority; with the tuberculosis officer with infectious disease in the area; with home conditions? No, at present the medical officer of health and the whole health system of the country are barred from the factories and workshops. And the reason of their being barred is that the Factory Code has grown up in a separate groove, and employers feel safer in this groove, and no Government has the enterprise to establish a comprehensive system of health promotion in this country, as intended in the creation of the Ministry of Health.

Moreover, as one of the most distinguished and experienced authorities of the day expresses it: "Factory administration is the great example of centralised Government without any corresponding local Public Health administration, except in minor matters. On some points it would be easy to indict it; on others it has been a valuable safeguard against local inertia or corruption, and it has enabled large views sometimes to be taken."

The Alternative.

It will be recognised that under the new Bill the Home Secretary has power to make valuable experiments in devolving certain powers to local authorities. But it would surely be of value if he could further devolve all his powers under the Bill to certain county borough councils, willing and able to undertake them, under the central supervision of the experienced inspectors of the Home Office, comparable to the control of local authorities by the Ministry of Health and Board of Education. This would be a useful and, I believe, a safe experiment, which would work well in the interest of employers and employed, and would benefit considerably the health of the general community. Further devolution might follow in course of time to the councils of counties, of boroughs, and of the larger urban districts. But until county councils are given supervising powers in connexion with health, this devolution must be incomplete. For the councils of the smaller districts would not for the most part be capable of undertaking the responsibility and giving the constructive help required. The district medical officer of health and sanitary inspector must, it would seem, continue to be barred from the factories, unless, and until, the system of local government is overhauled, as I hope it may be before long, and a proper county system evolved with suitable allocation of interests, supervision and organic coöperation between the county and its constituent districts. By then it is to be hoped that future medical officers of health and sanitary inspectors will be taught more of industrial hygiene than we were 30 years ago.

As to the Ministries, it would be impossible to transfer the Factory Department of the Home Office to the Ministry of Health, unless the latter were to be relieved of some of its work, not connected with health, such as local government control. It has also been suggested that housing should be transferred to the Board of Works. But these transfers cannot be lightly undertaken. Nor is piecemeal reorganisation of the departments sound. In the interests of the national health we must consider the universal grip that health considerations must have on every section of governmental responsibility. In this view it seems clear that the general conclusion of Lord Haldane's Committee on the Machinery of Government holds good. Every ministry must, for instance, have its department of finances; and most must have a department of health and welfare. The analogy of the army again is useful; for the Army Medical Service not only has complete control of the Royal Army Medical Corps, but also has technical control of the medical and sanitary personnel, to whatever formation, regiment, battery, army corps, or depôt it may be attached; and the Director-General, Army Medical Service, is responsible for advising and therefore collecting all information as to the health of any unit or man in the army. But the commanding officer of each unit or formation is primarily responsible for the health of the men under him, and for the immediate command of medical and sanitary personnel attached.

So, it seems clear, must the health services of civil government be gradually developed. I would see all medical and sanitary personnel recruited and controlled throughout their career and allotted to the several services of the Government departments by the Ministry of Health, to whom they should be technically responsible. But each Government department should have its own health section, as it has its own section of finance, an integral part of that Ministry with direct access to the Ministers, and the Minister in charge would be held responsible for the application of services in such a way as to assist him in the discharge of his responsibilities in connexion with health. The collateral, technical chain of relation between the personnel and the Minister of Health would bring that Minister and his department into intimate relation with the whole activities of national life and would make him in fact, what hitherto he has been partially in fact, but largely only in name, the head and centre of a complete system of national health.

Anyone daring to suggest that this system is complicated, unpractical, should be referred to the army, where a similar, clear, and definite division of responsibility proved of infinite value under the acid test of the late war. It is the only solution.

PUBLIC HEALTH IN BIHAR AND ORISSA.

IN THE LANCET of July 12th (p. 100) we dealt with certain portions of the last official Public Health Report from Patna, but other aspects of the conditions in Bihar and Orissa deserve notice.

The "Special Epidemic Reserve."

A "Special Epidemic Reserve" of 100 vaccinators was entertained from April to September for cholera and other epidemic duty, the work done (disinfection, treatment of wells, and the use of simple remedies) being very satisfactory and much appreciated. A cholera survey of the local conditions in four *thanas* of Cuttack district, where there was undue prevalence of the disease, was also started. Small-pox caused 2560 deaths, showing a mortality of 0·07 per 1000, compared with 0·2 in the previous year and 0·3 in the quinquennium. No district returned a higher ratio than 0·2 (in Purnea and in Singbhum), and in Angul there was not a single fatal case. "Vaccination is neither compulsory nor free. . . . It would, therefore, appear to be wise and proper to organise the work more effectively, and to make vaccination compulsory and free, in order to get the whole population protected, and thus abolish a disease which is of all diseases the most easily and cheaply preventable." As to the justice of this opinion there can be no doubt. There was a general fall in the mortality from "fevers" (17·0 deaths per 1000, compared with 22·6 in 1921 and 23·4 in the decennium). In Puri district of Orissa division (bordering on the Bay of Bengal) the lowest ratio was recorded (8·6); in Angul district of the same division (but inland) the ratio was 19·6; and in Palamau (Chota Nagpur) 22·1. Colonel Ross does not consider "that it is practicable to prevent malaria, or to reduce it permanently, or on any large scale, by the use of quinine"; he believes that "the adoption of non-productive anti-malarial operations, such as draining, levelling, filling hollows and oiling water surfaces is also not a feasible means of prevention on a large scale over an enormous area. . . . It is therefore, in my opinion, a waste of time to discuss and advocate the use of such measures, except in special cases. . . . What is wanted is a policy of malarial prevention, which will pay its own way. . . . Such a policy is possible; it is already being carried out in Italy and in Spain. It consists in combining agricultural improvement with sanitation, by draining or flooding marshes and wet lands in a scientific manner, so as to produce larger crops, and at the same time to reduce the breeding of transmitting mosquitoes and the spread of malaria. It improves the health of the people and their prosperity at the same time."

Plague Mortality.

The total deaths from plague numbered 15,066, giving a ratio of 0·4 per 1000, the same as in 1921, but much lower than that of the decennium (1·0 per 1000). Orissa and Chota Nagpur divisions were quite free, also Purnea and Santal Parganas districts in Bhagalpur division. The highest incidences were recorded in Muzaffarpur, Saran, and Darbhanga districts, where the deaths returned were 1·3, 1·5, and 1·6 per 1000 respectively. In the rural areas the ratio was 0·4, Saran, Darbhanga, and Muzaffarpur recording mortalities of 1·6, 1·4, and 1·2 respectively. In the towns the mortality was 1·1 per 1000, the small town of Lalganj in Muzaffarpur district suffering most (17·3), and Darbhanga next (10·5). Colonel Ross considers that "the permanent separation of the rats from the people is the only permanent measure of prevention." This makes it an "economic question," which for this province means agricultural improvement.

Dysentery and diarrhœa caused 18,037 deaths, giving a ratio of 0·5 per 1000, as compared with 0·9, the decennial average. As usual, these affections were most prevalent in Orissa division, where the mortality was 2·7 per 1000. The districts of Cuttack and Puri suffered most with death ratios of 3·7 and 3·4 per 1000. In the rural areas of the province the mortality was 0·5, while in the towns it was

0·9 per 1000. Among the former Cuttack and Puri showed the same incidence as for the respective districts *including* the towns—viz., 3·7 and 3·4: No other rural area in the whole province showed an incidence higher than 0·9 per 1000, except Sambalpur (2·1). The report states that "the prevalence of dysentery and diarrhœa in Orissa is probably associated with the climatic conditions, and is to a large extent due to the bad state of the water-supply in many parts of this division" [Orissa]. It might be suggested that climatic conditions have little influence as compared with a bad water-supply, and that the public health authority is undoubtedly responsible for remedying this latter defect. Investigations as to the prevalence of hookworm disease have been carried out in this as well as in other provinces, and show that from 50 to over 70 per cent. of the persons examined were affected. Its prevention "entails both the treatment of infected persons and an alteration in the habits of the people, requiring them to abandon the general practice of relieving themselves in the fields, and to take to the use of latrines," so as to avoid conveyance of infection; "treatment alone is largely a waste of time."

School medical inspection has resulted in the examination of 14,476 pupils, and its usefulness is becoming better known and more appreciated. At the Sanitary Laboratory 1013 chemical and bacteriological examinations were carried out by Dr. K. N. Bagchi and his assistant, a considerable amount of food adulteration being detected. In the engineering branch of the Public Health Department several schemes for water-supply and drainage have been, or are being, carried out; but Mr. J. R. Taylor, M.I.C.E., superintending engineer, considers that the present staff of *three* gazetted officers in this branch is insufficient; and that "the department should be reorganised and brought into line, so far as possible, with that of the Public Works Department. The improvement of public health is certainly one of the most crying needs of the country, and it is far from satisfactory that so important a branch as that of the engineering department should be hampered by its staff being overworked with unsatisfactory conditions of service and low pay." With an area of over 83,000 square miles, and a population of 34,000,000 to care for, there would appear to be no possible difference of opinion on this matter.

Vaccination Report.

The triennial report on vaccination[1] "for the years 1920-21, 1921-22, and 1922-23," by which are meant the periods from April 1st to March 31st, states that the operations performed each year numbered, on an average, 1,001,072, as compared with 1,041,667 in the preceding triennium; the primary operations averaged 946,781, and the revaccinations 54,291. The decrease is attributed to political unrest and active interference with the work of the staff. "It appears, however, that the tide is on the turn, and that the difficulties experienced are gradually becoming fewer and less serious." The percentage of success in the operations was satisfactory, being 96·29 in 1920-21, and 98·26 and 98·32 in the succeeding periods. But of the 1,081,900 children available for vaccination in the year 1922-23, only 331 per 1000 were vaccinated, against 396 per 1000 in the previous year. In the municipal towns, out of 30,006 infants available, the vaccinated numbered 13,567, leaving 16,439 unprotected. Colonel Ross concludes his report with the statement that the work of the period under review has been considerably interfered with by political agitation and discontent among the vaccinators, "owing to obstruction in their work and difficulties in realising their fees." They are underpaid. "There is serious risk of the province relapsing into an unvaccinated state. . . . A change of policy is urgently needed, introducing free and compulsory vaccination throughout the province, and making the vaccinators paid servants instead of giving them licences to take fees from the people." It is to be hoped that the provincial authorities will give effect to these recommendations as early as is practicable.

THE MENTAL HOSPITAL OF SYRIA.

To those not familiar with the origin and work of the Lebanon Hospital for Mental Diseases at Beyrout the report of the hospital for 1923-24 should be of unusual interest. Until its foundation by the late Dr. Theophilus Waldmeier in 1900 there was no provision of any sort for the care of the insane in the whole of Syria. There is probably no other place outside the Orient where a person mentally afflicted receives so little consideration from the general public, or where he will more readily be forced into the realm of incurables. In the East it is the popular belief that those who suffer from mental disease are *mejnun*, or possessed by a demon, and numerous methods are adopted by the ignorant and superstitious to cast him out. For instance, a cross is often burnt with a hot iron on the head of insane men and women in hope of "exorcising the demon." In some places such unfortunates, especially women, are kept in some lonely and dark cave until they die. Others are sent, according to what religion they may profess, to some religious shrine, where they are treated as being "possessed" and subjected to various forms of exorcism. The Lebanon Hospital remains the only mental hospital in that country, and receives patients of a strange variety of races—Christian, Jewish, and Moslem alike—from a wide area of the Near East. Funds are provided by committees in various European countries and in America. The income is also maintained by grants from various local authorities towards the maintenance of their pauper patients. Damascus recently withdrew their chronic insane, with the intention of attempting to maintain them in Damascus itself at a cheaper rate, but it is believed that this experiment is proving a failure.

In all 236 patients were under treatment last year, of whom 131 were new admissions, from which it may be gathered that the hospital is a place of treatment for acute cases rather than a mere refuge for the destitute and chronic insane. Complete recoveries numbered 26, and 41 left much improved. There are no striking features in the table of ætiology, but this is incomplete, because local government authorities cannot be persuaded to supply even the scantiest information as to the patients they send. "To get them speedily admitted into the hospital, and thus away from causing further annoyance, is about the extent of the interest bestowed on them, and a shrug of the shoulders the reply to my request for details."

An abundant water-supply has now been obtained by sinking a well, a fact the importance of which will be appreciated when it is known that all water was previously purchased from outside, and that a supply is necessary to enable the land belonging to the hospital to be cultivated. Students from the American University at Beyrout are now attending lectures and clinical demonstrations at the hospital. "Such instruction has not been given to these students before, and as these are the men who will be scattered as doctors all over the East, enlightened ideas and skilled methods of treatment will thus become widely diffused through these lands."

The staff consists of the director, Dr. H. Watson Smith, and a British head attendant, steward, matron, and assistant matron; the nurses are local Syrians.

AUTOMATIC GAS-BAG PRESSURE CONTROL.

Messrs. Coxeter and Son, Ltd., of 171–175, Pancras-road, London, N.W., have sent an account of an apparatus which comprises twin metal levers placed one on each side of the gas bag. These, when forced apart by the expanding bag, compress the feed tube, causing back pressure in a pressure-reducing valve attached to a N_2O cylinder, thus cutting off the gas. The bag control is fitted with a spring, the tension of which can be altered with one hand in order that any desired pressure can be maintained in the bag. When gas is allowed to escape from the bag the restriction on the rubber bag is relaxed and gas again flows automatically from the cylinder. The bag is maintained adequately full without any attention from the anæsthetist. Gas only flows from the cylinder during inhalation, thus saving gas, and this without any action on the part of the anæsthetist. The bag control is very simple in construction, and the claim is made that it is practically impossible for it to get out of order.

THE "HYJAX" WATER-CLOSET SEAT LIFTING APPARATUS.

THIS is an appliance for raising or lowering a closet seat and is worked by means of the foot. It consists of a pedal operated lever connected with the closet seat and provided with a compression cylinder for controlling its descent. One great advantage of the apparatus from an hygienic point of view is that it obviates the necessity for handling the seat, while there is no risk of breaking the basin by the accidental fall of the seat. The work of the housemaid in emptying slops is also simplified. The apparatus, which costs 45s., is on view at Messrs. John Bolding and Sons, Ltd., Grosvenor Works, Davies-street, London, W. 1, from whom it can be purchased.

Arrow.—The risk may be small, but the procedure should never occur. The transfers should always be effected by damping off and using fresh gum. The second question depends upon too many circumstances to make a reply possible.

L. C. B.—The Report of the Departmental Committee appointed to Inquire into Certain Matters Relating to the Diet of Patients in County and Borough Mental Hospitals, abstracted in THE LANCET of July 12th, can be obtained from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, price 6*s*. 6*d*.

Arris and Gale Lecture

ON

FURTHER RELATIONSHIPS OF
DISEASES OF THE GALL-BLADDER
TO THE SECRETORY FUNCTIONS OF THE STOMACH AND PANCREAS.

Delivered at the Royal College of Surgeons of England on May 2nd, 1924,

BY H. ERNEST GRIFFITHS, M.S. LOND.,
F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; DEMONSTRATOR OF ANATOMY, ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL; SURGEON TO THE ALBERT DOCK HOSPITAL; ASSISTANT SURGEON TO THE ALL SAINTS' HOSPITAL.

ANATOMY AND PHYSIOLOGY.

IN a Hunterian lecture[1] on this subject delivered last year I endeavoured to explain at some length the various intricate lymphatic and nervous connexions between the gall-bladder, stomach, duodenum, and pancreas. To summarise: The lymphatic vessels of the gall-bladder are conducted downwards along the common bile-duct, and anastomose with those of the first part of the duodenum and the head of the pancreas before terminating in the retro-pancreatic lymph glands. A route of possible infection is thus readily demonstrated between the gall-bladder, duodenum, and pancreas.

The vagus is the motor and secretory nerve to the gall-bladder and bile passages, and is inhibitory to the sphincter of the ampulla of Vater. The sympathetic, deriving its fibres from the ninth right intercostal segment, is the sensory nerve to the gall-bladder and ducts, and is inhibitory to the muscular wall but supplies the motor filaments to Oddi's sphincter. Thus stimulation of the vagus causes emptying of the gall-bladder through a relaxed sphincter, and stimulation of the sympathetic causes closure of the sphincter and filling of the lax-walled gall-bladder with bile. The vagus in the stomach is again the motor and secretory nerve, and is inhibitory to the pyloric sphincter. The sympathetic derived from the fifth, sixth, seventh, eighth, and ninth thoracic segments is inhibitory to the muscle in general, but motor to the pyloric sphincter. The ninth intercostal segment is mainly responsible for the contraction of the pylorus. The pancreas derives its nerve-supply from both sympathetic and vagus. Stimulation of the vagus causes profuse thin secretion from the pancreas, whereas stimulation of the sympathetic is followed by a small but thick secretion. The sympathetic filaments of the pancreas are mainly derived from the ninth thoracic segment of the cord. With the close developmental origin and nervous association of the gall-bladder, pancreas, pylorus, and first and second parts of the duodenum it must be expected that in their physiological actions and pathological reactions they are closely allied.

Clinically, this is perhaps best exemplified by pylorospasm. Irritation of the mucous membrane of the gall-bladder causes a reflex irritability of the vagus which is most marked by its action in the stomach, where an increase in the amount and acidity of the gastric juice is produced, associated with relaxation of the pylorus and regurgitation from the duodenum. Whereas, in the majority of cases the vagus reflex is the more marked, in others the sympathetic reflex is more evident. In this type of case the inflammation is generally less chronic. As would be expected, it is shown by increased action of that portion of the sympathetic derived from the ninth thoracic nerve. There is a spasm of the ampulla of Vater and relaxation of the gall-bladder walls with consequent dilatation of the viscus. In the stomach there is a spasm of the pylorus, but as the ninth thoracic segment supplies only the pylorus, there is no sympathetic effect on the remainder of the stomach, and the vagus reflex remains unchecked, causing hyperchlorhydria and contraction of the organ. The first and second parts of the duodenum are dilated and the pancreatic secretion is concentrated but small. This condition is clinically known as pylorospasm, and although in the majority of cases the irritating focus is in the gall-bladder, it may occur anywhere in that portion of the digestive tract where the terminal filaments of the sympathetic derived from the ninth thoracic segment are found—namely, gall-bladder, bile-ducts, pylorus, the first and second parts of the duodenum, and the pancreas.

METHODS OF INVESTIGATING SECRETIONS OF THE STOMACH AND PANCREAS.

In all the experimental work on secretions I have been associated with Dr. Mackenzie Wallis, who has conducted the chemical investigations. It has been found impossible to perform each test on any individual patient; in the first place, the demand for hospital beds is so great that no patient can be kept waiting for operation for sufficient time, and in the second place, one did not feel justified in submitting patients to the discomfort of repeated examinations with the stomach and duodenal tubes.

Analysis of External Secretions.

In the majority of our cases we have analysed the one-hour test-meals. A standard meal of one pint of weak tea without sugar or milk and 2 oz. of toast is given after a 12 hours' fast and the contents of the stomach drawn off through a stomach-tube one hour later. The result is analysed for free HCl, combined HCl, mineral chlorides, and digestive activity. This method has the advantage of simplicity and causes the patient the minimum amount of discomfort.

Fractional Test-meal.—A narrow bore tube is passed into the fasting stomach and the residual secretion is aspirated. With the tube remaining in position the patient is given about a pint of oatmeal gruel. A quarter of an hour later 20 c.cm. of fluid are aspirated for analysis. Further specimens are collected at intervals of a quarter of an hour up to the end of the first hour, and then at half-hourly intervals until two and a half hours after the meal was given. The specimens are analysed for free and combined HCl, mineral chloride, and bile.

Duodenal Tube.—It has been claimed by Meltzer[2] that a solution of magnesium sulphate applied directly to the duodenum causes relaxation of the walls of the gut and of the sphincter muscle of the ampulla of Vater, and almost simultaneously a contraction of the gall-bladder. The flow of bile into the duodenum is thus stimulated. Lyon,[3] basing his experiments on this fact, first described a method of measuring the rate of flow of bile into the duodenum after the injection of magnesium sulphate, and also of segregating the bile, so that the fluid coming from the common bile-duct, gall-bladder, and ducts in the liver might be collected and examined separately. The patient is examined after a 15 hours' fast, the mouth is washed out with a solution of 1/1000 potassium permanganate followed by a weak solution of zinc chloride, and then a sterile duodenal tube passed into the stomach and some of the contents aspirated into a sterile vessel. The stomach is now washed out with sterile water, the patient turned on the right side, and the hips slightly raised by a pillow. The patient is instructed slowly to swallow the tube to the duodenal point, meanwhile drinking a glass of water. It usually takes about 15 to 45 minutes for the tube to pass through the pylorus. This is recognised by the duodenal tug and by the fact that the liquids, such as broth, swallowed by the mouth are not recoverable through the tube. When the duodenum

0·9 per 1000. Among the former Cuttack and Puri showed the same incidence as for the respective districts *including* the towns—viz., 3·7 and 3·4: No other rural area in the whole province showed an incidence higher than 0·9 per 1000, except Sambalpur (2·1). The report states that "the prevalence of dysentery and diarrhœa in Orissa is probably associated with the climatic conditions, and is to a large extent due to the bad state of the water-supply in many parts of this division" [Orissa]. It might be suggested that climatic conditions have little influence as compared with a bad water-supply, and that the public health authority is undoubtedly responsible for remedying this latter defect. Investigations as to the prevalence of hookworm disease have been carried out in this as well as in other provinces, and show that from 50 to over 70 per cent. of the persons examined were affected. Its prevention "entails both the treatment of infected persons and an alteration in the habits of the people, requiring them to abandon the general practice of relieving themselves in the fields, and to take to the use of latrines," so as to avoid conveyance of infection; "treatment alone is largely a waste of time."

School medical inspection has resulted in the examination of 14,476 pupils, and its usefulness is becoming better known and more appreciated. At the Sanitary Laboratory 1013 chemical and bacteriological examinations were carried out by Dr. K. N. Bagchi and his assistant, a considerable amount of food adulteration being detected. In the engineering branch of the Public Health Department several schemes for water-supply and drainage have been, or are being, carried out; but Mr. J. R. Taylor, M.I.C.E., superintending engineer, considers that the present staff of *three* gazetted officers in this branch is insufficient; and that "the department should be reorganised and brought into line, so far as possible, with that of the Public Works Department. The improvement of public health is certainly one of the most crying needs of the country, and it is far from satisfactory that so important a branch as that of the engineering department should be hampered by its staff being overworked with unsatisfactory conditions of service and low pay." With an area of over 83,000 square miles, and a population of 34,000,000 to care for, there would appear to be no possible difference of opinion on this matter.

Vaccination Report.

The triennial report on vaccination[1] "for the years 1920-21, 1921-22, and 1922-23," by which are meant the periods from April 1st to March 31st, states that the operations performed each year numbered, on an average, 1,001,072, as compared with 1,041,667 in the preceding triennium; the primary operations averaged 946,781, and the revaccinations 54,291. The decrease is attributed to political unrest and active interference with the work of the staff. "It appears, however, that the tide is on the turn, and that the difficulties experienced are gradually becoming fewer and less serious." The percentage of success in the operations was satisfactory, being 96·29 in 1920-21, and 98·26 and 98·32 in the succeeding periods. But of the 1,081,900 children available for vaccination in the year 1922-23, only 331 per 1000 were vaccinated, against 396 per 1000 in the previous year. In the municipal towns, out of 30,006 infants available, the vaccinated numbered 13,567, leaving 16,439 unprotected. Colonel Ross concludes his report with the statement that the work of the period under review has been considerably interfered with by political agitation and discontent among the vaccinators, "owing to obstruction in their work and difficulties in realising their fees." They are underpaid. "There is serious risk of the province relapsing into an unvaccinated state. . . . A change of policy is urgently needed, introducing free and compulsory vaccination throughout the province, and making the vaccinators paid servants instead of giving them licences to take fees from the people." It is to be hoped that the provincial authorities will give effect to these recommendations as early as is practicable.

THE MENTAL HOSPITAL OF SYRIA.

To those not familiar with the origin and work of the Lebanon Hospital for Mental Diseases at Beyrout the report of the hospital for 1923-24 should be of unusual interest. Until its foundation by the late Dr. Theophilus Waldmeier in 1900 there was no provision of any sort for the care of the insane in the whole of Syria. There is probably no other place outside the Orient where a person mentally afflicted receives so little consideration from the general public, or where he will more readily be forced into the realm of incurables. In the East it is the popular belief that those who suffer from mental disease are *mejnun*, or possessed by a demon, and numerous methods are adopted by the ignorant and superstitious to cast him out. For instance, a cross is often burnt with a hot iron on the head of insane men and women in hope of "exorcising the demon." In some places such unfortunates, especially women, are kept in some lonely and dark cave until they die. Others are sent, according to what religion they may profess, to some religious shrine, where they are treated as being "possessed" and subjected to various forms of exorcism. The Lebanon Hospital remains the only mental hospital in that country, and receives patients of a strange variety of races—Christian, Jewish, and Moslem alike—from a wide area of the Near East. Funds are provided by committees in various European countries and in America. The income is also maintained by grants from various local authorities towards the maintenance of their pauper patients. Damascus recently withdrew their chronic insane, with the intention of attempting to maintain them in Damascus itself at a cheaper rate, but it is believed that this experiment is proving a failure.

In all 236 patients were under treatment last year, of whom 131 were new admissions, from which it may be gathered that the hospital is a place of treatment for acute cases rather than a mere refuge for the destitute and chronic insane. Complete recoveries numbered 26, and 41 left much improved. There are no striking features in the table of ætiology, but this is incomplete, because local government authorities cannot be persuaded to supply even the scantiest information as to the patients they send. "To get them speedily admitted into the hospital, and thus away from causing further annoyance, is about the extent of the interest bestowed on them, and a shrug of the shoulders the reply to my request for details."

An abundant water-supply has now been obtained by sinking a well, a fact the importance of which will be appreciated when it is known that all water was previously purchased from outside, and that a supply is necessary to enable the land belonging to the hospital to be cultivated. Students from the American University at Beyrout are now attending lectures and clinical demonstrations at the hospital. "Such instruction has not been given to these students before, and as these are the men who will be scattered as doctors all over the East, enlightened ideas and skilled methods of treatment will thus become widely diffused through these lands."

The staff consists of the director, Dr. H. Watson Smith, and a British head attendant, steward, matron, and assistant matron; the nurses are local Syrians.

AUTOMATIC GAS-BAG PRESSURE CONTROL.

Messrs. Coxeter and Son, Ltd., of 171–175, Pancras-road, London, N.W., have sent an account of an apparatus which comprises twin metal levers placed one on each side of the gas bag. These, when forced apart by the expanding bag, compress the feed tube, causing back pressure in a pressure-reducing valve attached to a N_2O cylinder, thus cutting off the gas. The bag control is fitted with a spring, the tension of which can be altered with one hand in order that any desired pressure can be maintained in the bag. When gas is allowed to escape from the bag the restriction on the rubber bag is relaxed and gas again flows automatically from the cylinder. The bag is maintained adequately full without any attention from the anæsthetist. Gas only flows from the cylinder during inhalation, thus saving gas, and this without any action on the part of the anæsthetist. The bag control is very simple in construction, and the claim is made that it is practically impossible for it to get out of order.

THE "HYJAX" WATER-CLOSET SEAT LIFTING APPARATUS.

THIS is an appliance for raising or lowering a closet seat and is worked by means of the foot. It consists of a pedal operated lever connected with the closet seat and provided with a compression cylinder for controlling its descent. One great advantage of the apparatus from an hygienic point of view is that it obviates the necessity for handling the seat, while there is no risk of breaking the basin by the accidental fall of the seat. The work of the housemaid in emptying slops is also simplified. The apparatus, which costs 45*s*., is on view at Messrs. John Bolding and Sons, Ltd., Grosvenor Works, Davies-street, London, W. 1, from whom it can be purchased.

Arrow.—The risk may be small, but the procedure should never occur. The transfers should always be effected by damping off and using fresh gum. The second question depends upon too many circumstances to make a reply possible.

L. C. B.—The Report of the Departmental Committee appointed to Inquire into Certain Matters Relating to the Diet of Patients in County and Borough Mental Hospitals, abstracted in THE LANCET of July 12th, can be obtained from H.M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, price 6*s*. 6*d*.

considered evidence of deficiency of trypsin. Solomon's test depends upon estimating the amount of lecithin found in the stool after an egg diet. Müller's test for trypsin consists in examination of the stool for ferment after a test-meal. A few drops of the emulsion of the stool are placed on a Petri dish of coagulated blood serum and incubated. The presence of active ferment is shown by the appearance of pits in the coagulum.

Animal Experiments.

Many animal experiments have been devised to show the results of infection of the pancreas in its normal condition, and also when there is interference with its external secretion by ligature of one or both ducts. Truehart found bacteria present in the normal pancreatic duct in 5 out of 223 cases. Experimentally organisms have been introduced into the pancreatic duct directly with a syringe, or the gall-bladder or ducts have been inoculated and the pancreas infected secondarily. Efforts have been made to force infected material into the main pancreatic duct from the duodenum by increasing pressure in the bowel. More success has been obtained in this direction by first causing trauma of the ampulla of Vater, or by passing a thread through the papilla, allowing at least a capillary communication between the duct and the duodenum. Bile and solutions of bile-salts have been injected into the pancreas under different conditions, such as after ligature of one or both pancreatic ducts. Reference to the details and the results of these experiments will be made later.

CORRELATION OF SYMPTOMS.

Alteration in the secretion of the stomach and pancreas is often associated with pain, and in the Hunterian lecture already referred to I endeavoured to make an exhaustive analysis of the types of pain met with in cases of inflammatory lesions of the gall-bladder. Biliary dyspepsia, accompanied as it is by flatulence, is an indication of disordered gastric secretion, and generally denotes hyperacidity. Another symptom of the increase of free HCl commonly associated with gall-stones is referred pain in the left scapular region.

Vomiting of several different types occurs in disorders of the gall-bladder, two of which are definitely associated with disordered secretion of the companion organs. In biliary dyspepsia vomiting may occur after a full meal, but it is not as a rule accompanied by nausea. It is generally small in quantity and of a watery regurgitant type. Occasionally it is copious, resulting in evacuation of the stomach and affording the patient complete relief from pain. Increased gastric acidity is mainly responsible for this type of vomiting. Vomiting that occurs at periodic intervals usually unassociated with any gross disturbance of the gall-bladder and bile-passages, but which may occasionally follow an attack of cholecystitis, is often an indication of pancreatic insufficiency. There is generally nausea present in these cases, but a mild diarrhœa is a constant feature, the stools being fatty and undigested. The attack generally lasts for several days, in more severe cases extending into weeks. Wasting is a constant feature in cases of long duration. The character of the stool, with the marked increase of undigested fat, is symptomatic of pancreatic insufficiency, of which other evidence is given by the increased diastase content of the urine, indicanuria, and sometimes a transient glycosuria. This class of case is due to a catarrhal pancreatitis from invasion of the pancreas with organisms which in the majority of cases appear to be derived from the gall-bladder. During the attack there is definite evidence of diminution of the external, and often of the internal, secretion of the pancreas.

Hyperchlorhydria and Regurgitation.

Working with the one hour test-meal, Dr. Mackenzie Wallis and I have found hyperchlorhydria associated with regurgitation in 99 per cent. of cases of cholecystitis with or without the presence of gall-stones.

A review of the literature of the subject shows that absolutely contradictory results have been obtained by different investigators. Düttman states that irreparable hypoacidity and hypochlorhydria are entailed by inflammation of the biliary passages and they persist in more than 50 per cent. of the patients after operation. The duration of the inflammation and its degree are reflected in the intensity of the secretory deficit in the stomach.[5] Cohn's tables show hypoacidity in the stomach with gall-stone disease in 87 per cent. of 44 cases and in 100 per cent. of 63 cases after removal of the gall-bladder. This constant achlorhydria seemed to be permanent after cholecystectomy. He traced in 11 cases the decline in gastric-juice secretion before operation and after the removal of the gall-bladder. The ferment production he did not find altered.[6] Ohly examined the gastric juice in 200 patients suffering from cholelithiasis. He found that early uncomplicated cases have hypoacidity, while chronic cases present usually subacidity or anacidity. The subjective disturbances localised in the stomach and the amount of mucus present in some patients of the second group seem to indicate an independent chronic gastritis, which might have been the primary affection.[7]

From most of the figures published it will be seen that in the majority of cases of cholelithiasis and cholecystitis the examination of the one-hour test-meal shows a deficiency in free acid. This may be due to two causes; first, there may have been less hydrochloric acid secreted by the stomach—a true hypochlorhydria—which may even have amounted to achlorhydria; second, the HCl may have been secreted in normal or even greater amounts but have become partially neutralised after secretion. This second cause is probably the real explanation of the apparent hypochlorhydria in gall-stone cases reported so frequently. In typical test-meals the figures are:—

—	Normal.	Hyperc.	Hypoc.	Regurg.
Total chlorides	0·32	0·42	0·25	0·42
Free HCl	0·02	0·02	0·01	0·01
Protein HCl	0·23	0·29	0·18	0·20
Mineral chlorides ..	0·07	0·11	0·06	0·20

Hyperc. = hyperchlorhydria. Hypoc. = hypochlorhydria.
Regurg. = regurgitation.

In a true hypochlorhydria, although the free HCl is diminished in quantity, the mineral chlorides remain about normal, and in hyperchlorhydria the HCl is increased, but the mineral chlorides are nearly normal. In the last type of case, however, the free HCl is markedly diminished, and there is a corresponding increase in the mineral chlorides suggesting that they were increased at the expense of the free HCl—i.e., that the free acid was first secreted and then neutralised. If this explanation be accepted it would seem that there are three definite types of test-meal results: (1) those showing neutralisation of free acid—regurgitant type, comprising 90 per cent. of our cases; (2) those showing true hyperchlorhydria, 8 per cent. of our cases: (3) those showing true hypochlorhydria, 2 per cent. of our cases. A further examination of type 4 shows that an excess of HCl had been secreted in the majority of cases, showing that there was hyperchlorhydria before neutralisation took place.

It is necessary, then, first to consider why in the majority of cases of gall-bladder disease there is increased secretion of HCl, and second why this acid should be largely neutralised whilst still in the stomach. The causes of the increased acid secretion may be three: First, that it is part of a general decrease in alkalinity of the body tissues, as might be indicated by the increased amount of cholic acid in is reached a few cubic centimetres of air are forced down the tube with a syringe to dilate the duodenum and prevent injury to the mucosa. The contents of the duodenum are aspirated into a sterile bottle. They are greyish in colour, and thick, from the presence of much mucus. Bile is absent from the fasting duodenum. 50 to 100 c.cm. of 25 per cent. solution of magnesium sulphate are next injected through the tube and then very slowly aspirated into a sterile bottle. Within ten minutes the aspirated fluid is seen to be tinged with yellow, which gradually increases until it is of a pale yellow colour. A third sterile collecting bottle is substituted and aspiration continued until, by watching a window in the tube, the fluid is seen suddenly to change in character, becoming darker in colour and thicker in consistency. This, Lyon states, is due to the contraction and evacuation of the gall-bladder, the proceeding bile being derived from the common bile-duct. It amounts to 50 to 100 c.cm. and is collected in a fourth sterile bottle. The bile is not secreted in a constant stream but in a series of little puffs, this being most apparent when the stream of bile in the extra-hepatic ducts is used up.

[7] A. Ohly: Archiv für Verdauungskrankheiten, September, 1923.

Examination of the Fluid.—In the healthy patient the bile collected through the duodenal tube is free from pus, epithelial cells, and red blood cells. Mucus is present, but in solution. In inflammatory conditions involving the common bile-duct alone—e.g., early catarrhal jaundice—examination of the bile in the third sterile bottle—i.e., bile from the common bile-duct—shows that it is rather thicker than normal and darker in colour; flakes of mucus are plentiful, and examination under the microscope reveals the presence of pus cells and occasionally red blood cells. In pure cases of cholecystitis the bile from the common bile-duct may be normal, but bile from the gall-bladder may be found to be rich in mucus, pus, and columnar epithelial cells; its colour is paler than normal and organisms have been found on culture. In some cases of gall-stones, crystals of cholesterin and bile-salts have been found. In one case described by Lyon several small faceted stones were recovered. There has been considerable discussion as to how the presence of a solution of magnesium sulphate in the duodenum causes a flow of bile. Meltzer's view has already been mentioned—namely, that the salt acts directly on the muscle of the duodenum and reflexly on the muscle of the extra-hepatic bile-passages. It has been claimed that osmosis is responsible for the attraction of the bile into the duodenum, and it is shown that certain other neutral salts may be used in place of magnesium sulphate.

In our work Dr. Mackenzie Wallis and I have paid particular attention to the presence of pancreatic juice in the fluid obtained through the duodenal tube. We were particularly fortunate in our observations on one case of Mr. H. J. Waring's. A married woman of 34 had had intermittent jaundice for six weeks which had now settled down into a jaundice of the progressive type. She had a little pain in the right subcostal region and had complained of slight flatulence. The gall-bladder could not be palpated, and Murphy's sign was negative. A preliminary diagnosis of gall-stones in the common bile-duct or new growth of the bile-ducts was made. A duodenal tube was passed and some of the contents of the stomach collected. The tube was then passed into the duodenum, which was found to be empty or contained mucus too thick to come up the tube. Magnesium sulphate solution was injected in the ordinary way and some was aspirated at frequent intervals for three-quarters of an hour. Each specimen was almost clear and showed no trace of bile-pigment. The tube was then withdrawn into the stomach and a second specimen of the gastric content obtained. On analysis the duodenal content was found to be very rich in trypsin and lipase, but quite free from bile-pigments and salts. The two stomach specimens contained no lipase. It seems clear, therefore, that there had been a free secretion of pancreatic juice into the duodenum. At operation it was found there was a new growth involving the common bile-duct and the hepatic ducts, but leaving the pancreas and ampulla of Vater clear.

The presence of pancreatic juice in this case cannot be explained by the mechanical action of stimulated muscle or by osmotic action. It appears that the pancreas had definitely been stimulated to secrete, and this implies the liberation of secretin. Apperly and Cameron[4] devised a test by which they claim to estimate the alkalinity of the pancreatic juice and so test the pancreatic efficiency. They state that an acid solution in the stomach induces regurgitation from the duodenum of its alkaline contents to neutralise it, and that the neutralising properties of the saliva, bile, and succus entericus are relatively so small that an estimation of the amount of alkali used up in neutralising the acid may be taken as indicative of the quantity of pancreatic juice secreted. A narrow-bore stomach-tube is passed into the fasting stomach and the contents aspirated, then 250 c.cm. of 0·4 per cent. HCl are passed into the organ. Specimens are drawn off every 15 minutes and titrated for acid, the results being plotted on a curve. Before withdrawing each specimen the contents of the stomach are mixed by filling and emptying the syringe two or three times. The rate of neutralisation gives a rough comparison of the rate of production of pancreatic juice in different people, provided there is no obstruction, organic or tonic, to the normal duodenal reflex.

Chemical Examination of the Blood, Urine, and Stools.

This affords much useful information of the external and internal secretions of the pancreas. It is outside the scope of this lecture to deal with the technical details of the laboratory investigations, and only the main objects of the experiments can be described.

Blood.—Examination of the blood for sugar, diastase, lipase, and cholesterol have been carried out in a number of cases. Excess of sugar and diastase indicate a pancreatic insufficiency. Lipase is generally constant at 0·2–0·3, but where there is inflammatory disease of the biliary passages associated with the formation of gall-stones the cholesterol content shows a well-marked increase.

Urine.—The urine is examined for sugar, diastase, and indican. The detection of sugar in the urine is the oldest test for pancreatic insufficiency; as a quantitive test it has now given way almost entirely to the estimation of blood-sugar. The diastase content of normal urine varies from 10–30 units, with an average of about 22·5. In certain diseases of the pancreas, more especially inflammatory, the diastase content rises considerably, generally being found to vary between 50 and 200 units. In one case of acute hæmorrhagic pancreatitis the figure reached 1000 units. Later I will endeavour to show that an increased diastase is dependent upon disturbed function of the parenchyma, and may reach a high figure without any increase in the blood-sugar, which is generally accepted to be due to interference with the islands of Langerhans. Indicanuria is an indication of intestinal toxæmia, and occurs in all cases of deficiency of the external secretion of the pancreas.

Stools.—Many tests for pancreatic sufficiency have been devised which depend upon examination of the stool for the end-products of pancreatic digestion. Excess of fat, undigested muscle-fibre, particularly muscle nuclei, and the absence of proteolytic ferment are all taken as evidence of a decrease in the amount or the activity of the pancreatic juice. Sahli's test consists of feeding the patient with a gelatin capsule hardened to resist the gastric juice and containing iodoform. This should be digested by the pancreatic juice and iodine detected in the urine and saliva in less than eight hours, delay over that period being through the lymphatic vessels of the head of the pancreas, with the primary focus generally in the gall-bladder. In an apparently undue proportion of cases gall-stones are found in the common bile-duct. Maugauret suggested that this is the result rather than a cause of the pancreatitis, as pressure exerted by the sclerosis of the head on the common bile-duct causes narrowing of the passage and the arrest of the stone. This explanation is accepted by Dever and Ashurst and seems to be the correct one.

---

[4] Med. Jour. of Australia, May, 1923, p. 521.

The clinical manifestations of interference with the external secretion of the pancreas are much less than they are in catarrhal pancreatitis. Diarrhœa is rare, and nausea and vomiting usually occur late. The lack of complete digestion of protein paves the way for considerable intestinal intoxication from the end-products of bacterial decomposition, and these toxins themselves may have some effect in increasing the pancreatic fibrosis. Glycosuria only occurs in fairly advanced cases, but an increase in the diastase content of the urine is almost constant, the figures varying from 35 to 50 units. This raises the point of why the diastase should be increased. The source of diastase is not known, but is certainly not the pancreas, as extirpation of the organ causes a marked increase in the ferment.

It is probable that diastase is activated by some agent that is produced by the pancreas, and that when the pancreas is diseased this agent is decreased in amount and the unactivated diastase collects in excess in the blood, to be excreted in the urine. As the islands of Langerhans are not apparently affected in interstitial pancreatitis it seems probable that the deficiency of the activating agent of the diastase is dependent upon the destruction of the parenchyma, and I suggest that it is from these cells that it is derived.

Acute Pancreatitis.—There has been much speculation as to the cause of acute pancreatitis, and much work has been done experimentally to support different theories. Flexner found that he could produce acute pancreatitis by the injection of bile into the pancreatic ducts. He states that the bile-salts are the destructive agent, and that the inflammation produced is lessened proportionately to the increase in the ratio of colloid to bile-salts in the injected material. He argued, therefore, that in chronic infection of the bile-passages there is a loss of diffusible salts and an increase in the amount of colloid material, and in these cases chronic pancreatitis should be more common than acute. If this be accepted, we must consider the effect of removal of the secretion of the gall-bladder from the bile circulation. This may be the result of cholecystectomy or of disease—e.g., a stone impacted in the cystic duct with the formation of a mucocele. Here the bile secreted into the duodenum is deficient in mucus unless there is a gross infection of the biliary passages. I have no record of a primary attack of acute pancreatitis occurring in such a case. In fact, rather the opposite has been found. In the majority of cases of acute pancreatitis I have seen there has been mild infection of the gall-bladder resulting in an increase in the amount of mucus.

Archibald states that in infected bile the proportion of bile salts to mucus is increased 6 to 12 times, but my experience has been that this is only the case where the gall-bladder has lost its physiological functions through disease. The secreting pressure of the liver is seldom greater than 350 mm. of bile, and that of the gall-bladder is under 300 mm. of bile, but when the intra-abdominal tension is very much raised, as in straining or vomiting, the secreting pressure of the bile may be raised to 1000 mm. Mann experimented to find out whether the pressure under which bile entered the pancreatic ducts had anything to do with the cause of acute pancreatitis. He writes: "If the bile is injected under a pressure of 500 mm., or a pressure greater than the secreting pressure of the liver, and the contraction of the gall-bladder, acute pancreatitis does not occur. If the bile is injected under a pressure of 1000 mm., which was the maximum pressure produced in the common bile-duct—namely, that produced by vomiting—acute pancreatitis may occur, though rarely." Mann's results afford, I think, a very striking explanation of Nordman's experiment on the injection of bacterial cultures into the gall-bladder of a dog after ligature of the pancreatic ducts. He found that when both pancreatic ducts were ligatured the dog died of acute pancreatitis, but when only one duct was ligatured the dog died of cholangitis. The pancreatic ducts in the dog, as is generally the case in the human, have a free communication with each other. It seems certain, therefore, that when both were ligatured the pressure rose in the pancreas to the danger-point and then the infected bile did the rest. When one pancreatic duct remained patent it acted as a safety-valve keeping down the pancreatic pressure to normal, and the infected bile was powerless.

Writing with Mr. H. J. Waring in the *British Journal of Surgery* in January last we said that normally the pancreatic juice is not activated until it reaches the intestine. If, however, trypsinogen be converted into trypsin in the ducts or substance of the organ, rapid destruction of tissue must be expected, producing a condition so like a perforated gastric ulcer that Mayo has spoken of it as "perforation of the pancreas." Activation of trypsin within the gland is the predominant factor of acute hæmorrhagic pancreatitis. A number of reagents found in the body other than enterokinase can activate trypsinogen, chief among them being blood, infected bile, degenerate leucocytes, and certain bacterial toxins. It is probable that trypsinogen is only activated by infected bile when the latter contains pus cells. In the majority of cases of acute pancreatitis the trypsinogen is activated by blood. If blood be the activating agent trauma should be one of the causes of the disease, and this has often been proved. Case 9 in the article already referred to in the *British Journal of Surgery* had acute pancreatitis after a street accident.

Acute pancreatitis is generally a sequel of pancreatic lymphangitis. Here there is already congestion of the pancreas and a tendency to vomit. Now with spasm of Oddi's sphincter, a reflex from the originally infected gall-bladder, there is regurgitation of bile into the pancreatic duct. Vomiting or straining may raise the pressure of the bile, as already explained, to 1000 mm., and at this pressure some bleeding from the congested bile capillaries is bound to occur, causing liberation of the ferment trypsin whose activity is intensified fourfold by the presence of bile. It is not absolutely necessary to have regurgitation of bile to cause hæmorrhage; this may and does occur through sheer congestion.

In these two lectures I have endeavoured to show that when infection occurs in the gall-bladder a train is fired which always lights gastric fireworks, and may end in a pancreatic explosion.

DONATION TO QUEEN'S UNIVERSITY, BELFAST.—At the meeting of the Senate held on July 16th it was announced by Mr. J. H. Stirling, the treasurer, that the executors of the late Mr. J. C. White, formerly Lord Mayor of Belfast, had forwarded the sum of £30,000 as a contribution to the funds of the University. Under the terms of the bequest, of this sum £15,000 are to be devoted to the foundation of a chair in biological chemistry and to the upkeep of that department. The remaining £15,000 are to be devoted to the establishment of a chair or lectureship in bacteriology and to the purposes of that department. The Vice-Chancellor, Dr. R. W. Livingstone, in moving a vote of thanks to the executors, dwelt upon the great importance to the medical school and to the world of the subjects of biochemistry and bacteriology. The former had in recent times assumed a leading place in medicine, and from it there was promise of great advances in the near future. The University has already a lectureship in the subject, and the Royal Victoria Hospital recently added a biochemist to its staff. It is hoped that the benefaction for bacteriology may pave the way for the foundation of a separate chair, distinct from that of pathology, in that subject. This step has been for some time in contemplation.

the blood and the decreased pH of the urine (4·5). Second, that it is a reflex nervous phenomenon. As the vagus is the main secretory nerve of the gall-bladder and stomach, an inflammatory lesion of the former might be expected to cause reflex stimulation of the vagus in the stomach, resulting in a marked increase in the flow of gastric juice and in the percentage of acid. Third, that it is the natural reaction of the stomach mucosa to the presence of foreign alkali.

Rous and McMaster showed that the gall-bladder is capable of concentrating bile ten times in 24 hours, and that during its passage through the cystic duct bile is concentrated two to four times. In this way, although the gall-bladder has only an average capacity of 2½ fluid ounces, it is able to contain the product of concentration of about 30 oz. of bile, and is therefore largely responsible for the fact that in the normal individual bile does not pass directly into the duodenum when secreted by the liver. Bile is stored by the gall-bladder to be secreted when required for the process of digestion. In the diseased gall-bladder, particularly when gall-stones are present, its function as a reservoir for concentrated bile is much impaired, and there is a tendency for bile to trickle down into the duodenum in a constant stream. This may be in part compensated by the activity of Oddi's sphincter, but it seems clear that in many cases there is a leak of bile into the duodenum. Its presence then in the duodenum in the resting stage causes reflex inhibition of the pylorus and regurgitation into the stomach of small quantities of this foreign alkali.

Regurgitation.—The abnormal regurgitation of duodenal contents that occurs during stomach digestion appears to be due to a reflex through the vagus nerve. I have already stated that irritation of the mucous membrane of the gall-bladder causes a reflex irritability of the vagus which is most marked by its action on the stomach, where an increase in the amount and acidity of the gastric juice is produced, associated with relaxation of the pylorus and regurgitation from the duodenum.

Hyperchlorhydria.—True hyperchlorhydria associated with disease of the gall-bladder appears to depend upon the fact that in these cases the regurgitation into the stomach occurs in less quantity than normal, and the pancreatic juice, itself the main factor in neutralising acid chyme, may be diminished in quantity and alkalinity. It is due to a reflex through the sympathetic deriving from the ninth thoracic segment, causing a spasm of the pylorus and Oddi's sphincter. In these cases of pylorospasm there is, as I have already explained, hyperacidity and decreased pancreatic secretion. The pancreatic juice is further held up by the spasm of Oddi's sphincter, so that the possibilities of regurgitation of alkali from the duodenum are reduced to a minimum.

Hypochlorhydria.

True hypochlorhydria occurring in inflammatory lesions of the gall-bladder appears to be due to intercurrent disease, although it occurs regularly in advanced cases of carcinoma of the gall-bladder.

Gastric and Duodenal Ulcer.

The increase in the amount of hydrochloric acid secreted by the stomach might have been expected to be responsible for the presence of gastric and duodenal ulcers in patients suffering from a diseased gall-bladder, and duodenal ulcer particularly has been described both as a cause and result of cholecystitis. In the series of cases which I have examined or whose operation or post-mortem records I have searched the presence of these ulcers has been so rare (two duodenal and one gastric ulcer in 500 cases) as to warrant the statement that they occur only as intercurrent diseases. The presence of the ulcer is generally diagnosed on the clinical history, and the presence of blood in the vomit is taken as pathognomonic, but gastric bleeding is not very infrequent in gall-bladder disease. Woolsey places these figures as high as 5 per cent. I have only come across it three times and in neither case was any gastric lesion discovered at operation, although, of course, the stomach was not opened. Floersheim states that gastric hæmorrhage as an accompaniment of appendix and gall-bladder disease seldom shows any pathological change in the stomach.[8]

CHANGES IN THE PANCREAS ASSOCIATED WITH THE DISEASED GALL-BLADDER.

Catarrhal Pancreatitis.—I have already given a brief description of the clinical features of this disease —periodic attacks of nausea, vomiting, and diarrhœa with bulky stools laden with undigested fat. The attack is nearly always heralded by a bout of shivering and a feeling of vague abdominal discomfort.

If the abdomen be opened during an attack the head of the pancreas and sometimes part of the body are found to be swollen and hyperæmic. It is very evident, therefore, that the condition is due to an inflammatory process; the rise of the temperature preceded by a shivering attack suggesting that it is the result of pyogenic infection. The route by which infection reaches the pancreas in these cases, and indeed the primary focus, may vary, although in the majority of cases it seems clear that the bacteria are carried from the gall-bladder to the pancreas via the lymphatics. In catarrhal pancreatitis the disturbance of the external secretion is far greater than of the internal secretion, and as the attack generally lasts for such a short time and only the proximal part of the organ seems to be affected macroscopically, it seems probable that the main symptoms are due to temporary obstruction rather than to the suppression of secretion. The absence of jaundice in the majority of these cases is proof that the ampulla of Vater is patent; the obstruction must therefore be further back involving the main pancreatic ducts, and may be due to swelling of the mucous membrane of the ducts or to pressure by the swollen pancreatic tissue. If this latter were the case jaundice should be of more frequent occurrence, for the terminal part of the common bile-duct is buried in the head of the pancreas and should be subject to equal pressure. Evidence of disturbance in the internal secretion is given by the alteration of the diastase content of the urine and occasionally by the presence of glycosuria. In a case of a woman of 45, who was under observation for a long period and whose attacks were of frequent and long duration, the diastase unit was usually under 20, although on one occasion it rose to 50. At no time was any trace of sugar found in the urine and the blood-sugar remained normal. An interesting case is described by Seale Harris.[9] An insurance agent, aged 35, came under treatment for diarrhœa. He had had an operation for gall-bladder infection, when the pancreas was found to be enlarged and inflamed. His stools showed azotorrhœa and steatorrhœa. His urine contained a trace of sugar, and his blood-sugar was 700 mg. per 100 c.cm.

Chronic Interstitial Pancreatitis, according to Opie, may be of three types: interlobular, interacinar, and a degenerate lipomatosis. The interlobular seems to be the only variety associated with gall-bladder disease. Macroscopically the head of the pancreas is found to be somewhat enlarged, nodular and hard, resembling carcinoma. In old-standing cases the changes may extend along the whole body of the organ. Microscopically there is found to be a large increase in fibrous tissue involving the interlobular spaces. As the disease advances there is gradual destruction of the parenchyma by pressure or sometimes by direct infiltration with fibrous tissue. The islands of Langerhans, on the other hand, escape for the most part, and by the destruction of alveoli appear to be in greater numbers than normal. When they are affected it seems to be rather by having their blood-supply cut off than by being themselves subjected to pressure. This form of chronic pancreatitis seems to be invariably caused by infection in lactose and saccharose on prolonged incubation, and both produced acid and clot in litmus milk in 11 days. The subculture was more rapid in its action on saccharose than the original culture. The milk control tubes (*a*) uninoculated, (*b*) inoculated with *B. Flexner* V. showed no visible change in 12 days. The organism was non-motile and was negative for production of indol. It was noted that after 24–28 days the lactose and saccharose fluid media tended to become alkaline. Animal experiments will be detailed later.

---

[8] Quoted by W. J. Frick and R. D. Irland, Surg. Clinics of North America, December, 1923.

[9] Amer. Med. Assoc., Nov. 3rd, 1923.

The reactions just described place the bacillus in question outside the Flexner group of dysentery bacilli, apart from the fact that it gave negative results in agglutination tests with *B. Flexner* V, W, X, Y (Oxford), and Z. Excepting the reaction in litmus milk, this T. C. bacillus resembles in "sugar" fermentations, non-motility, and negative indol formation the Sonne III. type of dysentery bacilli. Marked differences from this type were: (1) greater toxicity of the T. C. bacillus, assuming it to have caused death: (2) its greater sensitiveness in agglutination tests with normal sera: (3) behaviour in litmus milk.

It was found when blood serum agglutination tests with the T. C. organism were being done, that the highest end-point reached (400) was with a serum that had no connexion with the outbreak. This reaction was given in five hours. The best reaction on the part of those concerned in the outbreak was an end-point of 125 in five hours and 250 in 22 hours, given by the serum of one of the patients in the first week of illness, and an end-point of 150 in 22 hours given by a second patient in the first week of illness. The serum of this second patient reacted in a dilution of 200 on the sixteenth day and in a third test on Oct. 3rd. Though there is no significant variation in the titre of the serum in these three tests, the figures seemed notable in the presence of saline controls which were uniformly negative. But when the behaviour of the T. C. organism was observed in the presence of serum controls in addition—a series of 21 of them was used—it was seen that the above reactions were not specific. Ten of these controls gave a reaction in varying dilutions. One of them gave an end-point of 40 in three hours, and 250 in 23 hours. The seven controls which were tested in dilutions of 50 and upwards all reacted in the 50 dilution at least when given 23 hours. It followed that so long as the organism retained this sensitiveness to the action of human blood-serum, the results of agglutination tests with it and the sera of the five patients admitted to hospital gave no help.

The T. C. bacillus was not found in the fæces or urine of any of the five patients, and it was the only organism to which any degree of suspicion was attached as the result of the cultural examinations to which the lungs, spleen, blood, stomach and intestinal contents, and urine were subjected. It was found only in the intestine. The enlarged spleen was sterile. The conclusion reached at this stage of the investigation was that this organism possessed a relationship to the lactose-fermenting coliforms from its fermentative and other cultural characters, which marked it off from those of any known group of dysentery bacilli. Discussion of its serological properties and pathogenicity appears later.

Microscopical examination of the organs revealed no notable departure from the normal, with the exception of the excess of lymphoid tissue in the stomach and intestine. Examination of polony sausage and of Lorne sausage derived from the boys' hostel was made by cultural methods and by animal experiments, and did not furnish any organism which came under suspicion.

In dealing with the cases of the four boys from the hostel, admitted to Belvidere Hospital, and with the case of Mrs. J., in the Eastern District Hospital, the fæces and urine were examined and were found not to contain any organism of recognised pathogenicity. The blood-sera of the five were also subjected to exhaustive and repeated agglutination tests, but no results relating them to organisms of known pathogenicity were reached. These serum tests were done towards the end of the first week in hospital and again on August 31st. The lapse of such an interval would warrant the expectation of a positive result had the infection been due to any of the usually recognised aerobic food-poisoning organisms. As already described, these sera were also put against the T. C. organism, and a small amount of blood available from the T. C. case was put against *B. paratyphosus* B with negative result.

Two months after this outbreak, and not associated with it, a bacillus having all the biochemical characters of the T. C. bacillus was isolated in this laboratory from the fæces of a patient, R. R., who had been suffering from intestinal trouble for over a year. This bacillus R. R. was non-motile, did not form indol, nor liquefy gelatin, and fermented glucose and mannite with acid production without gas in 24 hours. Lactose and saccharose were unaffected until a date beyond the ninth and under the thirteenth day of incubation, when fermentation took place with acid production. Dulcite remained negative. After a sojourn of the organism for four days in a guinea-pig it was found that on the sixth day of incubation saccharose, and on the eighth day lactose, were fermented with acid production. Litmus milk remained acid till the eleventh day, when clotting took place. A tabular comparison of these characters shows the similarity:—

TABLE I.—*First Isolation.*

Organism.	Gluc.	Lact.	Sacch.	Dulc.	Mannite.	Motility.	Indol.	Litmus milk.	Gelatin.
I. { Bacillus T. C. ,, R. R. }	A	—	—	—	A	—	—	Slight A	—
II. { ,, T. C. ,, R. R. }	A	A	A	—	A	—	—	A.C. (11 days)	—

I. = tubes read up till 9 days' incubation.
II. = ,, ,, from 9–12 days' incubation.

Both organisms ferment maltose with production of acid in 24 hours, turning to alkalinity in about 10 days in the aerobic part of the fermentation tube, but do not ferment inosite or salicin. The two organisms are, therefore, in those respects identical. Evidence was also obtained that bacillus R. R. was identical with the T. C. bacillus serologically. A rabbit antiserum prepared with the T. C. bacillus agglutinated the homologous bacillus and bacillus R. R. to precisely the same point, a dilution of 3120, while the serum of the animal antecedently to immunisation failed to agglutinate either organism in any dilution. Bacillus R. R. as isolated from the fæces in the ordinary way, also had the character possessed by the T. C. bacillus of being sensitive to "normal" human sera. The agglutination reaction in a dilution of 200 given by the former in a test with the patient's own serum was lost after the organism had been four days under the skin of a guinea-pig. The behaviour is seen in Table II.

For the purpose in view it did not appear necessary to carry the serum controls to further dilutions, and it is clear that there were *no agglutinins in the serum* of the patient R. R. to the corresponding organism. It is clear from a view of the above facts, taken together with the fact that the bacillus R. R. absorbs all the agglutinins from an agglutinating serum of titre 3120 prepared with the T. C. organism, that these two organisms are to be regarded as identical. It was to be expected that had the bacillus R. R. been the cause of the trouble in an illness of over a year's duration, there would have been related agglutinins in the blood-serum. The absence of these was of value in removing suspicion from a bacillus which was not of the proteus type. If, then, this organism is not accepted as of pathogenic import in the case of R. R., an additional ground is furnished for rejecting what is taken to be

AN OUTBREAK OF FOOD POISONING IN GLASGOW:

A CLINICAL AND BACTERIOLOGICAL INVESTIGATION.

BY W. R. WISEMAN, M.B., B.Sc., F.R.F.P.S. GLASG.,
BACTERIOLOGICAL LABORATORIES, PUBLIC HEALTH DEPARTMENT, GLASGOW;

AND

A. S. M. MACGREGOR, O.B.E., M.D., D.P.H.,
PUBLIC HEALTH DEPARTMENT, GLASGOW.

AN outbreak of sickness of some severity, suspected to be due to food, occurred last August in a working boys' home in the east end of Glasgow. As some points of interest arose on the clinical side, and others have emerged as the result of exhaustive laboratory investigations, we think that a brief account of the outbreak is worth adding to the records of similar occurrences. For the entire bacteriological work Dr. Wiseman is responsible.

The home accommodates about 80 working lads, all of whom live in and have their meals on the premises. They are apprenticed out at various occupations throughout the city. Out of the personnel, 80 inmates and four staff, practically all of whom shared the same institutional diet, 15 of the boys and one of the maids developed more or less acute abdominal symptoms, while the remainder entirely escaped even minor disturbance. One of the lads (T. C., aged 20) died suddenly after an illness of less than 24 hours' duration, another became dangerously ill, while three others became severely ill.

General Symptoms.

Symptoms common to the majority were abdominal pain, headache, sickness with vomiting, and diarrhœa. Colic pains were complained of by all except one patient, severe frontal headache by all except three, acute enough in the severer cases to give the face a dazed expression. Vomiting, though frequent, was neither prolonged nor severe, occurred early, and was accompanied or succeeded by diarrhœa lasting from 12 to 24 hours. Excluding those earlier cases which were not observed during the acuter stages, all the others had temperatures varying from 100° to 103° F., returning to normal after the irritative symptoms had disappeared. The clinical characteristics of the outbreak were, therefore, sudden onset with brief and sharp course, symptoms of gastro-intestinal irritation, accompanied by fever with severe headache, and followed by rapid convalescence.

An Illustrative Case.

M. McA., aged 19. This lad took ill about 11 P.M. on August 14th, with abdominal pain, headache, vomiting, and diarrhœa, all of which became very severe during the night. On the morning of the 15th his condition was serious, with great prostration, lividity of face, cramps in the limbs, somnolence, heavily furred tongue, pain and tenderness in the upper region of the abdomen, temperature 102° F., with a dry skin. He was admitted to hospital in the early afternoon, where he vomited a quantity of bright jade green material, the stools being loose, small, and green. Towards evening he became dangerously ill, with feeble pulse and deepening cyanosis. Diarrhœa continued infrequently next day, vomiting occurred once, and his general condition improved. By the following day, the 17th, the irritative symptoms had ceased and the patient was out of danger.

The chart shows the progress of the pulse and temperature. Three of the severer cases who were admitted to hospital for treatment show the same continued fall in the pulse after the temperature had rapidly subsided to normal.

The fatal case (T. C., aged 20) first complained of sickness, vomiting, and thirst on the evening of August 14th, although it appears that he had not been well at his work during the day. He had diarrhœa during the night, and, when the bed-clothes were about to be changed at 7 A.M., he suddenly collapsed and died. The results of the post-mortem and of the bacteriological examination are given later.

The maid, who was the only one of the staff to sicken, took ill on the night of August 13th and was admitted to hospital next day, sharply ill with vomiting, diarrhœa, and temperature 101° F. The stools consisted of blood and mucus; this was the only case in which blood was noticed in the fæces.

Source of the Illness.

As nearly as could be ascertained the periods of sickening of the 16 cases were as follows: morning of August 13th, five cases; evening of same day, one case; morning of 14th, five cases; evening of same day, five cases. The one fatal case and the more severe cases belong to this last group.

The articles of food consumed by all the inmates on August 12th and 13th were investigated, and that upon which most suspicion rested was the meat partaken of on both these dates. The dinner of Sunday, the 12th, had been prepared on the previous afternoon, and consisted of Argentine boneless meat, which had been boiled, removed from the pot, and served cold next day. The water left in the pot, a large iron one, had been used to boil dried green peas. On Monday, the 13th, the remainder of the meat was served for lunch, most of the boys taking sandwiches to their work. The evening dinner on the 13th consisted of Lorne sausage and potatoes, along with the remainder of the peas and gravy left over from Sunday's dinner. Unfortunately, none of the food, with the exception of one or two pieces of uncooked sausage, was available for examination. No specimen of the meat could be got either from the home or the shop from which it had been obtained. As far as the dates of sickening and consumption of food are concerned, the source may have been either the meat or the water in which it was boiled. As only 16 of the 84 inmates were affected, this selective incidence is more suggestive of a source in the meat itself than in the gravy.

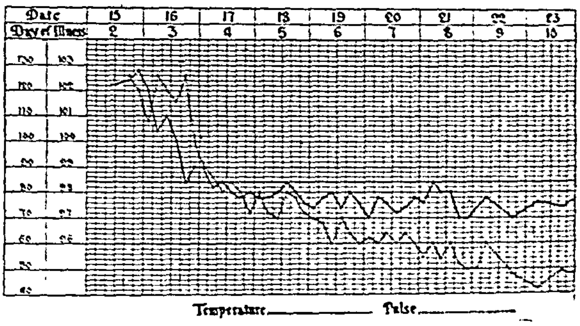

Chart showing progress of the temperature and pulse.

Post-mortem Examination of the Fatal Case (T. C.).

Dr. R. M. Buchanan, who performed the post-mortem examination, was of opinion that the conditions indicated gastro-enteritis. The points of main importance were the swollen mucous membrane of the stomach with—

> "a large irregular area marked by ecchymoses but no obvious ulceration over the greater curvature. . . . Over the lower part of the ileum there is a faint suffused redness. . . . The mucous membrane of the large intestine exhibits an intense uniform redness in its whole extent. Its contents are scanty, of creamy consistence, greyish yellow, and very slightly tinted with blood."

Bacteriological Examination.

From the rectum of the patient who died a bacillus was isolated in almost pure culture which failed to ferment lactose in one day. Examination of the fermentation reactions of this organism appeared at first to relate it to the Flexner group of dysentery bacilli. After 7–9 days' incubation, however, it was found that the organism fermented lactose with acid production, and in 11 days produced acid and clot in litmus milk. On Oct. 15th, 1923, the original culture and a subculture twice removed from the original were re-tested. Both cultures produced acid fermentation in lactose and saccharose on prolonged incubation, and both produced acid and clot in litmus milk in 11 days. The subculture was more rapid in its action on saccharose than the original culture. The milk control tubes (*a*) uninoculated, (*b*) inoculated with *B. Flexner* V, showed no visible change in 12 days. The organism was non-motile and was negative for production of indol. It was noted that after 24–28 days the lactose and saccharose fluid media tended to become alkaline. Animal experiments will be detailed later.

The reactions just described place the bacillus in question outside the Flexner group of dysentery bacilli, apart from the fact that it gave negative results in agglutination tests with *B. Flexner* V, W, X, Y (Oxford), and Z. Excepting the reaction in litmus milk, this T. C. bacillus resembles in "sugar" fermentations, non-motility, and negative indol formation the Sonne III. type of dysentery bacilli. Marked differences from this type were: (1) greater toxicity of the T. C. bacillus, assuming it to have caused death; (2) its greater sensitiveness in agglutination tests with normal sera; (3) behaviour in litmus milk.

It was found when blood serum agglutination tests with the T. C. organism were being done, that the highest end-point reached (400) was with a serum that had no connexion with the outbreak. This reaction was given in five hours. The best reaction on the part of those concerned in the outbreak was an end-point of 125 in five hours and 250 in 22 hours, given by the serum of one of the patients in the first week of illness, and an end-point of 150 in 22 hours given by a second patient in the first week of illness. The serum of this second patient reacted in a dilution of 200 on the sixteenth day and in a third test on Oct. 3rd. Though there is no significant variation in the titre of the serum in these three tests, the figures seemed notable in the presence of saline controls which were uniformly negative. But when the behaviour of the T. C. organism was observed in the presence of serum controls in addition—a series of 21 of them was used—it was seen that the above reactions were not specific. Ten of these controls gave a reaction in varying dilutions. One of them gave an end-point of 40 in three hours, and 250 in 23 hours. The seven controls which were tested in dilutions of 50 and upwards all reacted in the 50 dilution at least when given 23 hours. It followed that so long as the organism retained this sensitiveness to the action of human blood-serum, the results of agglutination tests with it and the sera of the five patients admitted to hospital gave no help.

The T. C. bacillus was not found in the fæces or urine of any of the five patients, and it was the only organism to which any degree of suspicion was attached as the result of the cultural examinations to which the lungs, spleen, blood, stomach and intestinal contents, and urine were subjected. It was found only in the intestine. The enlarged spleen was sterile. The conclusion reached at this stage of the investigation was that this organism possessed a relationship to the lactose-fermenting coliforms from its fermentative and other cultural characters, which marked it off from those of any known group of dysentery bacilli. Discussion of its serological properties and pathogenicity appears later.

AN OUTBREAK OF FOOD POISONING IN GLASGOW:

A CLINICAL AND BACTERIOLOGICAL INVESTIGATION.

BY W. R. WISEMAN, M.B., B.Sc., F.R.F.P.S. GLASG.,
BACTERIOLOGICAL LABORATORIES, PUBLIC HEALTH DEPARTMENT, GLASGOW;
AND
A. S. M. MACGREGOR, O.B.E., M.D., D.P.H.,
PUBLIC HEALTH DEPARTMENT, GLASGOW.

AN outbreak of sickness of some severity, suspected to be due to food, occurred last August in a working boys' home in the east end of Glasgow. As some points of interest arose on the clinical side, and others have emerged as the result of exhaustive laboratory investigations, we think that a brief account of the outbreak is worth adding to the records of similar occurrences. For the entire bacteriological work Dr. Wiseman is responsible.

The home accommodates about 80 working lads, all of whom live in and have their meals on the premises. They are apprenticed out at various occupations throughout the city. Out of the personnel, 80 inmates and four staff, practically all of whom shared the same institutional diet, 15 of the boys and one of the maids developed more or less acute abdominal symptoms, while the remainder entirely escaped even minor disturbance. One of the lads (T. C., aged 20) died suddenly after an illness of less than 24 hours' duration, another became dangerously ill, while three others became severely ill.

General Symptoms.

Symptoms common to the majority were abdominal pain, headache, sickness with vomiting, and diarrhœa. Colic pains were complained of by all except one patient, severe frontal headache by all except three, acute enough in the severer cases to give the face a dazed expression. Vomiting, though frequent, was neither prolonged nor severe, occurred early, and was accompanied or succeeded by diarrhœa lasting from 12 to 24 hours. Excluding those earlier cases which were not observed during the acuter stages, all the others had temperatures varying from 100° to 103° F., returning to normal after the irritative symptoms had disappeared. The clinical characteristics of the outbreak were, therefore, sudden onset with brief and sharp course, symptoms of gastro-intestinal irritation, accompanied by fever with severe headache, and followed by rapid convalescence.

An Illustrative Case.

M. McA., aged 19. This lad took ill about 11 P.M. on August 14th, with abdominal pain, headache, vomiting, and diarrhœa, all of which became very severe during the night. On the morning of the 15th his condition was serious, with great prostration, lividity of face, cramps in the limbs, somnolence, heavily furred tongue, pain and tenderness in the upper region of the abdomen, temperature 102° F., with a dry skin. He was admitted to hospital in the early afternoon, where he vomited a quantity of bright jade green material, the stools being loose, small, and green. Towards evening he became dangerously ill, with feeble pulse and deepening cyanosis. Diarrhœa continued infrequently next day, vomiting occurred once, and his general condition improved. By the following day, the 17th, the irritative symptoms had ceased and the patient was out of danger.

The chart shows the progress of the pulse and temperature. Three of the severer cases who were admitted to hospital for treatment show the same continued fall in the pulse after the temperature had rapidly subsided to normal.

The fatal case (T. C., aged 20) first complained of sickness, vomiting, and thirst on the evening of August 14th, although it appears that he had not been well at his work during the day. He had diarrhœa during the night, and, when the bed-clothes were about to be changed at 7 A.M., he suddenly collapsed and died. The results of the post-mortem and of the bacteriological examination are given later.

The maid, who was the only one of the staff to sicken, took ill on the night of August 13th and was admitted to hospital next day, sharply ill with vomiting, diarrhœa, and temperature 101° F. The stools consisted of blood and mucus; this was the only case in which blood was noticed in the fæces.

Source of the Illness.

As nearly as could be ascertained the periods of sickening of the 16 cases were as follows: morning of August 13th, five cases; evening of same day, one case; morning of 14th, five cases; evening of same day, five cases. The one fatal case and the more severe cases belong to this last group.

The articles of food consumed by all the inmates on August 12th and 13th were investigated, and that upon which most suspicion rested was the meat partaken of on both these dates. The dinner of Sunday, the 12th, had been prepared on the previous afternoon, and consisted of Argentine boneless meat, which had been boiled, removed from the pot, and served cold next day. The water left in the pot, a large iron one, had been used to boil dried green peas. On Monday, the 13th, the remainder of the meat was served for lunch, most of the boys taking sandwiches to their work. The evening dinner on the 13th consisted of Lorne sausage and potatoes, along with the remainder of the peas and gravy left over from Sunday's dinner. Unfortunately, none of the food, with the exception of one or two pieces of uncooked sausage, was available for examination. No specimen of the meat could be got either from the home or the shop from which it had been obtained. As far as the dates of sickening and consumption of food are concerned, the source may have been either the meat or the water in which it was boiled. As only 16 of the 84 inmates were affected, this selective incidence is more suggestive of a source in the meat itself than in the gravy.

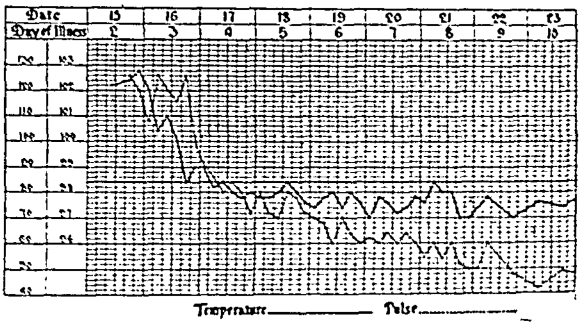

Chart showing progress of the temperature and pulse.

Post-mortem Examination of the Fatal Case (T. C.).

Dr. R. M. Buchanan, who performed the post-mortem examination, was of opinion that the conditions indicated gastro-enteritis. The points of main importance were the swollen mucous membrane of the stomach with—

> "a large irregular area marked by ecchymoses but no obvious ulceration over the greater curvature. . . . Over the lower part of the ileum there is a faint suffused redness. . . . The mucous membrane of the large intestine exhibits an intense uniform redness in its whole extent. Its contents are scanty, of creamy consistence, greyish yellow, and very slightly tinted with blood."

Bacteriological Examination.

From the rectum of the patient who died a bacillus was isolated in almost pure culture which failed to ferment lactose in one day. Examination of the fermentation reactions of this organism appeared at first to relate it to the Flexner group of dysentery bacilli. After 7–9 days' incubation, however, it was found that the organism fermented lactose with acid production, and in 11 days produced acid and clot in litmus milk. On Oct. 15th, 1923, the original culture and a subculture twice removed from the original were re-tested. Both cultures produced acid fermentation in lactose and saccharose on prolonged incubation, and both produced acid and clot in litmus milk in 11 days. The subculture was more rapid in its action on saccharose than the original culture. The milk control tubes (*a*) uninoculated, (*b*) inoculated with *B. Flexner* V, showed no visible change in 12 days. The organism was non-motile and was negative for production of indol. It was noted that after 24–28 days the lactose and saccharose fluid media tended to become alkaline. Animal experiments will be detailed later.

The reactions just described place the bacillus in question outside the Flexner group of dysentery bacilli, apart from the fact that it gave negative results in agglutination tests with *B. Flexner* V, W, X, Y (Oxford), and Z. Excepting the reaction in litmus milk, this T. C. bacillus resembles in "sugar" fermentations, non-motility, and negative indol formation the Sonne III. type of dysentery bacilli. Marked differences from this type were: (1) greater toxicity of the T. C. bacillus, assuming it to have caused death; (2) its greater sensitiveness in agglutination tests with normal sera; (3) behaviour in litmus milk.

It was found when blood serum agglutination tests with the T. C. organism were being done, that the highest end-point reached (400) was with a serum that had no connexion with the outbreak. This reaction was given in five hours. The best reaction on the part of those concerned in the outbreak was an end-point of 125 in five hours and 250 in 22 hours, given by the serum of one of the patients in the first week of illness, and an end-point of 150 in 22 hours given by a second patient in the first week of illness. The serum of this second patient reacted in a dilution of 200 on the sixteenth day and in a third test on Oct. 3rd. Though there is no significant variation in the titre of the serum in these three tests, the figures seemed notable in the presence of saline controls which were uniformly negative. But when the behaviour of the T. C. organism was observed in the presence of serum controls in addition—a series of 21 of them was used—it was seen that the above reactions were not specific. Ten of these controls gave a reaction in varying dilutions. One of them gave an end-point of 40 in three hours, and 250 in 23 hours. The seven controls which were tested in dilutions of 50 and upwards all reacted in the 50 dilution at least when given 23 hours. It followed that so long as the organism retained this sensitiveness to the action of human blood-serum, the results of agglutination tests with it and the sera of the five patients admitted to hospital gave no help.

The T. C. bacillus was not found in the fæces or urine of any of the five patients, and it was the only organism to which any degree of suspicion was attached as the result of the cultural examinations to which the lungs, spleen, blood, stomach and intestinal contents, and urine were subjected. It was found only in the intestine. The enlarged spleen was sterile. The conclusion reached at this stage of the investigation was that this organism possessed a relationship to the lactose-fermenting coliforms from its fermentative and other cultural characters, which marked it off from those of any known group of dysentery bacilli. Discussion of its serological properties and pathogenicity appears later.

Microscopical examination of the organs revealed no notable departure from the normal, with the exception of the excess of lymphoid tissue in the stomach and intestine. Examination of polony sausage and of Lorne sausage derived from the boys' hostel was made by cultural methods and by animal experiments, and did not furnish any organism which came under suspicion.

In dealing with the cases of the four boys from the hostel, admitted to Belvidere Hospital, and with the case of Mrs. J., in the Eastern District Hospital, the fæces and urine were examined and were found not to contain any organism of recognised pathogenicity. The blood-sera of the five were also subjected to exhaustive and repeated agglutination tests, but no results relating them to organisms of known pathogenicity were reached. These serum tests were done towards the end of the first week in hospital and again on August 31st. The lapse of such an interval would warrant the expectation of a positive result had the infection been due to any of the usually recognised aerobic food-poisoning organisms. As already described, these sera were also put against the T. C. organism, and a small amount of blood available from the T. C. case was put against *B. paratyphosus* B with negative result.

Two months after this outbreak, and not associated with it, a bacillus having all the biochemical characters of the T. C. bacillus was isolated in this laboratory from the fæces of a patient, R. R., who had been suffering from intestinal trouble for over a year. This bacillus R. R. was non-motile, did not form indol, nor liquefy gelatin, and fermented glucose and mannite with acid production without gas in 24 hours. Lactose and saccharose were unaffected until a date beyond the ninth and under the thirteenth day of incubation, when fermentation took place with acid production. Dulcite remained negative. After a sojourn of the organism for four days in a guinea-pig it was found that on the sixth day of incubation saccharose, and on the eighth day lactose, were fermented with acid production. Litmus milk remained acid till the eleventh day, when clotting took place. A tabular comparison of these characters shows the similarity:—

TABLE I.—*First Isolation.*

	Organism.	Gluc.	Lact.	Sacch.	Dulc.	Mannite.	Motility.	Indol.	Litmus milk.	Gelatin.
I.	Bacillus T. C. ,, R. R.	A	—	—	—	A	—	—	Slight A	—
II.	,, T. C. ,, R. R.	A	A	A	—	A	—	—	A.C. (11 days)	—

I. = tubes read up till 9 days' incubation.
II. = ,, ,, from 9–12 days' incubation.

Both organisms ferment maltose with production of acid in 24 hours, turning to alkalinity in about 10 days in the aerobic part of the fermentation tube, but do not ferment inosite or salicin. The two organisms are, therefore, in those respects identical. Evidence was also obtained that bacillus R. R. was identical with the T. C. bacillus serologically. A rabbit antiserum prepared with the T. C. bacillus agglutinated the homologous bacillus and bacillus R. R. to precisely the same point, a dilution of 3120, while the serum of the animal antecedently to immunisation failed to agglutinate either organism in any dilution. Bacillus R. R. as isolated from the fæces in the ordinary way, also had the character possessed by the T. C. bacillus of being sensitive to "normal" human sera. The agglutination reaction in a dilution of 200 given by the former in a test with the patient's own serum was lost after the organism had been four days under the skin of a guinea-pig. The behaviour is seen in Table II.

For the purpose in view it did not appear necessary to carry the serum controls to further dilutions, and it is clear that there were no agglutinins in the serum of the patient R. R. to the corresponding organism. It is clear from a view of the above facts, taken together with the fact that the bacillus R. R. absorbs all the agglutinins from an agglutinating serum of titre 3120 prepared with the T. C. organism, that these two organisms are to be regarded as identical. It was to be expected that had the bacillus R. R. been the cause of the trouble in an illness of over a year's duration, there would have been related agglutinins in the blood-serum. The absence of these was of value in removing suspicion from a bacillus which was not of the proteus type. If, then, this organism is not accepted as of pathogenic import in the case of R. R., an additional ground is furnished for rejecting what is taken to be the same organism as having pathogenic significance in the T. C. case. Nor does it appear likely that R. R. had been a carrier of that organism during the preceding 12 months, for it was found on only one occasion out of several examinations of the fæces. This case had been the subject of examination in different laboratories throughout the country, but no organism came under suspicion. *B. proteus vulgaris* was isolated in this laboratory at a time when recovery was becoming marked, and it is not known what part it may have played earlier in the case. This strain of *B. proteus vulgaris* is, however, agglutinated to titre (8000) by a serum prepared with another strain of *B. proteus vulgaris* which is known to one of us to have been definitely pathogenic in man.

TABLE II.—*Agglutinations.*

Organism.	Patient "R. R.'s" serum dilution.				Hours.
	25	50	100	200	
Bac. "R. R." (1st plate isolation).	+ +	+ +	+	+	22

	Ser. 85.		Ser. 32.		
Bac. T. C. ..	+ + +	+ + +	+	—	

Saline controls were always negative.

On August 9th, almost concurrently with this outbreak, a lactose-fermenting coliform bacillus, *B. communior* (MacConkey, 1905), was isolated by one of us from the blood of an adult patient, Mrs. F., whose symptoms very much resembled those of enteric fever, who resided not far from the boys' hostel, but was not associated with the outbreak. The same organism was isolated from a second hæmoculture of this patient on the 15th, and a bacillus culturally identical with it was present in the fæces and urine. Her blood-serum on the latter date had an agglutination titre of 2500 against this organism, serum and saline controls giving no reaction. This occurrence supported the desire to make a complete survey of the reputedly non-pathogenic coliform bacilli found in the fæces of the five patients of the boys' hostel and in the alimentary tract of the boy who died. The only organism of this kind common to the majority of the sufferers—it was found in five out of six, and was present in the stomach contents of T. C.—was *B. communior*. On the assumption that it might have taken on a pathogenic character in some foodstuff that had escaped collection and examination, it was thought expedient to ascertain if the patient's sera in our possession would throw light on this possibility. Two sets of sera were available, one set of five taken towards the end of the first week of illness, and one of four taken on the sixteenth day. Agglutination tests were done with all these sera and the *B. communior* of the five patients. If this organism were the causal agent, it was clear that the five cultures, or the majority of them, would be homologous and would give the same reactions with any one serum. It became obvious that they did not do so. In only one test out of 25, with the first set of sera, was a reaction given in a dilution of 50, five reacted in a 25 dilution, and in 10 of the tests (five of which pertained to one organism) no reaction was given. The saline controls were always negative, while of 22 serum controls used one gave a reaction in a 200 dilution with the *B. communior* of T. C. It was noted also that it was not a feature of the results that a given patient's serum gave a better raction with his own organism than with one or more of the others. When it was seen in the tests with the second set of patient's sera that there was practically no variation in the titres between August 22nd and 31st, the conclusion was reached that we were not dealing here with an ætiological factor. The immune sera of three rabbits prepared by inoculation with two of these organisms and with that of Mrs. F. (hæmoculture) showed definitely that these three bacilli were heterologous.

It would seem to follow from this that the moderate reactions just described are not on a par with those given by certain "normal" sera with *B. enteritidis* Gaertner—e.g., in a series of 50 normal sera tested in this laboratory against *B. enteritidis* Gaertner 10 gave good reactions in a dilution of 85; of these 10, five reacted in a 125 dilution and two reacted well in a 250 dilution. The absorption tests done on these last two, and on one of the five, showed complete absorptions. The serological specificity of *B. enteritidis* Gaertner renders it likely that these results indicate a specific relation between this bacillus and the sera. On the other hand, similar reactions with different strains of *B. communior*, freshly isolated and proved heterologous, evidently mean some degree of sensitiveness to the action of certain human sera simply as such.

The search for anaerobic bacilli in this investigation did not produce any indication that any solution was to be found along this line.

The Ætiological Factor a Toxin.

In dealing with all the living micro-organisms that could by any possibility have caused this outbreak, we have wished to place upon a sound basis of fact our conviction that it was due to the ingestion of a toxin. It remains obscure what the nature of the toxin was, much yet remaining to be done to place the isolation of such bodies from foodstuffs and their description upon a satisfactory basis.

Animal Experiments to Ascertain Pathogenicity.

The following animal experiments were carried out to ascertain pathogenicity:—

(*a*) Half of the washings of 3 grammes of polony sausage and of Lorne sausage, which were derived from the home, were injected subcutaneously into guinea-pigs. The animals remained well.

(*b*) 0·1 c.cm. of a 24 hours' broth culture of the organism referred to as the T. C. bacillus (found in the rectum post mortem) was given subcutaneously to a guinea-pig on Sept. 5th. The animal remained well. On Nov. 21st a guinea-pig received intraperitoneally 2 c.cm. of the filtrate of a five days' broth culture of this organism and remained well. On April 10th, 1924, a guinea-pig was given subcutaneously 0·5 c.cm. of an 18 hours' broth culture, while another received 0·5 c.cm. of the same culture intraperitoneally. Both animals remained well.

(*c*) To be correlated with (*b*) are the experiments with the identical bacillus R. R. A guinea-pig received a subcutaneous inoculation of a saline emulsion of the fæces of the patient R. R. and was killed in four days. There was a dense fibrinous exudation at the site of inoculation and the late lactose-fermenting bacillus was found here by culture without difficulty. It was not found in the contents of the large or the small intestine. Blood culture was negative.

A feeding experiment was done with the same saline emulsion as used for the inoculation with no discernible pathogenic effect.

Experiment with Pure Culture of Bacillus R. R.—On Nov. 29th, 1923, 11 days after the first isolation of the organism, a guinea-pig received subcutaneously 0·5 c.cm. of a 24 hours' broth culture (from fourth subculture on agar). On Dec. 7th there was an indurated swelling 1½ inches by 1 inch at the site of inoculation. On the 11th the swelling was somewhat less in area, 2 inches by ½ an inch, and apparently very tender. The animal was otherwise well, and ultimately recovered.

(*d*) The *B. communior* from the stomach of T. C. and that from one of the patients, H., were tested by subcutaneous inoculation of broth cultures in guinea-pigs with negative results. The former was also grown for five days in bouillon and a guinea-pig fed with 2 c.cm. of the filtrate, while another guinea-pig received 1 c.cm. of the filtrate intraperitoneally. Both experiments gave negative results.

Conclusions.

1. It is held that, even in the absence of access to a sample of the meat upon which suspicion mainly fell, the investigations described have been sufficiently comprehensive to exclude the direct action of a living micro-organism, apart from a filtrable virus, as the cause of the outbreak.
2. Before direct microbial action could be excluded, a detailed investigation was made upon an organism of rare occurrence in the human intestine, which organism was found in the fatal case and also in a case of intestinal trouble not associated with the outbreak. Grounds are given for regarding the outbreak as not attributable to this organism.
3. The bacilli described as T. C. and R. R. appear to be members of a serological group which is either a new group or one of very uncommon occurrence. Further, the bacillus R. R. was found to be moderately pathogenic to guinea-pigs.
4. The clinical data (including the selective incidence) combined with the bacteriological results furnish strong grounds for the view that the outbreak was due to a powerful toxin which had an uneven distribution in the material consumed.

AN INQUIRY INTO THE ORIGIN OF SQUINT, LEFT-HANDEDNESS AND STAMMER.

BY W. S. INMAN, M.B. LOND.,
SENIOR OPHTHALMIC SURGEON, PORTSMOUTH AND SOUTH HANTS EYE AND EAR HOSPITAL.

THE nature and origin of concomitant squint have been explained in physiological terms, but its capricious incidence indicates that further factors must be involved beyond the known physiological ones. Its mode of onset and variability in states of fear or other excitement suggest that, whatever may be the influence of an error of refraction, some other factor must be at work determining the breakdown of the binocular function; but the difficulties of direct investigation of the child's mind appeared insurmountable, and for some time after my attention was drawn to such a possibility I had to content myself with observations confirming the suspicion that the deformity was dependent upon mental states. Soon it was noticed that several squinting patients were left-handed, and further investigation elicited the fact that even when not left-handed themselves a large proportion of the children had left-handed relatives. From this point it was natural to turn to the incidence of stammering, which for many years has been considered a congener of left-handedness, and I discovered that a family history of stammering could often be obtained. Why should a habit which represented a harmless departure from the custom of the herd, carrying with it no generally recognised physical or mental disability, be associated with serious defects of sight and speech? Whatever may be the explanation, the question suggests new paths by which to investigate the origin of squint, if the association of the abnormalities can be established.

I have been able to collect 1000 cases of squint, very few of which have failed to reveal the existence of left-handedness or stammering in some near relative, and it is hoped that the typical instances quoted will be of sufficient significance to justify the absence of statistical proof of the association. Seeking a physical explanation of the relationship seemed like the proverbial search for a needle in a haystack. Stammering has long been recognised to be a "nervous" symptom, and squint is commonly seen to vary with the emotional reactions of the child, so it appeared that research into the relationship of mental states with all three conditions would be more profitable than inquiry into possible structural peculiarities.

Left-handedness.

Though left-handedness has never yet been classified among diseases, yet a most striking feature is the intolerance shown towards it. But this attitude is directed only towards children. Once the individual has been able to weather the storm of disapproval from parents and teachers, he is left alone, and may even be commended if the left-handedness be applied to games. In cricket, especially, we like a left-handed bowler or batsman on our side, for he has a sphere of usefulness which no one else can fill. Superficially regarded, the left-hander is as other men. Often, however, he *is* different from his fellows in certain subtle ways, and the difference seems to be connected with the difficulty experienced in childhood in establishing his right to do as he pleases. Whether he was born with a capacity for complete ambidexterity, and clings to such left-handed activities as have survived parental pressure, or whether he has actually adopted left-handedness as a sign of his desire to be different from the authoritative parent, the fact remains that he is almost invariably more critical and self-sufficient than the other members of the family.

The reason for the normal habit of right-handedness is unknown, and a considerable proportion of children show an inclination to use either hand in their earliest activities. As a rule, perhaps from training or example, the right hand soon becomes dominant, and a habit is formed which remains through life, though sometimes there seems to be a reservation in the individual's mind, for I have patients who assert that notwithstanding their right-handedness, they "feel" left-handed. Such a case, a right-handed woman of 28, came under my notice last year. It was found that the girth of the left arm was three-quarters of an inch larger than the right. Further, the measurement across the left breast was larger than that of the right by the same amount. There was nothing in the medical history to account for this difference, or for the "feeling" of left-handedness. Another right-handed patient, a woman of 25, told me that it was "the greatest ambition of her life to be left-handed."

Development of the Condition.—So far as I know, few investigations have yet been made into the earliest manifestations of left-handedness, such records as exist being merely incidental to other aims. An instance of late emergence of left-handedness came to my notice recently.

A naval officer had occasion for the first time to chastise his little girl of 4, for naughtiness. Later in the day, when good relations appeared to have been re-established, she was invited to play a game invented in the family. Over the perforated seat of a chair was stretched a piece of paper, and the players tried to pierce the paper over one of the holes with a lead pencil. The father tried first, and then passed the pencil to his daughter, who took it and struck with it in her left hand. When she did this a second time, the father commented upon it, and tried to persuade her to use the right hand in place of the left, but without success. This was the first occasion on which any sign of left-handedness had been given. In this family the father has a tendency to divergent squint, the mother's only brother has a pronounced convergent squint, in one or two of the other children there is a suggestion of divergent squint, and the mother, though not left-handed, uses mirror writing in making private notes.

A more significant case seems to be that of a boy of 7, who had squinted since the age of 2. He was right-handed until he was 6, when he became very friendly with a left-handed boy, and began to copy him, even to the extent of learning to write with the left hand. The habit was "broken" by the parents. No other squint, stammer, or left-handedness could be traced in the family.

A curious feature about left-handedness is that it is rarely as complete as right-handedness. We are familiar with the man who bats left-handedly, and bowls with the right hand, or vice versa. One of my patients is left-handed only for two-handed activities, such as swinging a golf club or cricket bat. Another uses a pen with the right hand and a pencil with the left. Yet another sharpens a pencil with the left hand, but at table holds knife and fork normally. A fourth invariably blows his nose with his handkerchief in the left hand. There may be one or many left-handed activities in people who are regarded by their fellows as normally right-handed.

Whatever may be the cause of this departure from the usual custom, there seems in most cases to be no reason for attributing it to physical conditions.

Emotion as a Causal Factor—I have found only one case where a left-handed parent did not object strongly to his child following his example. One man had resorted to the extreme measure of training himself to be right-handed, in order to influence his left-handed son, when coercive measures had failed. He declared that it was only a matter of "will-power." It is strange that no left-hander feels that this blame is merited; he, at least, is never ashamed of his habit. A little patient of mine was said to have become left-handed in order to please a favourite left-handed uncle. It would be interesting to know why she did not remain right-handed in order to please her right-handed father. These examples suggest an emotional factor in the development of left-handedness.

Incidence of Left-handedness.

The problem becomes more complex when we find that boys are more likely to be affected than girls. J. W. W. Ballin, in his annual report, Board of Education, St. Louis, 1915–16, found amongst nearly 90,000 pupils that the percentage of the left-handers in boys was 3·6, and amongst the girls 2·1. Mental defectives, too, include a high proportion of left-handers, and so do twins. I am under the impression that the elder twin is more likely to be left-handed, and that in large families the eldest child, especially if a boy, is more commonly affected. In the case of mental defectives it might be imagined that structural brain formation had determined the issue as to which hand should be used, but that a functional element is present is indicated by Hugh Gordon,[1] who states that "spontaneous change of left-handedness to right-handedness in writing amongst mental defectives is often found to be associated with progress in school work and in intelligence." Lombroso found a high percentage of left-handers amongst criminals. Is there a common factor present in these various classes which tend to develop the abnormality? The mental defective has a definite inferiority in comparison with his fellows, and a feeling of resentment may perhaps be attributed to him; as this inferiority passes away, he tends to conform to the usual custom. The criminal is in conflict with the herd. The boy is more aggressive and independent than the girl. The common factor which seems to emerge is a spirit of contrariness. As already stated, the attribute of left-handedness in the adult does not carry with it any imputation of blameworthiness; other things being equal, he is assumed to be as useful a member of society as the right-hander. Does he then show any sign of the spirit of contrariness? My observations point to the conclusion that in many cases the left-hander has his own peculiar temperament.

A mental expert, corresponding with me on this subject, wrote: "I have a patient who is extremely left-handed, and his past history relates terrible conflicts with his father. In fact he is the most left-handed man I have ever known, except myself! I, too, have experienced much conflict with father substitutes—e.g., commanding officers, Government officials, &c." A still more striking example of obstructiveness is that of a man, the only left-hander of his family, whose opposition to authority of any kind was so great that he relinquished post after post abroad and at home, when it appeared that he was settled for life, because some higher official ventured to control his actions. This resentful attitude towards authority can be found in most left-handers. It may be urged that mankind naturally tends to resist authority, but if the left-hander be compared with the rest of his family, brought up by the same parents, it will be found that he is generally distinguished by being to a greater degree than his fellows self-reliant, critical and obstinate, refusing to be driven, but accepting guidance from those he loves.

Relationship of Left-handedness and Stammering.

The relationship of left-handedness and stammering has been shown by the onset of the latter where forcible restraint of left-handedness has been practised. On the other hand, stammering appears sometimes to have resulted from an attempt to make a right-hander ambidextrous. An elderly father of strong personality, who is keenly interested in manual dexterity, had a right-handed daughter, whom he taught to use the left hand without much difficulty or undesirable sequelæ. An attempt to educate in the same way a son who was born two or three years later had to be abandoned owing to the development of a stammer.

Whether parental pressure had any influence in determining the incidence of left-handedness on the female side only in the following family history I was unable to ascertain.

A girl of 8 was brought to me suffering from a blinking habit. She was left-handed even for writing. She was the youngest of the family, which consisted of two sisters, the elder of whom was slightly left-handed, and one brother, who had an internal squint. The mother was left-handed for most activities; so was her only sister, but her only brother, who died at the age of 16, was normal. The mother's mother also was left-handed. There had never been any stammer in the family. Thus, for three generations left-handedness was present in the females only.

Hugh Gordon[2] published in 1920 the result of an experiment at Lingfield Colony Special Schools (Epileptic Children) upon certain "stationary" children, who seemed to have developed up to a certain point and then stuck. It had been thought that left-side training might open up additional centres in the brain, and enable education to proceed in these children, who had been stationary for two to four years. A class was formed and some progress was made, when, about five months from the commencement of the experiment, it was found that the pupils, beginning with those who were making the best and most regular advance under the "left" method, began to speak in halting phrase, and gradually developed a pronounced stammer. The speech had previously been normal. A singular fact was that so long as the movements of the left hand were purely mirror-writing movements—which was the procedure adopted at the beginning of the training—there was no interference with speech. The stammer appeared only when the left hand was made to perform movements in the same direction as those normally performed by the right. This progressive speech defect became so alarming that it was decided to abandon the left-side work in favour of ambidexterity. By the time that both hands had begun to acquire steadiness and skill, an improvement in speech was noticed, and after some weeks the defect had entirely disappeared.

On the other hand, I have known of only one case where a left-hander developed a squint when an attempt was made to enforce right-handedness.

---

[1] Brain, vol. xliii., Part iv., 1920.

[2] The Times Educational Supplement, May 6th, 1920.

A boy of 7 or 8 was sent to a school where the master insisted upon his becoming right-handed. The boy found difficulty in compliance, was beaten, and at each beating developed a temporary squint. An example of the variation of squint and stammering cannot be given, though I have seen a boy who stammered more when he read the letters on the test type with the squinting amblyopic eye than he did when the other eye was used. Another boy developed a squint of the left eye after an injury when 4 years old, and a month later began to stammer. A strange case is that of a woman of 38, who, in the late months of pregnancy, awoke one morning with a paralytic internal squint of the left eye. In her alarm she called her eldest daughter, aged 19, to come and see what was wrong, and the latter, as soon as she saw the deformity, immediately began to stammer, and continued to do so for many months.

Whilst it is usual for these three abnormalities to occur singly in the various members of the family, two or all of them may be, or may have been, present in the same individual, though all may not persist. Thus it is fairly common to hear that a squinter used to be a stammerer or left-hander in childhood, without any trace being present when he grew up. An instance has been given where the left-handedness occurred only on the female side of the family. Squint, too, may be confined to one sex, as in the family of a patient aged 19, whose squint developed after going to school. He had three sisters, aged 16, 24, and 30 respectively, who were normal, whilst of three brothers, one, a squinter, died of consumption at the age of 27; a second, aged 32, also squinted; and the other, aged 12, was normal. The father and father's brother both squinted.

The Emotional Factor in Stammering and Squinting.

It is perhaps hardly necessary to say much about the emotional origin of stammering, which is commonly recognised to be a nervous symptom, but it may be interesting to notice that just as left-handedness can be partial, and squint intermittent, so can stammer be confined to specific occasions. Some stammerers are affected only in the presence of superiors, some fail at certain letters, and the experience of war cases showed that a stammer was often initiated by a single emotional experience. A sufficient number of cases have now been analysed to demonstrate the effect of emotion in starting and perpetuating the disorder of speech.

In the course of observation of squinting children I have been able to find abundant evidence that emotion may determine both the incidence and extent of the deviation. Excitement often plays a prominent part, and the following instance illustrates how fundamental may be the stresses, how early they may arise, and their value as an indication that the child's mental development is not proceeding smoothly.

A little girl of 2 years and 4 months was brought to me in July last with a left internal squint. The mother could not account for the squint, but a habit of standing on her head recently indulged in a good deal by the child, had been suggested as a cause. She was right-handed, and the speech was normal. In October the mother reported that the child had begun to stammer during the past two or three weeks, and also during the same period had become left-handed for putting food into her mouth, or for picking up anything. She used the left hand for most purposes more than the right. When asked if the emotional atmosphere at home had changed lately, the mother replied that she and her husband had not been happy together for some months, and that in the past two or three weeks they had been discussing the advisability of a legal separation. She was persuaded to attempt to readjust the differences at home, and was successful in getting her husband's coöperation towards this end for the sake of the child. A fortnight later she announced that the stammer had disappeared as quickly as it had come. The left-handedness and squint remained unchanged. A few weeks later still, the left-handedness, too, had practically gone, and the squint, though present, was much less noticeable. A point bearing upon the possible relationship of the abnormalities to unhappy home conditions is the child's jealousy of her mother. If anyone in the family put his arm round the mother, the child would push him away in a passion, shouting "Go away, that is my mummie," and would cry if she were not obeyed. It should be added as an indication of the parental trends that the father used to stammer when a boy, and that the mother suffered from fits until the age of 7, and is still so afraid of the dark that she will never go upstairs without a lighted candle. Her eldest sister is partially left-handed—e.g., for cutting bread and peeling potatoes, but in her work as corset-maker is right-handed.

A similar instance of left-handedness on the female side associated with a family history of speech defect and squint, is the following:—

A girl, an only child, aged 6, has a left convergent squint and is left-handed. Her father has a left convergent squint. He has one brother, who is normal. His father and father's sister suffered from an impediment in speech. The child's mother is left-handed, and so is her maternal grandmother. The latter's two sisters were left-handed, but her two brothers were normal. It will be seen that the left-handed woman chose a squinting husband.

That the patient is unconscious of the emotional processes at work is shown by the following case:—

A woman of 28 consulted me a year ago. As she had a tendency to squint, I asked who was left-handed in the family. She replied that it was herself. Her father stammered when nervous. She has one brother, who had crystallised his stresses into a nervous breakdown and seasonal attacks of eczema. Being interested in the occurrence of these defects in her family, she asked if any practical value was likely to follow from their investigation, and I replied that I thought I could guess some of the attributes of her future husband. I applied the above simple formula, which is really a corollary to the Freudian theory that in marriage the girl tends to seek the father substitute, and the boy the mother. If the father is left-handed, and a fixation has occurred, the daughter is attracted by a left-hander, or a man of that characteristic temperament, and so forth. I described to my patient the stammering type in general terms, and ended by saying that in all probability her husband would stammer or squint. She then told me that she had just broken off an engagement of two years' standing, preferring to remain at home with her mother. As for the defect predicted, she stated: "Everyone used to say that he squinted, but I could never see it." She thus had a blind spot for a deformity, which is connected in some mysterious manner with abnormalities occurring in herself and her father.

The selection of like characteristics is not confined to adventures matrimonial.

I know of a stammering father who had a stammering son. This boy was sent successively to a kindergarten where the mistress stammered, and to a school with a stammering headmaster. He was subsequently articled to a well-known architect, who was similarly afflicted. When I first saw his wife I recorded that although the son did not marry a stammerer, he married into a stammering family, for his wife's only sister stammers very badly. Three years later the wife complained to me that owing to worry about her only child's health, she herself had begun to stammer slightly.

In a large number of cases of squint it has been rare to find instances in which only one member of the family has been affected. Sometimes there has been an only child, or there has been a considerable difference in age between the patient and the rest of the family. On the other hand, the incidence of squint in the family may be less than might be expected from the history of its occurrence in the preceding generation. A girl of 8 showed deviation only on alternate covering of the eyes, though she used to have a well-marked squint. She has two brothers and three sisters who are normal. Yet her father's eldest and youngest sisters and also a brother have convergent squint. There is no left-handedness or stammering in the family.

Occasionally I have found monocular amblyopia without sign of present or past squint, associated with one of the other two abnormalities. This occurred in a boy of 9, an only child, who was very hypermetropic, and had unequal pupils. He was left-handed, and so was the paternal grandfather, but not the father. The boy was very fidgety and nervous, and was described as being very resistant to his mother, who was "practically an invalid from nervousness." The left-handedness in this case may be due to disease, since the history showed that he had suffered from "infantile paralysis of the right leg," the effects of which, however, had completely disappeared. The case is now recorded, because although when tested he obviously wrote better with his right hand, and admitted that it was easier than with the left, he always used the latter for writing at home.

Nature of Emotion Influencing Squint.—As a rule the nature of the excitement influencing squint is not examined by the parents, and it is difficult for the surgeon to do more than surmise as to what is passing in the child's mind.

I have seen a little girl who squinted when she sat on my knee, and faced the father (of whom the child was afraid, according to the mother's account), and yet had straight eyes when she sat on her father's knee and, facing me, accepted my friendly overtures. Another child with a squint, restless in her mother's arms, and afraid of my approaches, lost the deviation when I tickled her and made her laugh. Yet another, with 6D hypermetropia in each eye, was brought to me with a history of a squint which, however, could not be evoked even when she was without her glasses, but appeared at once when I asked her to look at her mother and be scolded, the latter having previously told me that a reprimand often upset the balance of the eyes. The same result occurred in two boys of about 10, who had recently had operations for convergent squint. The resultant parallelism had been demonstrated to another observer who was sceptical of the theory here propounded. I suddenly spoke to the boys in a loud threatening voice, and both of them immediately relapsed into a bad squint, which slowly disappeared when they realised that I had been playing a trick upon them.

A suggestive example is that of a boy of 8, whose squint dates from a fit when 6 months old. The squint is never constant, but appears only when he is nervous—e.g., when meeting strangers. He was left-handed when a baby, but was checked. He has always ridden his scooter left-footed. He has only one brother, aged 17, who stammered when a child. The father's father squinted. It will be noticed that although the left-handedness has been eradicated, he still clings to left-footedness.

A similar emotional cause may be at work in these cases, as in a left-handed girl of 7, who was referred to me because she complained that large letters on the blackboard looked small, and vice versa. She was described as being very determined and independent. She had one brother who stammered occasionally. She confided to me that the ocular phenomenon, which lasted only one week, was due to jealousy, her little girl friend having chosen someone else to play with. In her own words, "she did not want to see things right."

The following case tends to confirm the opinion that deep-seated emotional reactions may be connected with the development and persistence of squint.

I have under my care at the present time a little girl of 2¼, who developed a squint at the age of 2. The curious thing about this squint was its regular appearance and disappearance on alternate days. If she squinted on Sunday, she did not on Monday, and so on. Cases have been reported of children who wrote on some days with the left hand, and on other days with the right. The only explanation which the mother could offer was her practice of keeping the children at home every other day, whilst she worked long and hard in order to be free to take them out of doors for a long spell the next day. On one occasion she reported to me that the father had been unwell, and had stayed in bed for the day. The little girl as a treat was allowed to have breakfast in bed with Daddy. It was her "squinting" day. The father whispered to the mother that there was no squint, and during the whole time in bed none developed. When, however, the mother came to fetch her away, the squint appeared, and persisted throughout the day, "according to plan."

The reactions of a child who developed a squint at a later age afford a better opportunity of studying possible emotional causes of the deviation.

A little girl of 6 began squinting during a fit of coughing, in June, 1919. The eyes became normal in the following months, but the squint recurred in the winter, and in February, 1920, she was taken to an oculist who prescribed R. and L. +1·5 sph. At that time she was seeing double. She was brought to me in August, 1921, when I found normal vision in each eye and 8° esophoria. Diplopia could be easily induced, fusion being obtained when the object was 1 metre distant. In the following winter she had whooping-cough, and it was noticed that after a fit of coughing a definite squint was present. As the effort to overcome 1·5D hypermetropia could have little effect in throwing the eyes off their balance, I advised that the glasses should be discarded. In August, 1922, she was again examined, and the esophoria now varied from 8° to 12° or more. She had previously told her father that she was anxious for the squint to be worse, as she particularly wished to wear glasses in order to be like her mother and brother. Occasional diplopia was complained of. At the next visit, in February, 1923, it was reported that although she had not worn glasses for over 12 months, she had been quite comfortable and without squint until two days previously, when the right eye had deviated inwards momentarily. On the following day she suddenly squinted badly with the right eye during a grammar lesson at school. The mistress told her not to squint, and she immediately began to see double. I inquired closely into the possibility of a sudden strain upon the accommodation at the time of onset of the squint, but found that the child had been quietly listening to a lecture by the mistress. When I asked what special part of the subject was being dealt with, the child replied "genders." She was described to me as of an exceptionally jealous disposition, and there had been trouble in the home when the father returned after several years' absence in the war, owing to her wish to monopolise the attentions of the mother. In February the mother was dying of cancer, and the domestic arrangements required that the little girl should sleep with the father. When she came for examination in March she entered my room without a trace of squint, but when attention was paid to her the right eye deviated inwards. She now gave the impression of being a precocious child. She was seen again in May, 1923. No squint had been noticed for some weeks, although she was still without glasses, until the morning of the consultation, when a marked squint had suddenly developed at school. She returned home with the *left* eye shut and the face screwed up. The mother had died early in March, and, the father having need of a holiday, it had just been decided that the child should be a boarder at the school for a time. The child tends to pick up things with her left hand. She has one brother, aged 15, who is reported to be "short-sighted" in one eye. The father has a slight stammer. He has three brothers, of whom the youngest stammers badly and has squinted, and three sisters who are normal.

Fear as a Cause of Squint.

Fear seems to be a potent cause of squint. I have seen many cases resulting from falls and blows, where it seemed justifiable to rule out the possibility of physical injury to the eye or anatomical nervous system.

A small boy had had a right convergent squint for a fortnight. Two weeks before its appearance he had bumped against another boy, whilst stealing out of the house in his night clothes, unknown to his mother, to buy sweets. He received a "black eye" on the right side, and was so thoroughly frightened, according to the mother (although he admitted it very reluctantly) that he screamed for two hours. He had suffered from twitching of the body and especially of the head for six months, and was very restless, indeed almost choreic, when seen at my clinic. The squint, which had certainly not been present before the accident, disappeared, but the restless movements continued. He cried much, was afraid of the dark, developed violent headaches and photophobia, and it was obvious that the mental shock had been severe. The family history revealed that of his two sisters one, aged 12, was "backward and dull and always ill," the other, aged 6, was attending the clinic with inflamed eyes, and the only brother, aged 11, was suffering from "nerves and heart and bad stammering." The father stammered, and the mother was left-handed.

I would draw particular attention to the occurrence of choreic movements in this instance. They have been present either in the patient or the family so frequently that I have thought it worth while to inquire, as a routine procedure, into their incidence, with the result that a number of cases showing their occurrence in squinting families has been collected.

One boy who came for treatment of occasional left squint developed a very pronounced twitching of the left side of face and body, following the application of atropine to the eyes. He became rapidly worse, and the twitching was soon so severe that the doctor diagnosed meningitis. The squint became permanent and greater in degree during the illness. The boy had two sisters, who were normal. The mother had four brothers, one of whom squinted, and six sisters, of whom the eldest was left-handed. It should be added that the father "suffered terribly from neurasthenia, and sometimes was not quite rational," after being in action at the Jutland battle.

It may be suggested that the onset of the chorea merely coincided with the use of the atropine. In favour of the possibility of an emotional factor being present, however, I would point to the cases, of which I have seen several, in which permanent squint has followed as a direct consequence of instilling atropine into the eyes of nervous children. One is apt to forget that the dread of interference with their eyes frequently shown by children is instinctive and not subject to reason. Indeed it is not unusual to find adults who cannot control their fear of the most gentle manipulation of their eyes, and who display the greatest dread of "going blind," although only temporarily, from the application of a mydriatic. The failure of accommodation, possibly associated with a fear corresponding to that of the strong man who faints when he is vaccinated, seems to be sufficient to cause serious disorganisation of the neuro-muscular function.

The influence of fear may be an explanation of the development of squint after whooping-cough, in which the paroxysmal attacks of asphyxiation must have a terrifying effect. I offer the same explanation to account for certain cases of squint following upon operations for tonsils and adenoids. An instance of this is a boy who had a right convergent strabismus after operation. At first inconstant, it became permanent. The boy's mother is left-handed.

Mirror-writing.

The tendency to mirror-writing in left-handers is so well known that it needs only a reference. A more uncommon attribute occurring in a left-hander is indicated in the case of a boy who was referred to me because he saw double. The natural inference was that he was developing squint and consequent diplopia, but investigation showed that when copying from the blackboard he doubled the letters and figures thus—229977 *for* 297; *in fact*, he might almost be described as having a "stammering" eye. He was the youngest of six, of whom all but the first two were left-handed until the age of seven or eight, when they became right-handed. All these left-handers have tended to write backwards, mirror fashion.

It happened that whilst I was engaged in investigating histories such as these, Dr. W. C. Rivers, tuberculosis officer of the Barnsley district, published an article in THE LANCET of Feb. 12th, 1921, in which he recorded cases where the whole family was exposed to infection, and only the left-handed members became tuberculous. He also noted that squint is two or three times as common in consumptives as in the general population. This widens the field of research almost illimitably. It would seem as if the squinter and left-hander had spent themselves under stresses the intensity of which cannot at present be estimated, and thereby rendered themselves more liable to infection, since it is impossible to conceive that left-handedness is itself a sign of deficient vitality. In other words, the connecting link between left-handedness, squint, and pulmonary tuberculosis will probably be found in the mental make-up of the individual rather than in his physical constitution.

This may seem a wild suggestion, yet a parallel may be found in the discussion on rheumatoid arthritis at the Royal Society of Medicine (Proceedings, November, 1923), when stress was laid upon the fact that the onset of the disease frequently coincided with some painful emotional experience. It is only fair to add, however, that so eminent an authority as Dr. Ernest Jones states in a verbal communication that after two years' psycho-analytical investigation of left-handedness he was unable to find a psychological factor in its development.

Conclusion.

The moral of the story seems to be two-fold: first, that these conditions, hitherto regarded as separate and unrelated, appear to be determined by defects in the personality as a whole, and secondly, that the emotional difficulties of the child in meeting social demands have an importance which has till now been hidden from all save the psycho-analyst.

PROBLEMS IN CONNEXION WITH THE DEBILITATED CHILD.

BY C. WILFRED VINING, M.D. LOND., M.R.C.P., D.P.H.,
HON. PHYSICIAN TO THE CHILDREN'S DEPARTMENT, LEEDS GENERAL INFIRMARY.

PROBLEMS in connexion with the debilitated states of childhood are continually being forced on the notice of those engaged in the care and treatment of sick children. A large proportion of the cases attending a children's out-patient department is made up of debilitated children with no gross physical signs. Whilst the reasons for their visits to the doctor vary, and whilst the children show differences in their histories and symptoms, yet analysis demonstrates the great frequency of certain main characteristics, and leads one to believe that there are important factors at work in the production of these debilitated states that are common to the majority of the cases. The importance of the recognition of these factors cannot be over-estimated, seeing the large amount of defective health found amongst children of school age, and the great possibility that from this arise certain more clearly defined conditions, of which rheumatism, chronic nervousness with its numerous manifestations, and tuberculosis may be mentioned as the more important.

Analysis of Histories, Symptoms, and Physical Abnormalities of Debilitated Children.

An examination of the histories of these children demonstrates the frequency of certain main symptoms. In the majority there is a history of wasting or refusal to gain weight, the development of an anæmic appearance, listless attacks, complaints of feeling the cold and being easily tired, indefinite pains about the limbs, and in some cases a history of "faints," giddiness, and pallor. Chronic digestive disorder is suggested by the frequent history of lost or capricious appetite, indefinite abdominal pain, chronic constipation, bilious attacks, and mucus and thread worms in the stools. A large proportion of these children are described as being nervous, timid, excitable, fidgety, and restless; and bed-wetting, nocturnal restlessness, night terrors, and the development of certain habits of movement are complained of in some of the cases. The actual combination of symptoms varies from case to case; it is, however, remarkable how frequently refusal to gain weight, loss of appetite, constipation, and nervousness occur together.

Clinical examination likewise reveals the frequency with which certain physical abnormalities are found. Most of the children are under weight and in poor physical health. They are pale and sallow, some have dark rings under the eyes, and occasionally the skin pigment is increased. There is a general want of tone in all the systems, but specially is this true of the muscular system and of the mucous surfaces. In the upright position there is an exaggeration of the natural curves of the body. Lordosis may be marked, and there is compensatory stooping of the shoulders with winging of the scapulæ. The abdomen is pushed forward with an appearance of enlargement when viewed from the front. In a considerable number of cases the abdomen actually is enlarged, often in striking contrast to the poorly covered chest wall. The abdominal fullness is due to two factors—namely, the tonelessness of the abdominal muscles, and the atonic distension of the bowel within. In many cases there is evidence of an unhealthy naso-pharynx, with or without enlargement of the tonsils and adenoid tissue. The deep sets of glands in the posterior triangles of the neck are enlarged and "shotty," and the glands in the axillæ, and to a less extent in the groins, are more palpable than those of the healthy child. There appears to be a generalised hyperplasia of the lymphatic glands, those, however, of the neck being specially prominent. A proportion although when tested he obviously wrote better with his right hand, and admitted that it was easier than with the left, he always used the latter for writing at home.

Nature of Emotion Influencing Squint.—As a rule the nature of the excitement influencing squint is not examined by the parents, and it is difficult for the surgeon to do more than surmise as to what is passing in the child's mind.

I have seen a little girl who squinted when she sat on my knee, and faced the father (of whom the child was afraid, according to the mother's account), and yet had straight eyes when she sat on her father's knee and, facing me, accepted my friendly overtures. Another child with a squint, restless in her mother's arms, and afraid of my approaches, lost the deviation when I tickled her and made her laugh. Yet another, with 6D hypermetropia in each eye, was brought to me with a history of a squint which, however, could not be evoked even when she was without her glasses, but appeared at once when I asked her to look at her mother and be scolded, the latter having previously told me that a reprimand often upset the balance of the eyes. The same result occurred in two boys of about 10, who had recently had operations for convergent squint. The resultant parallelism had been demonstrated to another observer who was sceptical of the theory here propounded. I suddenly spoke to the boys in a loud threatening voice, and both of them immediately relapsed into a bad squint, which slowly disappeared when they realised that I had been playing a trick upon them.

A suggestive example is that of a boy of 8, whose squint dates from a fit when 6 months old. The squint is never constant, but appears only when he is nervous—e.g., when meeting strangers. He was left-handed when a baby, but was checked. He has always ridden his scooter left-footed. He has only one brother, aged 17, who stammered when a child. The father's father squinted. It will be noticed that although the left-handedness has been eradicated, he still clings to left-footedness.

A similar emotional cause may be at work in these cases, as in a left-handed girl of 7, who was referred to me because she complained that large letters on the blackboard looked small, and vice versa. She was described as being very determined and independent. She had one brother who stammered occasionally. She confided to me that the ocular phenomenon, which lasted only one week, was due to jealousy, her little girl friend having chosen someone else to play with. In her own words, "she did not want to see things right."

The following case tends to confirm the opinion that deep-seated emotional reactions may be connected with the development and persistence of squint.

I have under my care at the present time a little girl of 2½, who developed a squint at the age of 2. The curious thing about this squint was its regular appearance and disappearance on alternate days. If she squinted on Sunday, she did not on Monday, and so on. Cases have been reported of children who wrote on some days with the left hand, and on other days with the right. The only explanation which the mother could offer was her practice of keeping the children at home every other day, whilst she worked long and hard in order to be free to take them out of doors for a long spell the next day. On one occasion she reported to me that the father had been unwell, and had stayed in bed for the day. The little girl as a treat was allowed to have breakfast in bed with Daddy. It was her "squinting" day. The father whispered to the mother that there was no squint, and during the whole time in bed none developed. When, however, the mother came to fetch her away, the squint appeared, and persisted throughout the day, "according to plan."

The reactions of a child who developed a squint at a later age afford a better opportunity of studying possible emotional causes of the deviation.

A little girl of 6 began squinting during a fit of coughing, in June, 1919. The eyes became normal in the following months, but the squint recurred in the winter, and in February, 1920, she was taken to an oculist who prescribed R. and L. +1·5 sph. At that time she was seeing double. She was brought to me in August, 1921, when I found normal vision in each eye and 8° esophoria. Diplopia could be easily induced, fusion being obtained when the object was 1 metre distant. In the following winter she had whooping-cough, and it was noticed that after a fit of coughing a definite squint was present. As the effort to overcome 1·5D hypermetropia could have little effect in throwing the eyes off their balance, I advised that the glasses should be discarded. In August, 1922, she was again examined, and the esophoria now varied from 8° to 12° or more. She had previously told her father that she was anxious for the squint to be worse, as she particularly wished to wear glasses in order to be like her mother and brother. Occasional diplopia was complained of. At the next visit, in February, 1923, it was reported that although she had not worn glasses for over 12 months, she had been quite comfortable and without squint until two days previously, when the right eye had deviated inwards momentarily. On the following day she suddenly squinted badly with the right eye during a grammar lesson at school. The mistress told her not to squint, and she immediately began to see double. I inquired closely into the possibility of a sudden strain upon the accommodation at the time of onset of the squint, but found that the child had been quietly listening to a lecture by the mistress. When I asked what special part of the subject was being dealt with, the child replied "genders." She was described to me as of an exceptionally jealous disposition, and there had been trouble in the home when the father returned after several years' absence in the war, owing to her wish to monopolise the attentions of the mother. In February the mother was dying of cancer, and the domestic arrangements required that the little girl should sleep with the father. When she came for examination in March she entered my room without a trace of squint, but when attention was paid to her the right eye deviated inwards. She now gave the impression of being a precocious child. She was seen again in May, 1923. No squint had been noticed for some weeks, although she was still without glasses, until the morning of the consultation, when a marked squint had suddenly developed at school. She returned home with the *left* eye shut and the face screwed up. The mother had died early in March, and, the father having need of a holiday, it had just been decided that the child should be a boarder at the school for a time. The child tends to pick up things with her left hand. She has one brother, aged 15, who is reported to be "short-sighted" in one eye. The father has a slight stammer. He has three brothers, of whom the youngest stammers badly and has squinted, and three sisters who are normal.

Fear as a Cause of Squint.

Fear seems to be a potent cause of squint. I have seen many cases resulting from falls and blows, where it seemed justifiable to rule out the possibility of physical injury to the eye or anatomical nervous system.

A small boy had had a right convergent squint for a fortnight. Two weeks before its appearance he had bumped against another boy, whilst stealing out of the house in his night clothes, unknown to his mother, to buy sweets. He received a "black eye" on the right side, and was so thoroughly frightened, according to the mother (although he admitted it very reluctantly) that he screamed for two hours. He had suffered from twitching of the body and especially of the head for six months, and was very restless, indeed almost choreic, when seen at my clinic. The squint, which had certainly not been present before the accident, disappeared, but the restless movements continued. He cried much, was afraid of the dark, developed violent headaches and photophobia, and it was obvious that the mental shock had been severe. The family history revealed that of his two sisters one, aged 12, was "backward and dull and always ill," the other, aged 6, was attending the clinic with inflamed eyes, and the only brother, aged 11, was suffering from "nerves and heart and bad stammering." The father stammered, and the mother was left-handed.

I would draw particular attention to the occurrence of choreic movements in this instance. They have been present either in the patient or the family so frequently that I have thought it worth while to inquire, as a routine procedure, into their incidence, with the result that a number of cases showing their occurrence in squinting families has been collected.

One boy who came for treatment of occasional left squint developed a very pronounced twitching of the left side of face and body, following the application of atropine to the eyes. He became rapidly worse, and the twitching was soon so severe that the doctor diagnosed meningitis. The squint became permanent and greater in degree during the illness. The boy had two sisters, who were normal. The mother had four brothers, one of whom squinted, and six sisters, of whom the eldest was left-handed. It should be added that the father "suffered terribly from neurasthenia, and sometimes was not quite rational," after being in action at the Jutland battle.

I would insist that tubercle, sufficient of itself to cause wasting, must be extensive, and its toxin must reach the tissue cell in considerable amount. If the tubercle is extensive enough to produce wasting at this age-period, the chances of recovery are poor, and the clinical signs of its existence should be present. That a considerable proportion of these children—about 60 per cent. of my own cases—give a positive tuberculin reaction I agree, and that a minority of the cases actually have local tubercular lesions of some group of glands I do not deny, but that the debility and health defect are due to tuberculosis in a large proportion of the cases I do not believe. To my mind, the tubercular lesion, if present, is more likely the result of the health defect than the cause of it. With reference to the incidence of tubercular lesions at this age-period, the following figures obtained from the post-mortem notes at the Leeds General Infirmary are of interest. During a period of 10 years, 563 children between the ages 5 and 15 were examined. 185 (32·8 per cent.) had tubercular lesions; excluding the cases where death had been directly due to tubercle, 86 (18·6 per cent.) had localised tubercular lesions, and of a series of 103 cases where death had been caused by accidents, 14 (13·5 per cent.) had local lesions.

In a considerable number of the cases the lesion merely consisted of one or two old calcified glands, and these figures are given to combat the statement that large numbers of school-children are suffering with tuberculosis or are harbouring local tubercular lesions.

It is, of course, important to be able to say whether tubercle is or is not present, and whether it is located in the mediastinal or abdominal glands, but clinical signs and tests are consistently unsatisfactory and a definite answer is often almost impossible. The important fact is to realise that the child's debility is due in the large majority of cases to factors not related to tubercle, and to treat accordingly.

Relationship of the Debilitated State with Nervous Instability.

Nervous affections are common amongst all classes of children, but specially is nervous instability and unrest found amongst debilitated children. The modern tendency appears to be to find explanation for nervous manifestations in mental processes, and to emphasise very forcibly the primary importance of the psychological factors. One is continually being forced to the conclusion that the majority of nervous children present clinical features that are impossible to explain by looking at the case from the psychological standpoint; and, in fact, it appears to me to be far easier to explain the nervous unrest and abnormal mental states as being in most cases secondary to physical ill-health.

In the histories of debilitated children evidence of nervousness in one way or another is consistently found. Timidity, fidgety states, habit spasm, nocturnal enuresis, night terrors, and peculiar likes and dislikes occur with considerable frequency, and can be explained by a combination of the nutritional defect, in which the nerve tissue is bound to partake, and the toxic factor, which produces a continuous irritation of the nerve cell. In the care and treatment of the child with inherited nervous instability the psychological factors in the production of nervous disorder are of first importance and cannot be neglected, nor can their importance be underrated in the treatment of the far larger number of nervous children belonging to the toxic debilitated class; but it has been my experience again and again to find that to under-estimate the meaning and importance of the physical abnormalities of this larger class is to miss the shortest way that will lead to a return to mental health.

Relationship of Rheumatic Affections of Childhood to the Debilitated State.

Important evidence in favour of a toxic factor as an explanation of many of the physical and nervous abnormalities of the debilitated child is provided by the relationship between the rheumatic and the debilitated state. The relationship between nervous disorders and chronic intestinal dyspepsia, on the one hand, and nervous troubles and rheumatism, on the other, has been stressed in the past. The nervous manifestations of both groups are practically identical. An examination of the histories of 100 consecutive cases of frank rheumatism and rheumatic heart disease in children showed in 82 of the cases definite evidence of ill-health preceding the first manifestation of rheumatism, and an analysis of symptoms of the disturbed health demonstrated the great frequency of wasting or refusal to gain weight, loss of appetite, constipation, anæmia, nervousness, headache, indefinite limb pains, tired feeling, and chronic cough. In 46 of the cases certain evidence of bowel catarrh previous to the first rheumatic attack was forthcoming, in 14 cases there was a long history of lost appetite and constipation, while in a further 12 cases evidence of bowel catarrh was found by an examination of the stools at the time of the active rheumatism. In 58 cases, therefore, certain evidence of bowel catarrh was obtainable, and if loss of appetite with constipation be accepted as evidence of chronic dyspepsia, then in 72 per cent. of the cases it was proved to be present, either before the first attack of frank rheumatism or at the time the child was under treatment for the rheumatism. The pre-rheumatic histories of 65 of the cases gave evidence of chronic nervous unrest. In only 10 cases was there a history of "sore-throat" preceding the first attack of rheumatism, although 37 of the children had enlarged tonsils at the time of examination and 15 of the cases had had their tonsils and adenoids removed at some previous date.

The following is a detailed analysis of the symptoms and abnormalities (other than those of the rheumatic infection) of 100 cases of rheumatism, and in order to compare the symptoms and abnormalities of the debilitated class an analysis of 100 cases, not specially chosen, belonging to this class is also given. It will be noticed that the figures for rheumatic cases are generally lower than those for the other class. This is partly due to the fact that in the earlier cases information as to many of the symptoms and abnormalities was not obtained, as neither the possible importance of the child's history during the years preceding the rheumatism, nor the likely relationship between the debilitated and the rheumatic child was then realised.

Comparative Analysis of (A) 100 Rheumatic Cases and (B) 100 Debilitated Cases.

Symptoms and abnormalities.	No. of times occurring amongst—		Symptoms and abnormalities.	No. of times occurring amongst—	
	(A)	(B)		(A)	(B)
"Wasting or not getting on" ..	36	40	Loss of appetite ..	45	59
Definitely under weight	45	54	Excessive appetite	11	8
Pallor	59	64	Abdominal pain ..	15	26
"Nervousness" ..	63	81	Constipation ..	46	47
Nocturnal enuresis	11	22	Loose stools ..	8	11
Night terrors ..	12	12	Mucus in stools ..	44	57
Habit spasm ..	5	13	Thread-worms ..	29	46
Limb pains	61	39	Catarrhal chest ..	13	15
"Always tired" ..	19	36	Dilated irritable heart	14	17
Listlessness	17	15	Palpable glands, neck, and axillæ	42	64
Headaches	17	21	Tonsils and adenoids ..	37	44
Bilious attacks ..	8	9			

By the term "frank rheumatism" is implied chorea, definite synovitis, with swelling of the joint, and rheumatic heart affection (permanent valvular lesion, pericarditis). The rheumatic manifestations were distributed as follows: Chorea alone, 31 cases; chorea and synovitis, 8; synovitis alone, 18; chorea and heart disease, 11; chorea, synovitis, and heart affection, 6; synovitis and heart affection, 21; heart lesion only, 5. The pre-rheumatic disturbed health of some 82 of these cases appears to differ in no way of the cases have quick irritable hearts, and the apex beat in a minority of the children is found to be outside the nipple line. There is often a short, frequent cough, occurring specially at night, and catarrhal sounds are not infrequently found in the chest. Timidity, restlessness, and occasionally habit spasm are noticed during the examination. As in symptoms, so in physical abnormalities, the combination varies from case to case, although deficient weight, toneless muscle, enlarged glands, and nervous unrest are found to occur together with monotonous frequency.

Possible Ætiological Factors in Production of Debilitated States.

Can the child's debility be explained by its environment? The fact that most of these cases are of the hospital class suggests at once that we are dealing with a condition engendered by defective hygienic surroundings; but that the environment is rather an intensifying than the chief factor is proved by the fact that typical examples are found amongst children of well-to-do parents living under the best conditions. If it can be shown that the child's diet is an important factor in the production of the debilitated state, then it is easily understood that the hospital child is more likely to suffer than the child of more fortunate parents.

It would appear to me that there are two chief causes at work, the one nutritional and the other toxic. The general tonelessness of the child and the relaxed mucous surfaces suggest at once a deficient nutrition of the tissue cell. That this is not due to insufficient food is proved by the inability of the parent to fatten the child by increasing its food, and the child's refusal to gain weight even when the appetite is excessive and food is taken freely. An increase in the daily quantity of milk is usually unsuccessful unless the child has been deliberately underfed, a condition of affairs which in my experience is quite exceptional. In the majority of hospital cases the parent is only too willing to give as much food, although unsuitable, as the child will take. The difficulty is that it so frequently has no appetite. I would suggest that the tissue cell defect is due to the cell being supplied over a long period of time with nutriment insufficient in some essential constituent or constituents, or a diet ill-balanced in its constituents, and later there arise from this a reduction and impairment in the secretory and absorptive powers of the bowel, due partly to the general tonelessness in which it also partakes and partly to a chronic catarrhal state set up by the prolonged unsuitability of the diet in the direction of gross relative excess in starches and sugar.

After the weaning period the majority of children are given a diet which, while sufficient in total calories, is overweighted with carbohydrate. The diet either contains too little animal protein and fat, or the relative excess of carbohydrate produces effects which render the other parts of the diet less useful. The diet of the present-day child, and specially the child of the hospital class, largely consists of bread, rusk, biscuit, potato, rice, sago, and other cereal, together with a quantity of sugar far in excess of its needs. The eating of sweets adds still more to the carbohydrate of the diet. With such a diet over a period of months or years, the tissue cell is bound to suffer, and it is to this that I would suggest a good deal of the child's tonelessness is due.

Many of the symptoms are difficult to explain except on the basis of a toxæmia. The headaches, the indefinite pains about the limbs, the colour of the skin, the listless attacks, the nervous instability and unrest, and the extensive glandular hyperplasia are all in favour of a prolonged toxic irritation. There are three places from which a toxin is likely to be absorbed—the bowel, the throat, and the urinary tract. In a considerable number of cases the naso-pharynx is unhealthy in the sense that the mucous membrane is relaxed, chronically inflamed, or the tonsils and adenoid tissue enlarged. As Dr. Lapage[1] has pointed out, hypertrophy of the tonsils and adenoid tissue need not necessarily be present when the naso-pharynx is unhealthy. The frequency with which the posterior cervical glands are enlarged suggests chronic absorption from the throat, although the increased palpability of the axillary glands tends to show that the toxic irritation of the lymphatic system is more generalised. Be this as it may, there can be no doubt that the throat is frequently a source of added toxæmia, specially in those cases with marked nervous unrest, and also, I think, in the cases with quick irritable hearts, to which Dr. Lapage has previously drawn attention.

In the care and treatment of these debilitated children, one is forced to the conclusion that most, if not all, are suffering from a persistently impaired digestion, due partly to the tissue cell defect already mentioned, but more especially to a chronic dyspepsia of the nature of a chronic mucous catarrh. In a good many cases there is clear evidence of this—the symptoms and the condition of the stools point to it. In a considerable minority there appears to be no direct evidence of dyspepsia, although there is frequently a history of prolonged constipation. Parents do not usually see their children's stools after infancy, and are willing to believe the child's bowel is working normally if on the child's evidence it is moved once daily. Such cases I have frequently had under observation in the ward, and have found that by washing the stool through muslin considerable quantities of mucus are present. It is not easy to define the varying characteristics of normal stools of children over the age of infancy, but I would claim that the presence of much undigested food, masses of jelly, and visible liquid mucus intimately mixed with the stool are abnormal and evidence of a chronic catarrhal state of the bowel. Severe examples of this condition are, of course, instances of the mucous disease described by the late Dr. Eustace Smith.[2] The great frequency with which bowel disturbance and constipation are found appears strongly to favour the intestinal tract as an important and probably the most frequent source of toxic absorption, and the results of treatment support this supposition.

Probable Sequence of Events in Production of Debilitated State.

As has already been suggested, there is probably a gradual bringing about of a general tissue cell defect by a prolonged inefficiency of the diet, and the mucous surfaces and glands soon lose tone and resistive power. Infections are with difficulty resisted and organisms and their toxins reach the lymphatic glands. I strongly support the view that the fundamental cause of the unhealthy throat and the tonsillar and adenoid hypertrophy is dietetic, the local resistance being lowered in the way indicated. The effects of infection and toxic absorption are added to the child's symptoms; but here again I would emphasise the belief that the main source of toxic absorption is in the bowel. The child's debility is still further increased by impaired digestion, due to the catarrhal state of the bowel, its toneless condition, and the frequency of intestinal stasis. Vicious circles are thus formed and the power of resisting toxins is greatly lowered.

Relationship between the Debilitated State and Tuberculosis.

In discussing the debilitated child the question of tubercle cannot be ignored. The wasting and the frequency of cough and catarrhal signs in the chest suggest to the parents, and sometimes to the doctor, the possibility of tubercle. Many of these cases are said to be infected with tubercle, to be suffering with tubercle, or are labelled as children with a pre-tubercular condition. The evidence is extremely unconvincing, and from experience in dealing with these children I am strongly of opinion that the large majority are certainly not suffering with tuberculosis.

---

[1] Brit. Med. Jour., July 2nd, 1921.

[2] The Wasting Diseases of Infancy and Childhood, 1870.

I would insist that tubercle, sufficient of itself to cause wasting, must be extensive, and its toxin must reach the tissue cell in considerable amount. If the tubercle is extensive enough to produce wasting at this age-period, the chances of recovery are poor, and the clinical signs of its existence should be present. That a considerable proportion of these children—about 60 per cent. of my own cases—give a positive tuberculin reaction I agree, and that a minority of the cases actually have local tubercular lesions of some group of glands I do not deny, but that the debility and health defect are due to tuberculosis in a large proportion of the cases I do not believe. To my mind, the tubercular lesion, if present, is more likely the result of the health defect than the cause of it. With reference to the incidence of tubercular lesions at this age-period, the following figures obtained from the post-mortem notes at the Leeds General Infirmary are of interest. During a period of 10 years, 563 children between the ages 5 and 15 were examined. 185 (32·8 per cent.) had tubercular lesions; excluding the cases where death had been directly due to tubercle, 86 (18·6 per cent.) had localised tubercular lesions, and of a series of 103 cases where death had been caused by accidents, 14 (13·5 per cent.) had local lesions.

In a considerable number of the cases the lesion merely consisted of one or two old calcified glands, and these figures are given to combat the statement that large numbers of school-children are suffering with tuberculosis or are harbouring local tubercular lesions.

It is, of course, important to be able to say whether tubercle is or is not present, and whether it is located in the mediastinal or abdominal glands, but clinical signs and tests are consistently unsatisfactory and a definite answer is often almost impossible. The important fact is to realise that the child's debility is due in the large majority of cases to factors not related to tubercle, and to treat accordingly.

Relationship of the Debilitated State with Nervous Instability.

Nervous affections are common amongst all classes of children, but specially is nervous instability and unrest found amongst debilitated children. The modern tendency appears to be to find explanation for nervous manifestations in mental processes, and to emphasise very forcibly the primary importance of the psychological factors. One is continually being forced to the conclusion that the majority of nervous children present clinical features that are impossible to explain by looking at the case from the psychological standpoint; and, in fact, it appears to me to be far easier to explain the nervous unrest and abnormal mental states as being in most cases secondary to physical ill-health.

In the histories of debilitated children evidence of nervousness in one way or another is consistently found. Timidity, fidgety states, habit spasm, nocturnal enuresis, night terrors, and peculiar likes and dislikes occur with considerable frequency, and can be explained by a combination of the nutritional defect, in which the nerve tissue is bound to partake, and the toxic factor, which produces a continuous irritation of the nerve cell. In the care and treatment of the child with inherited nervous instability the psychological factors in the production of nervous disorder are of first importance and cannot be neglected, nor can their importance be underrated in the treatment of the far larger number of nervous children belonging to the toxic debilitated class; but it has been my experience again and again to find that to under-estimate the meaning and importance of the physical abnormalities of this larger class is to miss the shortest way that will lead to a return to mental health.

Relationship of Rheumatic Affections of Childhood to the Debilitated State.

Important evidence in favour of a toxic factor as an explanation of many of the physical and nervous abnormalities of the debilitated child is provided by the relationship between the rheumatic and the debilitated state. The relationship between nervous disorders and chronic intestinal dyspepsia, on the one hand, and nervous troubles and rheumatism, on the other, has been stressed in the past. The nervous manifestations of both groups are practically identical. An examination of the histories of 100 consecutive cases of frank rheumatism and rheumatic heart disease in children showed in 82 of the cases definite evidence of ill-health preceding the first manifestation of rheumatism, and an analysis of symptoms of the disturbed health demonstrated the great frequency of wasting or refusal to gain weight, loss of appetite, constipation, anæmia, nervousness, headache, indefinite limb pains, tired feeling, and chronic cough. In 46 of the cases certain evidence of bowel catarrh previous to the first rheumatic attack was forthcoming, in 14 cases there was a long history of lost appetite and constipation, while in a further 12 cases evidence of bowel catarrh was found by an examination of the stools at the time of the active rheumatism. In 58 cases, therefore, certain evidence of bowel catarrh was obtainable, and if loss of appetite with constipation be accepted as evidence of chronic dyspepsia, then in 72 per cent. of the cases it was proved to be present, either before the first attack of frank rheumatism or at the time the child was under treatment for the rheumatism. The pre-rheumatic histories of 65 of the cases gave evidence of chronic nervous unrest. In only 10 cases was there a history of "sore-throat" preceding the first attack of rheumatism, although 37 of the children had enlarged tonsils at the time of examination and 15 of the cases had had their tonsils and adenoids removed at some previous date.

The following is a detailed analysis of the symptoms and abnormalities (other than those of the rheumatic infection) of 100 cases of rheumatism, and in order to compare the symptoms and abnormalities of the debilitated class an analysis of 100 cases, not specially chosen, belonging to this class is also given. It will be noticed that the figures for rheumatic cases are generally lower than those for the other class. This is partly due to the fact that in the earlier cases information as to many of the symptoms and abnormalities was not obtained, as neither the possible importance of the child's history during the years preceding the rheumatism, nor the likely relationship between the debilitated and the rheumatic child was then realised.

Comparative Analysis of (A) 100 Rheumatic Cases and (B) 100 Debilitated Cases.

Symptoms and abnormalities.	No. of times occurring amongst—		Symptoms and abnormalities.	No. of times occurring amongst—

Headaches	17	21	Tonsils and adenoids ..	37	44
Bilious attacks ..	8	9			

By the term "frank rheumatism" is implied chorea, definite synovitis, with swelling of the joint, and rheumatic heart affection (permanent valvular lesion, pericarditis). The rheumatic manifestations were distributed as follows: Chorea alone, 31 cases; chorea and synovitis, 8; synovitis alone, 18; chorea and heart disease, 11; chorea, synovitis, and heart affection, 6; synovitis and heart affection, 21; heart lesion only, 5. The pre-rheumatic disturbed health of some 82 of these cases appears to differ *in no way* from the manifestations of defective health found in the debilitated child, and in my opinion rheumatism is an infection developing in this type of child. It is of interest to mention that eight of the above rheumatic cases developed their first rheumatic attack during the time they were under treatment for chronic catarrh of the bowel, 4 cases; nervousness and habit spasm, 1; chronic constipation, loss of appetite, and nervous debility, 2; bilious attacks, nervousness, and wasting, 1.

Rheumatism in the child is an extremely insidious disease, and does not in the majority of cases behave at all like the usual type of infectious disorder. Its beginning is often difficult to define, relapses are common, it may smoulder for years, and occasionally the disease flares up dangerously and the child is placed in immediate jeopardy. A valvular lesion may develop without any preceding history of a frank rheumatic attack, as happened in five of my cases.

Since the research work of Poynton and Paine,[3] it has been accepted by all that rheumatism is due to an infection with an organism belonging to the streptococcal group of bacteria, although its exact type has still to be clearly defined, and such a conception of the ætiology of the disease fits in well with its clinical manifestations. It would seem as if the child harbours the rheumatic organism, which every now and then overcomes local resistance, and an attack of rheumatism occurs. Possibly at times only the toxin is at work, while at others the organism gains entrance to the tissues, or it may be that the pre-rheumatic disturbance in health is due to the toxin, and the rheumatism itself to the passage of the organism into the tissues.

The conception of the disease which I desire to put forward is that rheumatism is in most cases the result of a series of events which began some months or years earlier, and that the rheumatic stage has followed a stage of debilitated health during which a toxæmia has been in existence. "Growing pains" and fleeting indefinite pains about the limbs occur with great frequency amongst debilitated children, and can hardly be explained but by the influence of some toxic agent. The frequency with which a dilated irritable heart is found in the child with toxic debility and the acknowledged frequency with which the same type of heart is found in frank rheumatic infection may also be mentioned. It has always been held that the rheumatic toxin is specially liable to influence the cardiac muscle, apart altogether from any permanent affection, and I would suggest that the toxic rheumatic heart which rights itself after the rheumatic attack has come to an end is merely an exaggeration of the toxic irritable heart of some debilitated children.

Whether the rheumatic organism and its toxin enters the body via the naso-pharynx or the bowel must remain for the present undecided, although one would like to point out again that "tonsillitis" is by no means a very frequent accompaniment of rheumatism—at least it was not so in my series of cases—while, on the other hand, evidence of disturbed bowel occurs with great frequency both in the histories of debilitated children and in the pre-rheumatic history of the frankly rheumatic child. That the state of the bowel is the more important cause of debility is, in my experience, brought out by the results of treatment in this direction. Amongst my own cases the removal of tonsils and adenoids did not, in the majority of cases, produce any marked change, nor has the operation appeared to save some rheumatic cases from their rheumatism, for certainly 15 of these developed their rheumatism subsequent to the operation. On the other hand, treatment by strict dieting, persistent avoidance of constipation, and "bitter alkali rhubarb" mixtures produces in most cases a very marked improvement in a few months. I am in the habit of treating a debilitated child in this way even although I find no evidence of bowel catarrh, because the results are always strikingly better than those obtained by ordering extra milk, iron, cod-liver oil, &c., and lead me to believe that even in these cases the bowel is at fault, although there is no evidence of defect. From this it naturally follows that in the prophylaxis of rheumatism and a large amount of heart disease of young people, the control of the child's health—and particularly the provision of a well-balanced diet —during the years immediately following weaning are of the first importance.

Summary.

Problems in connexion with the debilitated child are discussed. The histories and physical abnormalities of these children are examined, and the frequency with which the same type of sign and symptom occurs is pointed out. It is suggested that the signs and symptoms are due to two main factors, the one nutritional and the other toxic, the child's tonelessness being due to the former and many of the symptoms to the latter. The nutritional factor is said to be due to a long-standing dietetic defect, together with the results of a chronic intestinal dyspepsia, while the toxic factor is believed to be due to the absorption of toxins from the throat and bowel, emphasis, however, being placed on the latter as the probably more important source. It is suggested that the unhealthy throat is secondary to the general tissue cell defect brought by the nutritional factor.

The relationship of tuberculosis, nervous disorder, and rheumatism to the debilitated state is examined. That the debility of these children is in the large majority of cases not due to tubercle is insisted upon, although the possibility of strictly localised tuberculous infection in some group of glands cannot be altogether denied. It is believed that in cases in which such an infection exists that the infection is secondary to the preceding lowering of resistance and tone.

A plea is put forward that the nervousness and nervous disorders of these children is secondary to the nutritional defect of the nerve cell and its irritation by toxins. Evidence is given to show that the rheumatic infection of childhood is in most cases ingrafted upon a preceding defect in health, which on analysis proves to be similar to the defects in health shown by the debilitated child, and it is suggested that in the prophylaxis and control of the rheumatic diseases the child's health in its earliest years is of the first importance, and emphasis is again laid upon the great importance of a well-balanced diet and the avoidance of chronic intestinal dyspepsia.

THE PHOSPHATE RATIO IN MENTAL DISEASE.

BY WILLIAM MOODIE, M.D. ST. AND.,
M.R.C.P., D.P.M. LOND.,
DEPUTY MEDICAL SUPERINTENDENT, HORTON MENTAL HOSPITAL, EPSOM;

AND

EILEEN A. BOYD, M.B., B.CH. DUB.,
CLINICAL ASSISTANT TO THE HOSPITAL.

THE investigations which form the basis of the following notes were prompted by some significant results obtained during the application of Sellards's alkali retention test[1] to a series of acute confusional mental cases of probably toxic origin. The mental state of many of these patients bears a marked resemblance to that observed in diabetes and other conditions of which acidosis is a feature; and it was seen, after only a small number of tests had been made, that there was frequently an abnormal alkali retention in confusional cases. The difficulty of administering exact quantities of alkali and of collecting specimens of urine at fixed times rendered it necessary, when dealing with mental patients, to simplify the procedure as far as possible from the patients' point of view, and, consequently, Sellards's method eventually gave place to a simple phosphate ratio estimation, using a standard technique.

---

[3] Researches on Rheumatism, 1913.

[1] Sellards: Bulletin Johns Hopkins Hospital, 1912, xxiii., 289.

In a most excellent "Study in Diabetic Acidosis," Calvert, Mayrs, and Milroy[2] have shown that the phosphate ratio in the normal subject is measurably altered by 1 gramme of sodium bicarbonate, and that this alteration reaches its maximum about three hours after the ingestion of the alkali. The technique is simple. 10 c.cm. of urine are diluted with 40 c.cm. of distilled water. This is then titrated with N/10 NaOH, using phenolphthalein as indicator. A few drops of a solution of methyl orange are added, and the mixture is titrated with N/10 HCl. The quantity of N/10 NaOH required is called "A" and of N/10 HCl "B." The phosphate ration is $\frac{A}{B-A}$ and the result is expressed as a fraction of 10. At first considerable difficulty was experienced in judging the end-points of the titrations, but latterly two estimations were carried out simultaneously on the same sample of urine and the tints compared. This was found to simplify the matter greatly.

The investigation has not been confined to cases of the confusional type, but the test was later applied to all cases admitted, irrespective of their type. A very large number of cases of all forms of mental disease have now been examined, and the results arranged in two groups—those which react normally to a dose of alkali by a definite drop in the numerical phosphate ratio after three hours, and those in which the ratio is almost or quite unchanged. Many of these cases have been under observation for over a year after the index was taken, and their subsequent history has thrown much light on results which, at first, appeared contradictory and confusing.

Acute confusional cases which appear clinically to resemble acidosis conditions invariably show little change in the phosphate ratio after ingestion of the alkali, and repeated tests in any one case during the acute stage of the disease always give results of about the same numerical value. Several confused patients whose phosphate ratio dropped, as in the normal individual, proved from their subsequent history to be cases of paraphrenia, dementia præcox, or manic depressive insanity. There would appear from our results to be few, if any, exceptions to the statement that every pure case of toxic confusional insanity gives a positive "acidosis" reaction. These cases generally clear up rapidly and make a good recovery without showing any appreciable mental deterioration after convalescence.

There is no other definite mental condition in which an acidosis reaction is commonly found, but it is very often the accompaniment of excitement from whatever cause, and is almost invariably present in this condition. Pure manic-depressives do not, in our experience, appear to develop acidosis. We have found a stationary phosphate ratio fairly frequently in cases of general paralysis of the insane, but only late in the disease, and usually associated with excitement. The acidosis reaction does not appear to be a feature of dementia, and confused senile cases without an acidosis reaction have always, after observation, shown themselves to be cases of pure dementia.

Three main conclusions may be arrived at from an analysis of our results: (1) There is a definite type of confusional insanity which always shows the "acidosis reaction." This occurs at all ages, and the prognosis is usually good. (2) The numerical value of the phosphate ratio remains very constant for each case during the confused period. (3) An "acidosis reaction" is not uncommon in excited states, but this does not apply to manic-depressives.

The phosphate ratio may, therefore, prove to be a valuable aid to prognosis, and we venture to submit these preliminary results in the hope that others may take up the work and that in this way a large mass of data may be collected. Several methods of combating the acidosis as a therapeutic measure have been devised, but it is, as yet, too early to express any definite opinion as to their efficacy.

A CASE OF ENDOCARDITIS TREATED BY IMMUNO-TRANSFUSION

WITH APPARENT RECOVERY.

By E. WORDLEY, M.C., M.D. CAMB., M.R.C.P. LOND.,
PATHOLOGIST, SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

IT is thought that a brief note on the following case will be of interest in view of the success of the treatment. The history is as follows:—

T. L., male, aged 37. He had pneumonia at 16 years, diphtheria at 20 years. In 1910, in Australia, he had an illness for which he was admitted to hospital. The symptoms were severe pains in the joints with general prostration, sweating, and fever. After three weeks in bed he was discharged. Almost immediately afterwards he again became ill with similar symptoms for two weeks. He was unable to get treatment at the time and states he took a considerable time to recover from the illness. In 1916 he joined the R.N.V.R. and served throughout the war, being able to carry out his duties perfectly. He was mostly in the Mediterranean area. During 1920, 1921, and 1922 he had several slight attacks of mild joint pains and slight fever. Each lasted about a week, but for all this period, except during these attacks, he was able to attend to business and to play games strenuously.

On Nov. 6th, 1923, he went to bed complaining of pains in the shoulders, wrists, and fingers; there was profuse sweating; the temperature was 102°F. He improved on treatment with salicylates and returned to work, though still feeling ill. On Dec. 20th he had to go to bed again. Sweating was again profuse. He had considerable fever, temperature rising to 102°–103° in the evening and dropping to almost normal in the morning. No abnormal physical signs had previously been noted, but there was now heard a reduplication of the first heart sound over the mitral area.

On Jan. 2nd, 1924, I saw the patient in consultation with Dr. B. B. Metcalfe, of Liskeard, Cornwall, to whom I am indebted for the clinical details and history and for permission to publish this note. A blood count showed leucocytes 6200 per c.mm., polymorphs 60 per cent., and lymphocytes 40 per cent. Agglutination reactions were done against the enteric and dysentery groups of organisms and also *M. melitensis* and *para-melitensis*, with negative results. A blood culture was sterile. The patient continued to have a high temperature. Rigors now occurred and he lost much weight. On Jan. 21st blood was again taken for culture and proved sterile. At this date numerous petechiæ were noted over the elbows, and later crops were seen over the arms and legs. His general condition was very bad. Frequent rigors occurred and the temperature was 103°–104° every evening. He was very weak. There was extreme pallor and some cyanosis, and he had wasted very considerably. The pulse was rapid and very feeble, and a soft murmur was noted following the first heart sound, and best heard over the mitral area.

Vaccine treatment in such desperate cases being so unsatisfactory, it was decided to try immuno-transfusion after the method described by Colebrook and Storer.[1] This first transfusion was given on Jan. 27th. Very briefly, the method is based on some observations of Sir Almroth Wright[2] [3] and his co-workers, who

[3] Wright, Sir A., Colebrook, L., and Storer, E. J. Ibid., 1923, i., 365, 417, 473.

or of organic disease of the nervous system was found in no less than nineteen-twentieths of the cases. Physical sequelæ are more common in adults, mental in children below the age of 10. A long interval between the acute stage and the appearance of further symptoms is associated with a serious and progressive sequela. Symptomatic paralysis agitans, usually progressive, occurs in more than one quarter of the cases. The prognosis must be very guarded even when complete recovery appears to have taken place.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XVIII.—MEDICAL EVIDENCE.

BY HUGH WOODS, M.D. DUB.,

GENERAL SECRETARY OF THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LTD.

> "It is true—without any slips of prolixity, or crossing the plain high-way of talk."—*The Merchant of Venice*, Act III., Sc. 1.

Compulsory Evidence.

MEDICAL practitioners, whether they like it or not, are frequently required to give evidence in the law courts. If summoned as witnesses in criminal cases they must attend, and when subpœnaed to give evidence in civil cases they cannot safely absent themselves. Failure to attend in a criminal case might entail arrest and fine or imprisonment; and, in a civil case, damages might be recovered from the absentee for any loss arising from the lack of the evidence which he would have given if he had obeyed the subpœna. The only way to avoid the risk of being compelled to give evidence is to keep clear of being in a position to give evidence in a matter likely to be the subject of legal proceedings. The probability of being called as a witness is greatly increased if it is known what evidence would be given. This should be borne in mind when a request is made for a report on a case which may lead to litigation. Before a report is given a guarantee should be required that an adequate fee will be paid, not only for the report, but also for giving evidence or attending to give evidence in the event of legal proceedings. After a report has been given the vantage ground for negotiating for a fee above the minimum amount legally prescribed has been lost. In the event of a patient requiring the evidence of the medical attendant to establish a proper claim it would not be fair to raise any unreasonable difficulty, but in the large number of cases where medical practitioners are not bound in duty to give evidence they will be wise to take precaution to enable them to do as they choose in regard to giving evidence, and to safeguard their position in the matter of proper remuneration if they are willing to be witnesses.

Allowances to Practising Members of the Medical Profession for Attending to Give Professional Evidence in Criminal Prosecutions.

For attending to give evidence in the town or place where the witness resides or practises—

If the witness attends to give evidence in one case only, not more than one and a half guineas per diem.

If the witness gives evidence on the same day in two or more separate and distinct cases, not more than three guineas.

For attending to give evidence elsewhere than in any town or place where the witness resides or practises, whether in one or more cases, not more than three guineas per diem. "Town" means municipal borough or urban district: and "place" means within a radius of three miles from the court at which the witness attends to give evidence.

There may be allowed to expert witnesses such allowances for attending to give expert evidence as the court may consider reasonable, including, where necessary, an allowance for qualifying to give evidence.

No full day allowance shall be paid unless the witness is necessarily detained away from his home or place of business or employment for at least four hours for the purpose of giving evidence. If the time is less than four hours the witness shall receive not more than one-half of the allowances which he would have received if he had been detained for the full day.

For attending court from a distance of over two miles there may be allowed:—

To witnesses travelling by railway or other public conveyance, the fare actually paid.

Railway fares, except for special reasons allowed by the court, shall be third class; and if return tickets are available, only return rates are allowed. Where no railway or other public conveyance is available, and one or more witnesses necessarily travel by a hired vehicle, the sum actually paid for the hire of such vehicle, not exceeding *1s. 6d.* a mile each way, is allowed, provided that, where two or more witnesses attend from the same place, the total allowance shall not exceed *1s. 6d.* a mile each way unless the court is satisfied that it was reasonably necessary to hire more than one vehicle.

To each witness travelling on foot, or by a private conveyance, where no railway or other public conveyance is available, a sum not to exceed *3d.* a mile each way is allowed.

Witness Fees in the High Court.

In the High Court the witness fees payable to a non-expert medical witness—that is, a witness of fact—are from one to three guineas, and in some cases the Taxing Master will allow five guineas. A witness attending the High Court is entitled to receive a sufficient amount of conduct money to take him to the court, and if there is any doubt in his mind as to the amount, or as to provision for his witness fees, he can raise the matter in court prior to his giving evidence. When a medical practitioner is called solely as an expert the amount of his fee is a matter of private arrangement between him and the persons calling him. He is entitled to a fee for qualifying (i.e., studying the subject so as to be competent to give expert opinions on questions arising) and for attendance, and he can refuse to give any evidence unless adequate provision has been made for his fees, or he can demand their payment before giving any evidence at all.

Non-Expert Evidence.

Non-expert evidence from a medical man is a bare statement of the facts found by him, and if called as a non-expert witness he is not bound to give his opinion and deductions based on the facts which were present to him. It is difficult for a medical man to draw a hard-and-fast line, and he should, of course, in ordinary cases, where he is called as a witness of fact, be as helpful to the court as he can in the evidence he gives.

The Importance of Being Understood.

A medical witness should carefully avoid conveying to judge and jury the impression that he thinks they know but little of medical matters; but at the same time he should not reckon on their having any sound knowledge on medical subjects. They may not be as ignorant as the coroner's jury which gave a verdict that a man had died from a stone in the kidney swallowed by him when lying in a state of intoxication on a gravel path, but it is best to guard against possibilities of profound ignorance or curiously absurd notions. Even if a medical witness is able to avoid technical terms, and to give his evidence clearly and accurately in ordinary language, there is still grave danger of serious misconception on the together with the full bibliography, have already made it essential to any worker in this still extremely controversial field.

In general arrangement the second edition does not differ from the first. As before, the book is divided into three parts: (1) The chief facts of normal colour-vision; (2) the chief facts of colour-blindness; and (3) the chief theories of colour-vision. The value of the second edition lies in the fact that the references have been brought completely up to date, and that all the important recent work on the subject has been incorporated. In particular, the inclusion of discussions on the later results of such scientists as Abney and Watson, Luckiesh, Pulfrich, and Ives may be mentioned. Additions naturally occur most frequently in Section I., and here many new curves and tables are found. Among others, the energy distribution curves of various illuminants, the work of Abney and Watson on threshold stimuli at the fovea, Luckiesh's method of study of the growth and decay of colour sensation by means of flicker, and Pulfrich's ingenious stereoscopic indicator for studying differences of brightness are well described. In the portion of the book devoted to theory there is little change, except for a more detailed discussion of Edridge-Green's views and the incorporation of Houston's vibratory theory.

ICARUS, OR THE FUTURE OF SCIENCE.

By **Bertrand Russell**. London: Kegan Paul, Trench, Trübner and Co. 1924. Pp. 64. 2*s.* 6*d.*

Mr. Haldane's "Dædalus" has roused a good many people, among them Mr. Russell, who here makes what is in some measure a reply to that bright *jeu d'esprit*, which, it will be remembered, imagines a prosperous future for human progress under the guidance of biological discovery. Mr. Russell puts on several belts as well as his braces, and draws a gloomy picture of the probable fate of men whom modern science has taught to fly. It is naturally less attractive and stimulating than the work of Mr. Haldane, who does not seem to care much what happens to his trousers so long as he gets forward. Pessimism always makes rather poor reading. Mr. Russell's main point is that the chief effect of science is to give men power to achieve their desires. He mistrusts man and doubts whether he will use his power wisely. In a few pages he covers a large field of great topics, and the treatment is necessarily brief and, indeed, does not amount to much more than a statement of the author's conclusions. The result will be disappointing to those who have been charmed and convinced by his more solid writing.

UROLOGY.

Modern Urology. Second edition. By many American Authors. Edited by **Hugh Cabot**, C.M.G., M.D., F.A.C.S., Dean and Professor of Surgery in the Medical School of the University of Michigan. Philadelphia and New York: Lea and Febiger. 1924. In two volumes. Pp. 828 and 744. $18.

This System of Urology, though written first only five years ago, has come to a second edition, partly because of its merits, but also because urology continues to make such progress that revision soon becomes a necessity. Certain changes are made in this edition, and to keep the size of the book within the same limits as before the historical sketch of genito-urinary surgery in America has been omitted. Two of the original contributors have died, and their work has been revised by others.

Hugh Cabot is to be congratulated on having collected together articles from so many pens, and at the same time produced a book which keeps the same high level throughout. There is some overlapping as in every System, and if space is urgently needed, as the preface suggests, there is plenty to be had by cutting duplicate descriptions. Of these the most prominent example is the perineal prostatectomy operation, which is described at great length by two authors, with numerous illustrations, most of which occur twice. But this is a small matter, and in no way detracts from the quality of the work. It is well written, very well illustrated, and has a bibliography at the end of each chapter. It should prove of great value to any surgeon who takes up urology as his special subject.

Kystoskopischer Atlas. Third edition. By **Erich Wossidlo**. Berlin and Leipsic: Wilhelm Engelmann. 1924. With 43 coloured plates. Pp. 111. 35 gold marks.

This third edition has been slightly altered in the text and somewhat rearranged. The collection of cystoscopic drawings in colour is really very fine, and for these alone the book is a welcome possession. The appearance of another edition so shortly after the second is evidence of the success of this atlas.

JOURNALS.

Brain. Vol. XLVII., Part 1.—The Pathogenesis of Cerebral Diplegia, by James Collier. This presidential address to the Neurological Section of the Royal Society of Medicine was printed in The Lancet of Nov. 24th, 1923. The thesis is maintained that true cerebral diplegia is the result of primary degeneration of the cerebral neurons. The causal agent is unknown except in certain rare cases of syphilitic infection.—On the Dissociation of Voluntary and Emotional Innervation in Facial Paresis of Central Origin, by G. H. Monrad-Krohn. A description of four cases showing acceleration and exaggeration of emotional movements of the face combined with voluntary paresis in the same distribution. This suggests that the emotional motor apparatus is distinct from the voluntary motor apparatus, and is normally subjected to a continuous inhibition by the latter. Further, the lenticular nucleus in its pallidal part probably contains the motor centre for emotional innervation.—The Pathological Anatomy of Disseminated Sclerosis, by C. P. Symonds. As the result of a thorough examination of a typical case which died during an acute exacerbation of the disease, the author is able to demonstrate the presence of perivascular infiltration with lymphocytes and plasma cells. He concludes that the disease is infective in origin, but he was unable to find spirochætes or other micro-organisms. The paper is well illustrated.—A Study of the Electromyograms of Voluntary Movement, by F. Golla. The muscular coördination taking place in voluntary movements was investigated by recording the muscle action-current and the muscle sound. It was found that in the coöperation between anatomically antagonistic muscles their time relations and the magnitude of their response is adjusted with an almost infinite variation to the different degrees of resistance that the voluntary movement may be called upon to overcome, or to the velocity with which it is performed. The effective mechanism of voluntary control appears to determine, in the first place, the nature, velocity, and force of any given voluntary movement, but plays no part in the determination of such modifications as may be necessary in the first instance to deal with the variations of the environment which may be encountered during the performance of the movement.—Electromyographic Studies of Experimental Convulsions, by Stanley Cobb. Thujone injections were used to produce convulsions in rabbits. The records obtained show that both the tonic and clonic parts of the fit are tetanic in character.—The Sequelæ of Encephalitis Lethargica, by A. G. Duncan. Of 136 consecutive cases 35 died; of the remainder, 83 were traced for at least 18 months after the onset of the disease. Evidence of mental impairment or of organic disease of the nervous system was found in no less than nineteen-twentieths of the cases. Physical sequelæ are more common in adults, mental in children below the age of 10. A long interval between the acute stage and the appearance of further symptoms is associated with a serious and progressive sequela. Symptomatic paralysis agitans, usually progressive, occurs in more than one quarter of the cases. The prognosis must be very guarded even when complete recovery appears to have taken place.

The Conduct of Medical Practice.

A Series of Articles by Experts dealing with the Difficulties Encountered in Professional Life and How to Meet Them.

XVIII.—MEDICAL EVIDENCE.

BY HUGH WOODS, M.D. DUB.,
GENERAL SECRETARY OF THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LTD.

"It is true—without any slips of prolixity, or crossing the plain high-way of talk."—*The Merchant of Venice*, Act III., Sc. 1.

Compulsory Evidence.

MEDICAL practitioners, whether they like it or not, are frequently required to give evidence in the law courts. If summoned as witnesses in criminal cases they must attend, and when subpœnaed to give evidence in civil cases they cannot safely absent themselves. Failure to attend in a criminal case might entail arrest and fine or imprisonment; and, in a civil case, damages might be recovered from the absentee for any loss arising from the lack of the evidence which he would have given if he had obeyed the subpœna. The only way to avoid the risk of being compelled to give evidence is to keep clear of being in a position to give evidence in a matter likely to be the subject of legal proceedings. The probability of being called as a witness is greatly increased if it is known what evidence would be given. This should be borne in mind when a request is made for a report on a case which may lead to litigation. Before a report is given a guarantee should be required that an adequate fee will be paid, not only for the report, but also for giving evidence or attending to give evidence in the event of legal proceedings. After a report has been given the vantage ground for negotiating for a fee above the minimum amount legally prescribed has been lost. In the event of a patient requiring the evidence of the medical attendant to establish a proper claim it would not be fair to raise any unreasonable difficulty, but in the large number of cases where medical practitioners are not bound in duty to give evidence they will be wise to take precaution to enable them to do as they choose in regard to giving evidence, and to safeguard their position in the matter of proper remuneration if they are willing to be witnesses.

Allowances to Practising Members of the Medical Profession for Attending to Give Professional Evidence in Criminal Prosecutions.

For attending to give evidence in the town or place where the witness resides or practises—

If the witness attends to give evidence in one case only, not more than one and a half guineas per diem.

If the witness gives evidence on the same day in two or more separate and distinct cases, not more than three guineas.

For attending to give evidence elsewhere than in any town or place where the witness resides or practises, whether in one or more cases, not more than three guineas per diem. "Town" means municipal borough or urban district: and "place" means within a radius of three miles from the court at which the witness attends to give evidence.

There may be allowed to expert witnesses such allowances for attending to give expert evidence as the court may consider reasonable, including, where necessary, an allowance for qualifying to give evidence.

No full day allowance shall be paid unless the witness is necessarily detained away from his home or place of business or employment for at least four hours for the purpose of giving evidence. If the time is less than four hours the witness shall receive not more than one-half of the allowances which he would have received if he had been detained for the full day.

For attending court from a distance of over two miles there may be allowed:—

To witnesses travelling by railway or other public conveyance, the fare actually paid.

Railway fares, except for special reasons allowed by the court, shall be third class; and if return tickets are available, only return rates are allowed. Where no railway or other public conveyance is available, and one or more witnesses necessarily travel by a hired vehicle, the sum actually paid for the hire of such vehicle, not exceeding 1*s.* 6*d.* a mile each way, is allowed, provided that, where two or more witnesses attend from the same place, the total allowance shall not exceed 1*s.* 6*d.* a mile each way unless the court is satisfied that it was reasonably necessary to hire more than one vehicle.

To each witness travelling on foot, or by a private conveyance, where no railway or other public conveyance is available, a sum not to exceed 3*d.* a mile each way is allowed.

Witness Fees in the High Court.

In the High Court the witness fees payable to a non-expert medical witness—that is, a witness of fact—are from one to three guineas, and in some cases the Taxing Master will allow five guineas. A witness attending the High Court is entitled to receive a sufficient amount of conduct money to take him to the court, and if there is any doubt in his mind as to the amount, or as to provision for his witness fees, he can raise the matter in court prior to his giving evidence. When a medical practitioner is called solely as an expert the amount of his fee is a matter of private arrangement between him and the persons calling him. He is entitled to a fee for qualifying (i.e., studying the subject so as to be competent to give expert opinions on questions arising) and for attendance, and he can refuse to give any evidence unless adequate provision has been made for his fees, or he can demand their payment before giving any evidence at all.

Non-Expert Evidence.

Non-expert evidence from a medical man is a bare statement of the facts found by him, and if called as a non-expert witness he is not bound to give his opinion and deductions based on the facts which were present to him. It is difficult for a medical man to draw a hard-and-fast line, and he should, of course, in ordinary cases, where he is called as a witness of fact, be as helpful to the court as he can in the evidence he gives.

The Importance of Being Understood.

A medical witness should carefully avoid conveying to judge and jury the impression that he thinks they know but little of medical matters; but at the same time he should not reckon on their having any sound knowledge on medical subjects. They may not be as ignorant as the coroner's jury which gave a verdict that a man had died from a stone in the kidney swallowed by him when lying in a state of intoxication on a gravel path, but it is best to guard against possibilities of profound ignorance or curiously absurd notions. Even if a medical witness is able to avoid technical terms, and to give his evidence clearly and accurately in ordinary language, there is still grave danger of serious misconception on the part of people whose medical knowledge is chiefly derived from quack advertisements, or other sources not more trustworthy than them. Where it is possible, a medical witness should provide himself with specimens, models, or pictures, which will make clear many points which no words would ever make intelligible. The details of a fracture of the wrist will be much better understood, for instance, if the medical witness can explain them with the help of articulated bones, and preferably ones showing a fracture similar to that which is under discussion.

Answering—Yes or No.

The rule that answers to questions should be direct and definite applies to medical evidence, but the difficulty of adhering to that rule is often very great for medical witnesses. Questions are often put—sometimes perhaps intentionally—direct answers to which, without qualification, might convey a very wrong impression. Nevertheless, there is no worse witness than one who answers questions hesitatingly and indefinitely, and then delivers a short lecture with a view to explaining his meaning. This kind of evidence gives excellent opportunities for cross-examination, and often ends in serious discomfiture of the witness with consequent damage to the case which his evidence should have supported. There are many questions which a witness cannot rightly answer by a simple Yes or No. If a witness is asked whether the habit of stating as facts things which are obviously untrue indicates the existence of insane delusions, he ought certainly not to answer simply Yes or No. The answer should be that it may or may not, and the witness can then wait for further questions and continue to answer them as directly and simply as possible. If instead of this he attempts to set out the methods by which distinction can be made between habitual lying and the truthful expression of unfounded imaginations he will run great risk of failure, involving him in ridicule and discrediting him as a witness.

Expert Witnesses.

It is a common reproach to medical as well as other expert evidence that it can be obtained in support of almost any proposition or theory which it is desired to establish, and it happens too often that expert witnesses of good standing confidently express diametrically opposite opinions on a subject which is undergoing legal investigation. The result of this may be the complete cancelling out of the expert evidence, leaving the matter quite undecided; or the question—which expert is right, and which wrong—may be decided by persons not at all competent to decide where doctors disagree. It is not much to be wondered at that experts support the point of view of those who call them as witnesses, because it is usual, before calling an expert witness to give evidence in a case, to ascertain what his opinion will be on the more material points. If his views are not favourable to the case of those proposing to call him as a witness, he is not asked to give evidence, and search is made for an expert whose evidence is likely to be helpful. Consequently, if any suitable expert can be found who is prepared to give evidence such as is desired he is likely to be summoned as a witness. Without such previous selection there would be less conflict of opinion.

Should Medical Witnesses Confer Together?

There can be no doubt that the medical evidence in many cases would be more consistent and more satisfactory if the medical witnesses conferred together before giving evidence, and not infrequently, in cases depending chiefly on the medical evidence, such conference would lead to a settlement without the trouble and expense of a trial. In a case, for instance, in which it was contended on the one side, and denied on the other, that serious consequences were due to injury of a nerve in the course of an operation, a consultation of the medical witnesses, with further investigation of the case, led to their arriving at the same conclusion, and obviated the necessity for further legal proceedings in the matter. When there is a real desire or willingness that a dispute should be decided justly on its actual merits there seems to be no sound objection to a conference of proposed medical witnesses beforehand, whether such witnesses will be called upon to give expert evidence or merely to give evidence of fact as to the condition of a person determined by medical examination.

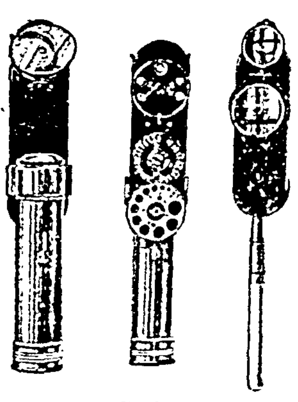
Medical Evidence should be without Bias.

A medical witness is usually called to give evidence on behalf of one side in a law case and not both, and he is often a witness for one of his own patients. This should not cause him to feel or show any desire to favour the side for which he is a witness at the expense of the other side. He should, of course, do his best to give his unbiased evidence fully and satisfactorily on behalf of those who, more or less, may depend on his evidence for the success of their case, and he has no duty towards the other side beyond that of honesty and fair dealing. Consideration of the interests of those for whom he is giving evidence should, of itself, prevent his showing any signs of bias while giving evidence. A medical witness should especially be on his guard in this respect when being cross-examined. The knowledge that cross-examination is intended to detract from the force of evidence given, and perhaps to discredit the witness himself, often leads that witness—sometimes unconsciously—to assume a hostile demeanour which serves only to assist the cross-examiner in his task. While, of course, guarding against snares, which are not likely to be laid for him except in the cross-examination, the witness should answer the cross-examiner with the same readiness and courtesy as when giving his answers to those conducting the case for the side on which he is giving evidence.

New Inventions.

A NEW OPHTHALMOSCOPE ATTACHMENT.

THE accompanying diagram represents a simple method of converting and re-converting at will, in less than one minute, the ordinary Standard Morton ophthalmoscope into the well-known "Fundus Aurorascope" (the instrument by which a novice can see at the bedside every detail of the fundus oculi). A front and back view is illustrated. The conversion which has been designed by me is very simple. The retinoscopic and small mirrors of the Morton ophthalmoscope are detachable by a slide movement and in its place a concave mirror set at an angle of 45° is fixed. This piece is now attached by a grooved socket on the small pocket-torch handle containing a three-volt battery and a switch. This instrument will be found invaluable at the bedside as it obviates the skill which is necessary for a fundus examination with the ordinary Standard Morton, difficulties which, to other than a specialist, require considerable practice.



Front. Back.

The instrument has been made for me by the Aurorascope Co., Ltd., Fulwood House, Fulwood-place, Holborn, W.C. 1.

HENRY DUTCH, M.R.C.S.

THE LANCET.

LONDON: SATURDAY, AUGUST 2, 1924.

THE TEACHING OF HEALTH IN SCHOOLS.

AT a meeting of the Headmasters' Conference held in Winchester last year it was agreed that systematic teaching of hygiene ought to form part of the instruction of every boy during his time at school, and the Conference authorised the publication of a syllabus[1] which has been drawn up by medical experts for the benefit, in the first instance, of the members of the Conference this year. It is a guide for those who have to teach the theory and practice of healthy living to school-children of various ages and both sexes; and covering as it does a wide range, it is necessarily framed in general terms. In successive chapters the organisation of our public health service, housing, water, sewage, general biology and physiology, infectious diseases, exercise, fresh air, cleanliness, food, drink, and heredity are dealt with. The pamphlet concludes with a long list of books likely to prove useful to the teacher.

Education finds any justification it may need in the progressively increasing intelligence of successive generations. The boys and girls of to-day are, without doubt, quicker at learning than were their parallels of 20 and 40 years ago, and the reason of this is the greater independence which they enjoy, and, particularly, the better informed milieu in which they generally find themselves. But it is difficult to believe that they can possibly absorb a course such as is outlined in this syllabus, and we trust that headmasters and headmistresses will hesitate before suggesting that a valuable pamphlet should be used in any other way than as an indication to their staffs that practical health lessons can be conveyed in the course of the ordinary curriculum by teachers who are adequately informed. Pupils instructed directly from such a book as this would have a superficial, scrappy acquaintance with things they did not understand, and to import this serious disease of smattering, which is allowed by America to have affected their system of education, into seminaries of sound learning and religious education (such as still exist in this country) would be, we believe, a profound mistake from both the educational and hygienic points of view. No one questions the desirability of every young person having an elementary knowledge of human anatomy and physiology, of why one eats and what are useful foods, of what urine and fæces represent, of why it is well to wash, of the possibility of contracting some diseases by going too near other people who have them—and so forth. But to import into the school curriculum the pithy summary of the pathology of tuberculosis—admirable in itself—or the consideration of the results of mating allelomorphic pairs is verging on the absurd. We wonder, too, who is to teach up to this standard. We do not lose sight of the fact that the knowledge is to be imparted through the medium of the instructor, and after proper transmutation, but we wonder how many of our public schools, such as were represented at the Conference, possess the necessary staffs and equipment. The prefatory paragraphs of the syllabus rightly say that the teacher should be saturated with his subject. No good teaching, even of the most elementary kind, can, of course, be done otherwise, but a sound knowledge of the topics covered in the syllabus would imply the services of the experienced staff of a school of hygiene with a liberal idea of the confines of the subjects; such knowledge will scarcely be found among the staff of any ordinary—or, indeed, extraordinary—public school.

The document is framed on an impracticable scale. It starts with the proposition that "the science and art of healthy living . . . . is the most vital and human subject of the whole curriculum," which, if words are used in their common meanings, is either a patent extravagance or a sadly materialistic interpretation of the purpose of education. And if the scheme as outlined is to be carried through, it can only be by one of those illusory royal roads to learning which end in no sound permanent knowledge. The methods of healthy living, if they are to be of real use in later life, must be ground in with a thoroughness which makes them second nature, practised without deliberate thought, as the multiplication table is followed, and as the principle of asepsis is ground into medical students and surgical nurses. And in respect of health doctrines all that can possibly be imparted to the bulk of a school population would be the barest elements. Which is the more to be regretted, because the teaching of hygiene is a really important thing, and the ideal that all young citizens should start on the right road in the subject is one which is worth a great deal of trouble to achieve. The syllabus, we fear, would do little more than confirm the lay educationalist in the view, which he very likely holds already, that doctors are impracticable faddists.

◆

SQUINT, LEFT-HANDEDNESS AND STAMMER.

A RELATION has long been suspected between stammer and left-handedness, or mancinism, and on another page of this issue Dr. W. S. INMAN suggests that, with the addition of squint, they are alternative expressions of emotional states. It will be admitted that, in some people at least, stammer expresses emotion, and its appearance on specific occasions—in the presence of superiors, for example—must be regarded as a reaction of the whole personality. The patient himself is producing it, whether by contracting his diaphragm, closing his glottis, tightening his lips, or by other actions in themselves physiologically normal and capable of imitation by the non-stammerer. *Why* he does it is a question that our present knowledge allows us to answer only in terms of mental processes. But the case of mancinism seems very different, and the suggestion that it also may be of emotional significance will be new to most of us.

A letter which appears in our correspondence columns offers the generally accepted physiological explanation of mancinism and extends it to account for the onset of stammer after the successful restraint of the left-handed activities. The experiment reported by Mr. HUGH GORDON, and detailed by Dr. INMAN in his communication, seems also to support the view that, since speech depends upon the integrity of the left side of the brain in right-handed people and upon that of the right side in left-handers, the transfer of dominance from one hand to the other somehow involves the speech area of the cortex and causes a stammer. But a pure left-hander is rare, and, as Dr. INMAN shows, there is a notable specificity in left-handed activities. If these depend upon physiological causes, they demand a selective subtlety on the part of nerve cells which passes comprehension.

HENRY DUTCH, M.R.C.S.

Council the decision as to whether certain conduct should or should not have occurred, and, having occurred, did or did not call for disciplinary interference.

With regard to the question of the appearance of names at the foot of letters or articles in the public press, the iniquity, according to Dr. H. B. BRACKENBURY, lies in the insertion of address, photograph, and titles; and here we are in entire agreement with Dr. E. R. FOTHERGILL, who in the course of the same debate asserted that some sort of coöperation is desirable with the lay press; for otherwise surely it is impossible to keep back information which is available on the reference shelf, or to avoid the portrait which is so easy to obtain without the victim's consent. It is idle to overlook the fact that in our impression of a personality not only is the name included, but the sound of the voice, the appearance of the features and gestures, and by laymen the withholding of everything but the name of the medical authority is regarded as a sort of professional snobbishness, difficult to understand, and apt to annoy. It may well be that we are passing through a temporary phase in regard to this form of advertisement, of which it is the newness that counts with the public, and that when the public becomes as used to it as it is to headlines and other developments or regressions in journalism, it will be able to assess the medical letter in the lay newspaper at its value. Perhaps more may be safely left to public opinion than those who are unduly anxious at the moment are inclined to admit.

Annotations.

"Ne quid nimis."

THE RESULTS OF TREATMENT IN SANATORIA.

THE results of hygienic-dietetic treatment as carried out in a well-run sanatorium are even more difficult to assess than those of any suggested specific remedy for pulmonary tuberculosis, for while the administration of a drug, the injection of a serum, or the inhalation of a gas can be tried out as the one variable factor in the general hygienic treatment of a community of invalids of approximately the same age and stage of disease, the sanatorium itself is essentially an institution where all the lessons derived from the sciences of pathology and hygiene, tempered by therapeutic experience, are combined and enforced. So universally approved is this basic routine of fresh air, rest, regulated diet, and exercise, that it is not easy to collect for purposes of comparison any body of individuals treated on radically different lines. Failing a control series of cases, the investigation undertaken at the request of the Medical Research Council by Sir Percival Horton-Smith Hartley, Dr. R. C. Wingfield, and Mr. J. H. R. Thompson, F.I.A., into the results of sanatorium treatment has taken the form of a careful study of the after-histories of those patients treated at the Brompton Hospital Sanatorium, Frimley, during the years 1905–14. The outcome of this study was issued last week in the form of a Green-book.[1]

The material under consideration consisted of 3400 patients, 2393 men and 1007 women, of whom only 10 per cent. defied all efforts to trace their present whereabouts or state of health. Incidentally, a survey of the occupation previously followed by these patients would at once suggest an open-air life as a desirable therapeutic measure, since the three largest groups in either sex were as follows: (Men) clerks, 399; shop assistants and salesmen, 158; porters (indoor), 98; (women) domestic servants, 216; housewives, 185; "at home," 118. The data on which the analysis was based is as shown in the table.

The mortality was determined according to condition on admission, according to condition on discharge, and again, according to the presence or absence of tubercle bacilli in the sputum; also in relation to the type of onset. Of the conclusions reached, the following are emphasised as of special importance. 1. The results of sanatorium treatment at Brompton Hospital correspond very closely with the results already reported from the King Edward VII. Sanatorium, Midhurst. They correspond, but not so closely, with those presented in Dr. H. Vallow's report from Bradford. 2. The mortality of patients without tubercle bacilli in the sputum is less than that of patients with tubercle bacilli in the sputum. The curves of survival among both males and females of those in the former category approximate to those of the general population. The authors deduce that enduring arrest of the disease is to be expected from sanatorium treatment in many early cases of the kind admitted to Frimley. 3. Of cases with tubercle bacilli in the sputum, it is certain that the earlier the stage when the disease comes under sanatorium treatment the greater is the chance of survival. In Group 1 (early cases) 79·3 of the male patients and 89·7 of the female survive five years, the corresponding number of survivors after ten years being 65·5 per cent. and 85·2 per cent. respectively.

Sex.	Number of patients.				Years of life observed.	
	Discharged	Died.	Lost sight of	Living in 1918.	Number.	Average number.
Males ..	2393	1207	209	977	11,446	4·8
Females .	1007	378	134	495	5,152	5·1

Those already convinced of the value of sanatorium treatment, to whom the problem centres on the relative stress to be laid on rest and graduated labour, will be interested in the similarity of the results obtained at Frimley to those recorded by other institutions. For the rest, the direct economic return from the sanatorium treatment of cases without tubercle bacilli in their sputum would seem to be established, inasmuch as the chance of survival in these cases does not differ widely from that of the non-tuberculous; again, the progress of very early "open" cases must be deemed satisfactory. More than half the total number of cases admitted to Frimley, however, belong to Group 2 (moderately advanced cases); among these the percentage of survivors after five years is 56·8 among males and 67·4 among female patients, and at the end of ten years, 38·2 males and 49·7 females. As to the patients admitted in a really advanced stage, it is not claimed that the results are at all satisfactory from the strictly economic standpoint. But this survey, which has been carried out with evident skill and impartiality, deliberately takes no account of the educative value of the sanatorium as one of the means whereby the spread of infection is minimised and a more correct mode of life is taught. It is impossible to estimate the far-reaching influence for good that may be exerted by sanatorium training on patients willing to learn how to protect their house-mates and neighbours, and it is probable that even if the duration of life of an advanced case discharged from a sanatorium is quite short, the habits inculcated there are likely to minimise the dangers of dissemination of tuberculosis among the general public.

A HOSPITAL SHIP IN THE PACIFIC.

Surgeon-Commander W. N. Horsfall has told, in the *Journal of the Royal Naval Medical Service*, how he fitted out and managed a hospital ship in the war: it is a story that is worth reading, while it cannot be said, whatever our hopes, that no one is ever likely to be in such a position again. The ship was *Glenlala*, No. 8, equipped at Sydney in August, 1914, for service with the Pacific Fleet. Her stores and equipment were ready for her, so she was able to sail in ten days. The sick-berth staff were ambulance brigade volun-

[1] Medical Research Council. Special Report Series No. 85. H.M. Stationery Office. 1924. 1s. 6d.

In many people, for example, the only left-handed activity appears in dealing cards, and from such an isolated action mancinism ranges in various forms through ambidexterity up to a complete inability to use the right hand for its ordinarily specialised functions. A definition, or even a standard, of mancinism is difficult to establish. The fact is sometimes overlooked that an action habitually performed by the left hand is difficult for the right, and the violinist who reversed the usual position of his instrument would find fingering with his right hand to be as difficult as bowing with his left. An interesting speculation is whether, if this reversed position had been conventionally correct, the left-hander would insist upon playing in what is now the orthodox one. This speculation arises from Dr. Inman's assumption that mancinism is a reaction of the whole personality, that it is psychologically determined and not due to an accidental disturbance in the localisation of nerve function. That it is the mark of a determined disposition finds scriptural confirmation, for the children of Benjamin valued highly the left-handed members of their fighting team, and the story of Ehud—"a man left-handed"—illustrates a fortunately rare degree of self-sufficiency and determination. The re-education of a left-hander in the ways of the herd involves the imposition upon him of the will of others, and we may find an explanation of the replacement of mancinism by a stammer in the view that the one is a protest that succeeds, whilst the other is an expostulation at its failure; the association of both in the same family may indicate temperamental modes of reacting to the same parental stimulus. We may note that psycho-analysts claim to trace stammer to the sense of guilt or fear arising from the Œdipus complex and to cure it by analysis, and many war stammers were removed by a superficial exploration of recent emotional episodes.

Unlike stammer or mancinism, squint is not easily imitated, but it *can* be imitated, and we must admit that it may be a personality reaction—that the child is doing it. Bacon noted that some can squint at will, and anticipated Dr. Inman when he wrote that "the cast of an eye is a gesture of aversion." Ophthalmologists as a whole are satisfied with the current explanation of squint, though the hypothetical "fusion centre" goes beyond what is demonstrable. It is difficult to conceive that the child can produce the symptom, even as an unconscious reaction; but the suggestion of a predominant emotional factor opens up such possibilities, not merely of clinical benefits but also of wider understanding of general principles, that Dr. Inman's evidence should be closely examined. His attempt to establish the relationship of the three conditions should be capable of statistical examination, but it is obvious that controls on a large scale are necessary. We must count the misses as well as the hits, a precaution too often not observed by that increasingly numerous body of writers who found their judgments on the comparison of figures. The psychologist may see something of value in intuitional judgments concerning these conditions. The parent or teacher tends to regard them as volitional and demands that the culprit should cease to offend, and this attitude, however bad its results, may depend upon a dim perception of the truth according to Dr. Inman. In regard to stammer his views will meet with little opposition, for they are already freely accepted; left-handedness is scarcely pathological, and whether its basis is anatomical or emotional is only of theoretical interest: but his attack upon the firmly entrenched position of his fellow ophthalmologists should stimulate further investigation of the temperamental reactions of the squinting child.

OBLIQUE ADVERTISING.

It was a piquant coincidence that the World's Advertising Convention visited Bradford on the actual day on which the Representative Body of the British Medical Association was discussing the question of procedures that might fall under the head of advertising by members of the medical profession. Advertising of a person differs essentially from advertising of a product, if only because a product is susceptible of analysis to prove the rightness of claims made for it, whereas a person cannot be cross-examined upon his fitness for any status that appears to be assumed publicly either by him or for him. We have been well reminded in the daily press that advertising is an art that applies only to products in bulk, and the Convention endeavoured, and with some success, to redeem the word from the discredit into which it has been brought as a synonym for trickery and dishonesty. The discussion by the Representative Body will be found on page 244 of this issue.

If we assume, in relation to what appears in the lay press, that in both trade advertisements and professional publicity the goods are honest, the essential difference remains between the repeated asseveration in the former case, that counts by its mere cumulative effect, and the public statement made upon a particular and topical subject by a medical man, which counts by reason of his established reputation. There are frequent situations in which the signed statement of a man of science, such as a medical man, is of the highest public value, and a very striking instance was afforded in the daily press last week apropos of a much-advertised remedy, in which the phrases "eminent chemist" or "eminent doctor" would obviously have counted for little or nothing—the actual names were needed, and it is the publication of names which offends the ideals of medical ethics. In this respect the otherwise admirable and practical report of the Association's Central Ethical Committee, which we print at length on page 246, was felt by the Representative Body to be out of touch with the actual situation. The newspapers, the report runs, can give the necessary assurance to their readers as to the professional standing of the authority quoted without mentioning names; but the meeting was quite definite in regarding as unreal the suggestion that names do not count. What professional opinion demands is rather that names shall only be used when they do count, and that there shall be some tribunal other than the authority himself or the organ of the press which claims him as an authority, to decide whether the name does count or not. Dr. R. L. Langdon-Down pointed out on behalf of the Ethical Committee that the basis of professional reputation must not be the self-praise of the individual nor the appreciation of those unqualified to judge, nor should it depend on the frequency of the appearance of the practitioner's name (with or without photograph) in the public press. The report of the Ethical Committee, he said, was an endeavour to clear their own minds and to treat the subject of advertising as a live part of "professional law," by which the speaker meant some accepted code of medical ethics. The principle is easy, only the application is difficult; and he held it to be the function of the British Medical Association to insist on the guiding factors, leaving to the General Medical in contrast to "racial" foreigners (or, indeed, to know whether by "national" he means "racial") and his reply to the proposition that there is no "instinctive" aversion to foreigners, a view set out well in Mr. J. H. Oldham's recent book, "Christianity and the Race Problem." But the book is, of course, small, and the author raises questions which would want an encyclopædia for adequate ventilation, so that what will appear to many to be cursory treatment is mostly a necessity of space and time, and sometimes, perhaps, a consequence of the author not having thought very hard on matters outside his immediate professional province. Generally, the book may irritate the progressive revolutionary, because it finds in biology grounds for defending the existing conservative order. And it will disappoint the visionary, because of its uncertain views about the future. If man imitates the numerous past evolutionary lines which have grown progressively longer and more complicated, he is evidently destined to come to an end altogether pretty soon. The share which chance takes in his ontogeny inclines Prof. Dendy, in another place, to the view that man is the sport of a Nature which is indifferent to his welfare. But he thinks that the world is big enough to accommodate the human race and he would have men choose their own wives—which are more cheerful thoughts.

There is a mistake (p. 62) about incompatibility of bloods for transfusion in man. The blood of a near relative is not much more likely to be suitable than that of a complete stranger: it depends on their precise genetic constitution in respect of isoagglutinins.

THROMBOPENIC ANÆMIA AND SPLENECTOMY.

THE fourth of the formed elements of the blood, the "platelet" or "thrombocyte," has laboured under a cloud in this country. Long ago it was pronounced to be an artefact or at best a fragment of the nuclear material of a dead and gone leucocyte, and as such it has been dismissed as unworthy of the serious contemplation either of the practising medical man or of the laboratory worker. In the years during which it has been regarded as a subject hardly suitable for conversation among polite British hæmatologists, however, it has been enjoying a large degree of attention abroad, particularly among the German and American workers, and the time now appears to have arrived when even in this country it must be admitted to a place in the blood picture. That the blood platelets undergo important alterations both in number and in appearance in at least one particular type of the hæmorrhagic diathesis was pointed out ten years ago by Duke[1] in America, and a little later by Frank[2] in Germany. Frank from Berlin, and Kaznelson[3] from Prague, both described a syndrome characterised by purpura hæmorrhagica in association with splenomegaly. In this condition they found the blood invariably to show a severe anæmia of aplastic type, together with a great reduction in the number of the platelets; usually there was also a leucopenia, sometimes extreme in degree, with its main incidence upon the granular leucocytes. Both Frank and Kaznelson regarded the reduction of the platelets as the immediate cause of the purpuric manifestations; for this condition Frank used the term "thrombopenia," which has come into more or less general use, though the term "thrombocytopenia," suggested by Kaznelson, is preferable, if not on the grounds of euphony, at least as an accurate statement of the state of affairs which it is intended to indicate. Three cases of this thrombopenic anæmia, all showing purpura and splenomegaly, were recently reported by S. C. Dyke[4] in THE LANCET; in Dyke's cases infection of the hæmatopoietic system was found post mortem in every case, but this was regarded by the author as secondary to the weakened state of this tissue. Both Frank and Kaznelson, though on different grounds, implicated the spleen through a disorder in its function as the cause of the condition. Frank regarded the thrombopenia as due to an aplastic state of the bone-marrow, the source of the platelets, and this myelophthisic condition he thought to be brought about by some toxic body produced in the spleen and acting through the blood-stream. Kaznelson found the enlarged spleen from one of his cases to be crammed with platelets, and on the strength of this observation concluded that the diminution of these bodies was due to their abnormal destruction by the spleen. Both Kaznelson and Frank recommended splenectomy for this condition, and practised it with apparently beneficial results.

In the last published volume of the International Clinics, N. E. Brill,[5] of New York, records one further case of splenectomy for purpura hæmorrhagica, and demonstrates a second case in which operation had not been undertaken at the time of reporting; in this second case the spleen was also removed later, and the results of both operations have since been described together by the same author.[6] In both cases splenectomy resulted in the immediate cessation of the hæmorrhages, which had been severe and long-continued, and in the apparent restoration of the patients to complete health. So sudden was the cessation of the hæmorrhages in his cases that Brill was inclined to doubt whether the purpuric manifestations could be entirely accounted for by the existing thrombopenia. He found that, although the platelet count rose immediately after the splenectomy, it fell within a week almost to its previous low level, and concluded that some factor other than mere reduction in the number of the platelets must be present to produce purpura; this factor, he suggested, might be some unknown substance produced by the spleen and acting through the blood-stream. His views are thus seen to partake of those of both Frank and Kaznelson. Probably the end of the matter is not yet, but very strong evidence in support of the view of Kaznelson was produced by S. P. Bedson at the meeting of the Pathological Association of Great Britain and Ireland, held in London a few days ago. Carrying on the previous observations of J. C. G. Ledingham[7] this worker was able some time ago, by the use of an antiplatelet serum prepared from rabbits by the injection of guinea-pig platelets, to show that destruction of the platelets in the guinea-pig was always followed by purpura.[8] At the meeting in question he showed four guinea-pigs, two of which had undergone splenectomy, and all of which had received the same dose of antiplatelet serum. The unsplenectomised animals showed an intense purpura; those from which the spleen had been removed, on the other hand, showed no hæmorrhagic manifestations. Bedson offered as an explanation of this phenomenon the fact observed by himself that after splenectomy the platelets greatly increase in numbers, as a result, he suggests, of the removal of the normal thrombocytolytic action of the spleen. He found that this increase of platelets in the guinea-pig after splenectomy was only temporary, and that as other portions of the reticulo-endothelial system took on the function of dealing with the thrombocytes, their numbers again fell to normal. On this supposition the benefit to be expected from splenectomy in purpura hæmorrhagica should be only temporary; whether this will prove to be the case remains to be seen. Already the operation has been performed at least twice in this country for this condition and reports may be expected in due course.

teers, who, though with little previous experience, did capital work, especially when they had unlearnt their first impression that they were working as a favour, and did not have to do as they were told. Commander Horsfall, who had been a staff surgeon in the Navy, seems to have concentrated on essentials, and generally managed to see that they were got. The six medical officers under him were sent on board in plain clothes and the volunteers did not acknowledge their authority, which made things awkward, but Commander Horsfall, with the help of the nursing sisters, made them shoulder straps, "when the surgeons became commissioned officers," and all went well. He adds: "The Navy is a great service and its discipline is such as to give to one the greatest freedom." It will be easier to fit out a hospital ship in future, whether the action has to be taken in routine or under emergency, and those who want to know what to do and how to do it should consult Surgeon Rear-Admiral Sutton's book on the subject. But personality will always find outlets. No book instruction will help a man much during a strike of the firemen in their forecastle, nor can a written recipe be given for Commander Horsfall's arguments when he persuaded them to call the strike off and let the ship go to sea.

We notice a curious misprint in this issue of the journal. The well-known Parkes Memorial Prize does not commemorate the distinguished R.A.M.C. officer Surgeon Parke, who crossed Africa with Stanley and won high appreciation for his care of the sick; but was founded in honour of the famous E. A. Parkes, the father of modern military hygiene and first professor of hygiene in the Army Medical School.

THE SUBNORMAL EX-SOLDIER.

ALTHOUGH it is now over five years since the armistice was signed, the time has not yet been reached when the care of the man who came back broken from the war can be relaxed. Lord Haig points this out in an introduction to the fifth annual report of the Enham Village Centre, adding that at this centre the outlook of many disabled ex-Service men has again become happy and contented after years of hopelessness and uncertainty. It has always been one object of this Centre, the policy of which was conceived and has largely been directed by medical men, to establish a permanent settlement for those men who, owing to the nature of their disability, are considered unfit for re-entering the labour market. Fifty disabled men are now permanently employed or settled at Enham, 30 of them occupying cottages, and a wood-working factory has been erected, fitted with up-to-date machinery, and capable of employing 100–125 men. The population of the Centre has, indeed, risen from the original number of 62 to the present large total of 468, all told. At the same time, during the last 15 months, a scheme has been developed under the Ministry of Labour to include industrial training for those able to do 44 hours' training per week. The actual number of these, naturally, is now diminishing from year to year, as there become fewer cases eligible for combined treatment and training, but it is the ambition of the promoters that as the supply of war victims falls, the Centre may remain as a national establishment for the restoration of health and for the physical re-education of other persons injured in the service of the State. Dr. G. V. Stockdale, medical officer to the Centre, tells us that of the 103 cases remaining in residence on the first day of the present year, 46 were suffering from neurasthenia, 35 from general surgical conditions, half of them being gunshot wounds of the head, 19 from general medical conditions, three from the results of tropical diseases, the proportion being practically the same as last year. Pensioners who, by reason of their disability, can never become employable or work for themselves, should, Dr. Stockdale feels sure, be allowed to live at home on an adequate pension; but for those who would find difficulty in getting employment outside, the system adopted at Enham appears to offer the most satisfactory solution of the disabled ex-Service man's problem. Employment is here offered under sheltered conditions; the man is freed from anxiety and encouraged by a feeling of comparative independence. Of the 622 men who had left the Centre up to the time of the report, 348 were reported as employed and in training, 52 as unemployable (80–100 per cent. pensions), and 33 as unemployed. Every effort is being made to find work for these men, for all of whom references can be given. The chief wants of the Centre are now more cottages, an outlet for articles produced in the new workshops, and an endowment fund of £100,000 to supplement the work of men suffering from severe disablement who can never become economic productive units. The economic position of the Centre is not yet what it should be, and there are difficulties to be met, but the report is a record of a successful and well-administered piece of practical philanthropy.

BIOLOGY AND SOCIOLOGY.

Prof. Arthur Dendy[1] believes that the general principles of biology can help us to solve the various social and political problems which bother us to-day. With his primary postulates not everyone will agree, and it is well that he has set them out plainly. The pyramid of society is based, he says, on what took place in the world of living things before mankind came into existence. It may be so. But there is a not unimportant school that thinks it more likely that man's soul is qualitatively a new thing, added to the accumulation of evolved attributes and not necessarily arising from them. On the other hand, it has also been urged that the dead and live worlds form one continuous whole with qualities differing quantitatively rather than qualitatively in its diverse parts. Prof. Dendy premises, too, that the laws which governed organic evolution in its earlier stages were not repealed when man arrived on the scene. They may not have been repealed, it is true, but some people think that they have been added to to such an extent that, like a good many old laws, they no longer run. With these possible divergencies of outlook at the very beginning, anyone who believes that progress for the future may be obtained by a study of the past will read the book with interest. It is intended more especially for those without any special knowledge of biology: there is much more biology than political economy and the biological exposition is of the high order that we should expect from the author of the "Outlines of Evolutionary Biology." The sociological conclusions are put shortly and dogmatically, the position of women, the House of Lords, birth-control, democracy, the colour question, and so on, are disposed of summarily enough. Broadly speaking, four main biological topics are dealt with. The fact of organic evolution shows that man is an animal in series with other animals. The study of the community of organs which makes up the individual and of the integration of individuals to make insect and similar societies points the way to the arrangements which are desirable in human communities. The inherent variability of live things indicates that the idea of the essential equality of all men is delusory or worse. The facts of heredity and modern knowledge of its mechanism are of prime constructive importance: "it is better to be born with the right kind of chromosomes than with a silver spoon in one's mouth." Such, with many subsections, is the main argument. We could wish that parts of it had been set out in greater detail. Prof. Dendy mentions, for example (p. 63), "the instinctive aversion to foreigners which lies at the root of national feeling." It would have been interesting to hear his discussion of "national" dealt with is ruptures of the sclera. Those caused by slowly moving objects. such as stones or fists striking the eye-ball directly. occur in the equator where the eye is least supported. On the other hand, rapidly moving missiles which pass through the orbit, but do not strike the eye directly, may yet cause a rupture of the side opposite to the point of impact of the air-wave caused by the missile—i.e., at the point of contre-coup. Concussion changes of the iris and ciliary body include irido-dialysis—i.e., the tearing away of a portion of the iris from its peripheral attachment, and dislocation of the iris peripherally causing a pear-shaped pupil, or in severe cases an "apparent iridectomy." Concussion changes in the retina and choroid occur in three situations: (1) the area adjacent to the site of impact; (2) the macular region: and (3) opposite the site of impact. The first situation is the most constant, so that in cases where the entrance wound is insignificant the ophthalmoscope may give the first proof that a foreign body has traversed the orbit. Histologically hæmorrhages in and about the retina and choroid are of every variety, subhyaloid, inter-retinal, and subchoroidal. The four main changes found in the retina are (1) the shrinking and disappearance of the nuclei of the granular layers, (2) vacuolation of its substance, (3) the splitting of the retina into layers by hæmorrhages, and (4) folding of the retina. Evulsion of the optic nerve may also be a concussion phenomenon—i.e., without any penetrating wound. A blow on the front of the eye may so increase the intra-ocular pressure as to break through the lamina cribrosa and expel the nerve. The lamina cribrosa may also be ruptured by the explosive effect of a missile passing through the back of the orbit or by extreme rotation of the eye. In either case the optic nerve will be extremely stretched and evulsion of the nerve head may occur. This article and the plates that accompany it should be studied in the original.

WET BERI-BERI IN FRENCH COLONIAL TROOPS.

Major J. M. Fricker describes, in a recent number of the *Archives de Médecine Militaires*, a small outbreak of wet beri-beri which arose in France among some Hovas from Madagascar. In June, 1923, several of these men were placed upon the sick list, their most conspicuous symptom in all cases being an œdema which was very marked in the face and lower limbs. Several of the patients died, and with a view to special laboratory investigation all of the remaining cases were gathered into a hospital at Châlons, where they came under the care of Major Fricker. Fifteen in all of these special cases were received. The most striking evidence of disease was the facial œdema, with puffiness of both eyelids, and, in the three worst cases, a full moon-like appearance, noticeable because the Hovas have very well-cut features. Those lightly attacked had œdema of the legs: in the three severe cases the œdema had gradually appeared higher and higher, invading thighs, hips, scrotum, penis, abdomen, and trunk, so the vertebral spines could not be felt. Each gave a history of 20 or 30 days of slowly increasing swelling of the legs. They were all easily fatigued and complained of breathlessness and pains in the legs. Examination showed but one positive further sign, oliguria; no pyrexia, no albuminuria, no casts, no heart lesions, no pareses or anæsthesiæ, but the three advanced cases manifested ascites, pulmonary œdema (with cough), pleural effusion (no fibrin in the fluid drawn off), and pericardial effusion: they had also orthopnœa. None had ankylostomiasis, so the diagnosis made was the wet form of beri-beri. All had been a year in France, and had been getting a diet of rice and meat, but with too few green vegetables. They were put on lightly boiled eggs, plenty of green vegetables, salads, lemons, and beer yeast, and the slight cases had recovered in ten days. The more serious got, in addition, theobromine as a diuretic, cardiac tonics, a salt-free diet, and little to drink; they soon began to pass more urine, their œdema passed off, and they were well in three weeks.

THE VIRUS OF FOOT-AND-MOUTH DISEASE.

THE *Berliner Tieraerztliche Wochenschrift* of July 4th contains a set of reproductions of ultra-microphotographs of foot-and-mouth disease cultures, some of which we reproduce here. Fig. 1 shows a superficial deposit of a culture on a solid medium, with many colonies under a magnification of 375; they take the form of small elevations the size of a red blood cell. Fig. 2 shows the same colonies photographed with spectral blue light under a magnification of 1200. Fig. 3 shows the same colonies photographed with Köhler's ultra-micro-photo apparatus, with ultra-violet cadmium light (×2000). Fig. 4 shows a smear preparation photographed with ultra-violet light. These interesting photographs give a good idea of the appearances of the colonies, which be it remembered, are themselves scarcely larger than a single yeast cell.

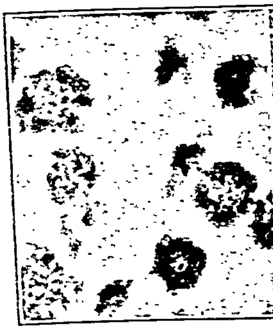

FIG. 4.

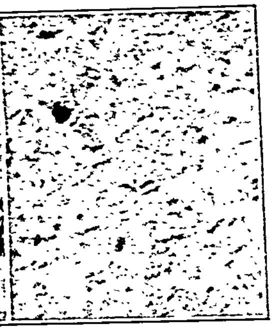

Sir Harold J. Stiles, K.B.E., has been appointed by the King an honorary surgeon to His Majesty in Scotland, in the place of the late Sir William Macewen.

Dr. E. H. Kettle, who has held since 1919 the post of pathologist to St. Mary's Hospital, London, and lecturer in pathology at the medical school, has been appointed to the chair of Pathology and Bacteriology in the Welsh National School of Medicine, vacant by the death of Prof. Emrys-Roberts.

THE Royal Commission on National Health Insurance announce that they will commence to hold meetings for the hearing of evidence in October next. Any persons or bodies desiring to give evidence should in the first instance communicate in writing with the Secretary of the Commission, Mr. E. Hackforth, at the Ministry of Health, Whitehall, S.W. 1, stating the main heads of the evidence they desire to submit.

THE HEALTH OF THE MERCHANT SEAMAN.

IN the course of a discussion on ship sanitation at the Royal Sanitary Institute congress at Liverpool, which was reported in our last week's issue, a plea for the collection of statistics of death in the Merchant Marine was put forward by Fleet-Surgeon W. E. Home. Commenting on papers on the Present Standard of Ship Sanitation and on the Hygiene of the Tramp Steamer, communicated respectively by Dr. W. Hanna and Dr. J. Howard Jones, he pointed out that these two excellent papers on hygiene made no allusion to statistics of illness or deaths in the Merchant Marine, and that, in fact, no useful health statistics were published as to this service. The Army, Navy, and Air Force had organised medical services to watch and report on their health. For the rest of the people of England, except the Merchant Marine, the Ministry of Health was responsible. Nobody was responsible for the health of the merchant seamen. All that could be ascertained about his health or his diseases was in the Return of Deaths on Vessels, issued by the Board of Trade, which was an unsatisfactory report. It contained lists of the deaths that occurred in 1921 among British seamen, foreign seamen, and Lascars, but the total figure (274,216) was not differentiated among these groups. If the proportions were the same as in 1914, the several numbers would be (in thousands) British, 190; foreign, 33; Lascars, 50. The speaker had been unable to find that the head-quarter staff of the Board of Trade contained any doctors. Tuberculosis was classified under "Group B, Constitutional," the Board of Trade not having yet heard, apparently, that tuberculosis is known now to be infectious. A classification which linked tubercle, rheumatism, and cancer in one group was once in vogue in the Navy, but was given up by the Admiralty in the Navy Health Blue-book as long ago as 1886. Fleet-Surgeon Home quoted other anomalies of classification and submitted two resolutions begging the Council of the Institute to ask that at least better returns be provided in future, but that, if possible, the care of the health of merchant seamen should be handed over to the Ministry of Health and taken altogether away from the Board of Trade. This was seconded by Alderman Askew, chairman of the Hull and Goole Port Sanitary Authority, and carried unanimously.

EXANTHEMA SUBITUM.

THE occurrence of rashes associated with fever in infancy and early childhood has been widely recognised, and has usually been attributed to digestive disturbances. While these rashes are of no serious import to the patient they are often a source of perplexity to the practitioner, owing to their resemblance to the infectious exanthemata, more particularly to rubella. During the last decade a number of continental and American pædiatrists have described cases of fever, lasting a few days, and followed by an exanthem, but showing no evidence of infectivity. Dr. E. Glanzmann, of Berne,[1] reviews the literature of this subject, and describes a number of cases which he has observed during the last six years. He is of the opinion that cases of remittent fever lasting three days, falling by crisis, and followed a few hours later by an exanthem, are sufficiently numerous and true to type to justify their description as a clinical entity, for which he has retained the name of *Exanthema subitum*, which was suggested by B. S. Veeder and J. Hempelmann in 1921. The rash, usually morbilliform but occasionally erythematous, is most copious on the trunk, and scanty or absent on the face and limbs, it disappears in from 24 to 48 hours. The blood-picture is sufficiently constant to be of diagnostic value, showing marked leucopenia with a relative lymphocytosis. Dr. Glanzmann discusses in detail the points by which this syndrome may be distinguished from the other exanthemata. The authors whose articles are noticed in this paper are not in complete agreement about the nature of this condition. Dr. Levy regarded it as an atypical form of rubella; in some of his cases the cervical glands were enlarged. One point of interest which is not mentioned might emerge from the after-history; how many of these cases subsequently contract rubella?

CONGENITAL ENLARGEMENT OF THE COLON.

AT a recent meeting of the Medical Society of the Hospitals of Paris, Drs. Bergé, Chevrier, and Lefèvre demonstrated post mortem a case of congenital enlargement of the colon in a boy of 15. The patient had suffered from constipation since birth, and had often felt no call to stool for periods of a week or even a month at a time. He was operated upon for an attack of intestinal obstruction, and died a few days later. At the autopsy it was found that not only the abdomen but the thorax also were completely filled by two loops of the colon, one of which was distended to an enormous extent. At first sight it seemed as though the thoraco-abdominal cavity, from clavicles to pubis, contained nothing but these two enormous loops of colon, but closer examination revealed a narrow space, about 2 inches in depth, in the upper part of the thorax, into which the heart, the lungs, and the liver were compressed. The spleen alone retained approximately its normal position. (See figure.) The loop of distended colon measured 50 cm. in length, 27 cm. in breadth, and 51 cm. in circumference. The retained fæcal matter weighed almost 14 kg., and the loop contained much gas. "This weight and these dimensions," says a French correspondent, "justify the publication of this case and diagram."

Congenital enlargement of the colon.

CONCUSSION CHANGES IN THE EYE.

IN the current number of the *British Journal of Ophthalmology* Sir William Lister discusses some concussion changes met with in military practice. The main part of the paper now published was read at a meeting of the American Academy of Ophthalmology and Oto-laryngology at Washington in 1923; it is liberally illustrated by coloured plates of fundi and many figures and diagrams. The first subject

amœbic infection exist side by side, and in such an event a course of treatment with emetine is of primary importance. Wasting is often a marked feature of chronic dysentery, and may be so extreme that the nourishment of the patient becomes the paramount consideration. Under these circumstances better results may be hoped for if the patient is placed on a fairly generous dietary, composed of soft semi-solid articles of food, from which everything of an irritating nature is rigidly excluded, than on a strictly fluid régime. In the management of the bowels constipation may call for the use of sulphates, or in some cases repeated small doses of calomel (gr. ¼ four times in the day) may be remarkably beneficial. In other cases profuse and exhausting diarrhœa is a prominent feature, and may be met by β-naphthol (gr. 5 in cachet four times a day), or bismuth salicylate (gr. 20 four times a day). Lavage of the intestine is more often useful than in acute dysentery; a long soft tube should be employed, and the fluid allowed to flow in gently through a funnel by gravitation. Dilute solutions of antiseptics, such as eusol, or of astringents, such as silver nitrate or copper sulphate (1 in 1000), may be used, but it may be regarded as doubtful whether these have any real advantage over cleansing injections of warm boric or weak permanganate solutions, or even of warm saline. A considerable number of cases ultimately prove refractory to all forms of medical treatment, and in these the question of securing a more efficient degree of lavage by appendicostomy should be considered, or complete rest for the lower bowel may be temporarily provided by arranging for the evacuation of the fæces through an opening in the cæcum. Vaccine treatment has been employed with a certain measure of success. Perforation is a more likely complication of chronic than of acute dysentery; owing to adhesions the resulting peritonitis is often localised, and ultimately a large circumscribed abscess may be formed. On account of the chronic nature of the process the clinical picture is often quite indefinite, and the condition may exist for some time before it is recognised; the treatment is surgical.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE Prince of Wales presided at a special meeting of the President and General Council of King Edward's Hospital Fund for London at St. James's Palace on July 25th.

Lord Stuart of Wortley, chairman of the Management Committee, presented a report on the recommendations of the Ambulance Cases Disposal Committee dealing with the need for additional voluntary hospital accommodation, the inquiry now being conducted by the Voluntary Hospitals Commission; and the bequests of the late Mr. and Mrs. Wells.

Recommendations of the Ambulance Cases Disposal Committee.

The Management Committee asked the views of the Distribution Committee on the recommendation—

> That King Edward's Hospital Fund, in making its annual grants, should take into consideration whether hospitals which deal with cases of accident or sudden illness occurring in streets or public places provide (*a*) a reasonably sufficient number of beds for such cases, (*b*) a reasonably sufficient number of observation beds or beds attached to the casualty department, in order to avoid, as far as possible, transfer to another institution of any patient whose condition might be likely to be prejudiced by such transfer.

The Distribution Committee have expressed their willingness to carry out this recommendation and have asked the hospitals for particulars of their available bed accommodation under these heads, and for their views as to its adequacy. The Ambulance Cases Disposal Committee, in their report, referred to the fact that most of the cases of alleged unnecessary or injurious transfer of patients had been reported from Lambeth. They associated this fact with the general shortage of voluntary hospital beds in South London, where King's College Hospital has only been able, since the war, to keep open 226 beds for ordinary patients out of 388 provided in 1913 for the specific purpose of reducing that shortage. The opinion expressed by the Ambulance Cases Disposal Committee in March was strengthened in April by the occurrence of two further cases of transfer from King's College Hospital for want of beds. The Distribution Committee are accordingly paying special attention to the question of the supply of beds for accident cases in South London, and particularly at King's College Hospital. The Management Committee invited the observations of the police and ambulance authorities on the recommendation—

> (*a*) That it be represented to the police and ambulance authorities that no institution which is not equipped for the reception and treatment of serious cases of accident or illness should be retained on the list of institutions to which ambulance cases should in the first instance be taken.
>
> (*b*) That it be suggested to the authorities that in drawing up the list of such institutions the coöperation of the Ministry of Health be sought in the case of infirmaries, and of King Edward's Hospital Fund in the case of hospitals.

It will be noticed that this recommendation deals primarily with the provision of emergency treatment in the first instance, as distinct from the provision of beds, which is dealt with in the previous recommendation. The London County Council has concurred in both parts of the latter recommendation and has given directions for them to be carried into effect by the London Ambulance Service.

The Management Committee also considered a recommendation—

> That it be represented to the Ministry of Health that in the case of street accidents or sudden illness brought to the casualty department of a voluntary hospital (including "removals" from Poor-law institutions): (*a*) no question of residence of the patient, or site of the accident, or site of the transferring hospital, should be raised prior to reception and treatment; (*b*) no such cases should be transferred to another institution if their condition might be likely to be prejudiced by such transfer; (*c*) the charge for treatment of such cases should be a common metropolitan one, and not fall on the union receiving and treating such patients; (*d*) such patients should not be subject to any disability arising out of technical pauperisation as the result of their reception and treatment.

These changes would remove certain difficulties which now sometimes prevent an accident case from being taken to the infirmary which lies nearest.

The Management Committee addressed a letter to the Ministry of Health, urging upon his consideration their view that these proposals should be the subject of early legislation or administrative action. In doing so, they drew the Minister's attention to a resolution passed on May 29th by a conference of representatives of Metropolitan Poor-law Boards of Guardians, endorsing generally the conclusions and recommendations of the Ambulance Cases Disposal Committee.

Need for Additional Voluntary Hospital Accommodation and the Inquiry by the Voluntary Hospitals Commission.

The Voluntary Hospitals Commission have been asked by the Minister of Health to make an inquiry into the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it. The Commission have requested the King's Fund, as Voluntary Hospitals Committee for London, to issue a questionnaire to the hospitals of London, and to transmit the replies to the Commission with a general covering report. The report will be prepared by the Management Committee with the assistance of the Distribution and Hospital Economy Committees. It was already known to the King's Fund that numerous

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXII.—THE TREATMENT OF DYSENTERY.

I.—Bacillary Dysentery.[1]

(A) *Acute Bacillary Dysentery.*

A patient suffering from an acute attack of bacillary dysentery should be put to bed and not allowed to get up for any purpose. The treatment may be conveniently discussed under three headings: (1) diet, (2) the administration of salines, (3) serum treatment.

The *diet* should be fluid, consisting of albumin water, whey, beef-tea, chicken-tea, raw beef-juice, or meat jelly, given in small quantities every two hours. Milk is unsuitable in the acute stage of dysentery, and should be excluded from the dietary. During the first few days the supply of an abundant amount of fluid is of great importance, and the patient should be encouraged to drink as much water, barley-water, or lemonade (only slightly sweetened) as he may desire.

The *administration of salines* is invaluable during this stage. Their action, in no sense specific, depends on a gentle lavage of the intestinal mucous membrane by the copious watery secretions, whereby inflammatory products containing bacilli and toxins are washed away in place of being absorbed. The sulphate of magnesium or sodium, or sodium phosphate may be given, a drachm every two hours during the daytime only, between the hours of 8 A.M. and 6 P.M. Diurnal irrigation of this kind may be safely combined with sedative treatment at night time—e.g., a dose of laudanum or a hypodermic injection of morphia, often needed for the relief of pain and tenesmus, and to promote sleep. After two or three days the quantity of sulphate may be reduced by one half; but the treatment in modified form should be continued until convalescence is established, as it is important that the motions should be prevented from becoming hard and constipated during this perod.

Serum Treatment.—Antidysenteric serum is of the greatest value, and should be given in all but mild cases. Two conditions are essential to success: (*a*) the serum should be administered at the earliest moment; (*b*) it should be given in sufficient quantity. The earlier the stage of the disease, the more effective is the treatment. Its value rapidly lessens with lapse of time, and there is probably little to be gained by initiating serum treatment at a later period than the sixth day. 60, 80, or 100 c.cm. may be injected subcutaneously into the loose tissues of the lateral abdominal wall or elsewhere; the effects of smaller doses are in proportion far less striking. In many instances a single dose is all that is necessary; but if the symptoms are not clearing satisfactorily a second dose may be given after an interval of two days. In urgent cases with fulminating symptoms of choleraic type the serum should be injected intravenously and combined with hypertonic saline solution. The most favourable results may be expected if a serum is used containing exclusively Shiga or Flexner antibodies, according to the type of infection; but in practice no time should be lost by waiting for the laboratory report; the more acute the symptoms, the more likely is the case to be one of Shiga infection, and the best course is to use a polyvalent serum which is known to be rich in Shiga elements. If a second dose is needed, it may consist of pure anti-Shiga or anti-Flexner serum, according to the pathological diagnosis.

The drawbacks to serum treatment are for the most part unimportant. Anaphylaxis is a very rare complication, but its manifestations may be so formidable that it is a wise practice to put the following preliminary questions to the patient: (*a*) Has he had diphtheria? (*b*) Was he on active service during the war? If so, (*c*) Was he wounded; or (*d*) did he suffer from dysentery? In the case of an affirmative answer to any of these queries, the administration of the full dose of serum should be preceded by a tentative injection of 1 c.cm., which will have the effect of unmasking and, at the same time, of removing any hyper-sensitivism that may exist. Serum fever, arising about the fifth day after the injection, with an urticarial or erythematous type of rash, is of no serious consequence. Joint pains, with or without swelling, may occur at the same time or a few days later, and have to be distinguished from true dysenteric arthritis, which, however, is a much more definite and severe form of arthritis, and is comparatively late in its onset.

Convalescence.—The most important consideration in guiding the patient through the stage of convalescence is the management of the diet. This should be increased, as in typhoid fever, by slow degrees, the effect of each addition being carefully watched before any further advance is permitted. Nutritious jellies, egg beaten up in milk, custard, junket, soft bread and milk made without crusts, and milk thickened with farinaceous foods may successively be added. When convalescence is fully established, as shown by a clean tongue and the disappearance of abdominal symptoms, a rapid advance to a normal dietary may with confidence be made; even in cases where the initial symptoms were severe, the progress to recovery may, in the absence of complications, often be surprisingly rapid.

Complications.—Profuse hæmorrhage and perforation are both rare events in the course of the acute stage of dysentery. Hæmorrhage calls for absolute rest, the complete withholding of nourishment by the mouth, and the administration of morphia hypodermically. In severe cases the subcutaneous injection of normal saline, or an isotonic mixture of glucose solution with saline is indicated. In the event of small recurring hæmorrhages rectal injections of copper sulphate, 1 in 1000, may be useful, the mucous membrane having been cleansed by preliminary irrigation with warm water or saline solution. In the unlikely event of perforation during the acute stage an immediate laparotomy affords the only chance of saving the patient's life. In cases of fulminating dysentery with diarrhœa of choleraic type it is important to exclude cholera, which may be done by a microscopic examination of the watery stools and noting the absence of vibrios; the treatment consists of the immediate injection intravenously of a full dose of serum, repeated if necessary, and combined with hypertonic saline solution. Arthritis occurs more often in sequel to a Shiga infection than in cases of Flexner dysentery. It arises usually in the course of the third week, and is accompanied by considerable enlargement and tenderness of the joints, with effusion of fluid. Complete rest of the affected joints is necessary, and much relief may be obtained in suitable cases by tapping and the removal of the fluid. A dose or two of serum may be followed by rapid subsidence of the joint symptoms; but this remedy should be used with caution if serum has been administered during the acute stage, owing to the risk of anaphylaxis. It is a mistake to keep the joints at rest too long; after the subsidence of the acute symptoms, massage and carefully regulated passive movements should be employed, and radiant heat is useful.

(B) *Chronic Bacillary Dysentery.*

Chronic bacillary dysentery is more likely to follow in the course of a comparatively mild Flexner infection than the severer types of Shiga dysentery, and may lead to a clinical condition that calls for the utmost skill and resourcefulness on the part of the physician. As the symptoms of a *chronic bacillary* infection may closely resemble those of amœbic dysentery, it is necessary as a preliminary measure to make a careful examination of the stools. In not a few cases it will be found that both a bacillary and an

amœbic infection exist side by side, and in such an event a course of treatment with emetine is of primary importance. Wasting is often a marked feature of chronic dysentery, and may be so extreme that the nourishment of the patient becomes the paramount consideration. Under these circumstances better results may be hoped for if the patient is placed on a fairly generous dietary, composed of soft semi-solid articles of food, from which everything of an irritating nature is rigidly excluded, than on a strictly fluid régime. In the management of the bowels constipation may call for the use of sulphates, or in some cases repeated small doses of calomel (gr. ¼ four times in the day) may be remarkably beneficial. In other cases profuse and exhausting diarrhœa is a prominent feature, and may be met by β-naphthol (gr. 5 in cachet four times a day), or bismuth salicylate (gr. 20 four times a day). Lavage of the intestine is more often useful than in acute dysentery; a long soft tube should be employed, and the fluid allowed to flow in gently through a funnel by gravitation. Dilute solutions of antiseptics, such as eusol, or of astringents, such as silver nitrate or copper sulphate (1 in 1000), may be used, but it may be regarded as doubtful whether these have any real advantage over cleansing injections of warm boric or weak permanganate solutions, or even of warm saline. A considerable number of cases ultimately prove refractory to all forms of medical treatment, and in these the question of securing a more efficient degree of lavage by appendicostomy should be considered, or complete rest for the lower bowel may be temporarily provided by arranging for the evacuation of the fæces through an opening in the cæcum. Vaccine treatment has been employed with a certain measure of success. Perforation is a more likely complication of chronic than of acute dysentery; owing to adhesions the resulting peritonitis is often localised, and ultimately a large circumscribed abscess may be formed. On account of the chronic nature of the process the clinical picture is often quite indefinite, and the condition may exist for some time before it is recognised; the treatment is surgical.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE Prince of Wales presided at a special meeting of the President and General Council of King Edward's Hospital Fund for London at St. James's Palace on July 25th.

Lord Stuart of Wortley, chairman of the Management Committee, presented a report on the recommendations of the Ambulance Cases Disposal Committee dealing with the need for additional voluntary hospital accommodation, the inquiry now being conducted by the Voluntary Hospitals Commission; and the bequests of the late Mr. and Mrs. Wells.

Recommendations of the Ambulance Cases Disposal Committee.

The Management Committee asked the views of the Distribution Committee on the recommendation—

That King Edward's Hospital Fund, in making its annual grants, should take into consideration whether hospitals which deal with cases of accident or sudden illness occurring in streets or public places provide (*a*) a reasonably sufficient number of beds for such cases, (*b*) a reasonably sufficient number of observation beds or beds attached to the casualty department, in order to avoid, as far as possible, transfer to another institution of any patient whose condition might be likely to be prejudiced by such transfer.

The Distribution Committee have expressed their willingness to carry out this recommendation and have asked the hospitals for particulars of their available bed accommodation under these heads, and for their views as to its adequacy. The Ambulance Cases Disposal Committee, in their report, referred to the fact that most of the cases of alleged unnecessary or injurious transfer of patients had been reported from Lambeth. They associated this fact with the general shortage of voluntary hospital beds in South London, where King's College Hospital has only been able, since the war, to keep open 226 beds for ordinary patients out of 388 provided in 1913 for the specific purpose of reducing that shortage. The opinion expressed by the Ambulance Cases Disposal Committee in March was strengthened in April by the occurrence of two further cases of transfer from King's College Hospital for want of beds. The Distribution Committee are accordingly paying special attention to the question of the supply of beds for accident cases in South London, and particularly at King's College Hospital. The Management Committee invited the observations of the police and ambulance authorities on the recommendation—

(*a*) That it be represented to the police and ambulance authorities that no institution which is not equipped for the reception and treatment of serious cases of accident or illness should be retained on the list of institutions to which ambulance cases should in the first instance be taken.

(*b*) That it be suggested to the authorities that in drawing up the list of such institutions the coöperation of the Ministry of Health be sought in the case of infirmaries, and of King Edward's Hospital Fund in the case of hospitals.

It will be noticed that this recommendation deals primarily with the provision of emergency treatment in the first instance, as distinct from the provision of beds, which is dealt with in the previous recommendation. The London County Council has concurred in both parts of the latter recommendation and has given directions for them to be carried into effect by the London Ambulance Service.

The Management Committee also considered a recommendation—

That it be represented to the Ministry of Health *that* in the case of street accidents or sudden illness brought to Poor-law institutions (including "removals" from the casualty department of a voluntary hospital): (*a*) no question of residence of the patient, or site of the accident, or site of the transferring hospital, should be raised prior to reception and treatment; (*b*) no such cases should be transferred to another institution if their condition might be likely to be prejudiced by such transfer; (*c*) the charge for treatment of such cases should be a common metropolitan one, and not fall on the union receiving and treating such patients; (*d*) such patients should not be subject to any disability arising out of technical pauperisation as the result of their reception and treatment.

These changes would remove certain difficulties which now sometimes prevent an accident case from being taken to the infirmary which lies nearest.

The Management Committee addressed a letter to the Ministry of Health, urging upon his consideration their view that these proposals should be the subject of early legislation or administrative action. In doing so, they drew the Minister's attention to a resolution passed on May 29th by a conference of representatives of Metropolitan Poor-law Boards of Guardians, endorsing generally the conclusions and recommendations of the Ambulance Cases Disposal Committee.

Need for Additional Voluntary Hospital Accommodation and the Inquiry by the Voluntary Hospitals Commission.

The Voluntary Hospitals Commission have been asked by the Minister of Health to make an inquiry into the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it. The Commission have requested the King's Fund, as Voluntary Hospitals Committee for London, to issue a questionnaire to the hospitals of London, and to transmit the replies to the Commission with a general covering report. LXXXII.—THE TREATMENT OF DYSENTERY.

I.—Bacillary Dysentery.[1]

(A) *Acute Bacillary Dysentery.*

A patient suffering from an acute attack of bacillary dysentery should be put to bed and not allowed to get up for any purpose. The treatment may be conveniently discussed under three headings: (1) diet, (2) the administration of salines, (3) serum treatment.

The *diet* should be fluid, consisting of albumin water, whey, beef-tea, chicken-tea, raw beef-juice, or meat jelly, given in small quantities every two hours. Milk is unsuitable in the acute stage of dysentery, and should be excluded from the dietary. During the first few days the supply of an abundant amount of fluid is of great importance, and the patient should be encouraged to drink as much water, barley-water, or lemonade (only slightly sweetened) as he may desire.

The *administration of salines* is invaluable during this stage. Their action, in no sense specific, depends on a gentle lavage of the intestinal mucous membrane by the copious watery secretions, whereby inflammatory products containing bacilli and toxins are washed away in place of being absorbed. The sulphate of magnesium or sodium, or sodium phosphate may be given, a drachm every two hours during the daytime only, between the hours of 8 a.m. and 6 p.m. Diurnal irrigation of this kind may be safely combined with sedative treatment at night time—e.g., a dose of laudanum or a hypodermic injection of morphia, often needed for the relief of pain and tenesmus, and to promote sleep. After two or three days the quantity of sulphate may be reduced by one half; but the treatment in modified form should be continued until convalescence is established, as it is important that the motions should be prevented from becoming hard and constipated during this perod.

Serum Treatment.—Antidysenteric serum is of the greatest value, and should be given in all but mild cases. Two conditions are essential to success: (*a*) the serum should be administered at the earliest moment; (*b*) it should be given in sufficient quantity. The earlier the stage of the disease, the more effective is the treatment. Its value rapidly lessens with lapse of time, and there is probably little to be gained by initiating serum treatment at a later period than the sixth day. 60, 80, or 100 c.cm. may be injected subcutaneously into the loose tissues of the lateral abdominal wall or elsewhere; the effects of smaller doses are in proportion far less striking. In many instances a single dose is all that is necessary; but if the symptoms are not clearing satisfactorily a second dose may be given after an interval of two days. In urgent cases with fulminating symptoms of choleraic type the serum should be injected intravenously and combined with hypertonic saline solution. The most favourable results may be expected if a serum is used containing exclusively Shiga or Flexner antibodies, according to the type of infection; but in practice no time should be lost by waiting for the laboratory report; the more acute the symptoms, the more likely is the case to be one of Shiga infection, and the best course is to use a polyvalent serum which is known to be rich in Shiga elements. If a second dose is needed, it may consist of pure anti-Shiga or anti-Flexner serum, according to the pathological diagnosis.

The drawbacks to serum treatment are for the most part unimportant. Anaphylaxis is a very rare complication, but its manifestations may be so formidable that it is a wise practice to put the following preliminary questions to the patient: (*a*) Has he had diphtheria? (*b*) Was he on active service during the war? If so, (*c*) Was he wounded; or (*d*) did he suffer from dysentery? In the case of an affirmative answer to any of these queries, the administration of the full dose of serum should be preceded by a tentative injection of 1 c.cm., which will have the effect of unmasking and, at the same time, of removing any hyper-sensitivism that may exist. Serum fever, arising about the fifth day after the injection, with an urticarial or erythematous type of rash, is of no serious consequence. Joint pains, with or without swelling, may occur at the same time or a few days later, and have to be distinguished from true dysenteric arthritis, which, however, is a much more definite and severe form of arthritis, and is comparatively late in its onset.

Convalescence.—The most important consideration in guiding the patient through the stage of convalescence is the management of the diet. This should be increased, as in typhoid fever, by slow degrees, the effect of each addition being carefully watched before any further advance is permitted. Nutritious jellies, egg beaten up in milk, custard, junket, soft bread and milk made without crusts, and milk thickened with farinaceous foods may successively be added. When convalescence is fully established, as shown by a clean tongue and the disappearance of abdominal symptoms, a rapid advance to a normal dietary may with confidence be made; even in cases where the initial symptoms were severe, the progress to recovery may, in the absence of complications, often be surprisingly rapid.

Complications.—Profuse hæmorrhage and perforation are both rare events in the course of the acute stage of dysentery. Hæmorrhage calls for absolute rest, the complete withholding of nourishment by the mouth, and the administration of morphia hypodermically. In severe cases the subcutaneous injection of normal saline, or an isotonic mixture of glucose solution with saline is indicated. In the event of small recurring hæmorrhages rectal injections of copper sulphate, 1 in 1000, may be useful, the mucous membrane having been cleansed by preliminary irrigation with warm water or saline solution. In the unlikely event of perforation during the acute stage an immediate laparotomy affords the only chance of saving the patient's life. In cases of fulminating dysentery with diarrhœa of choleraic type it is important to exclude cholera, which may be done by a microscopic examination of the watery stools and noting the absence of vibrios; the treatment consists of the immediate injection intravenously of a full dose of serum, repeated if necessary, and combined with hypertonic saline solution. Arthritis occurs more often in sequel to a Shiga infection than in cases of Flexner dysentery. It arises usually in the course of the third week, and is accompanied by considerable enlargement and tenderness of the joints, with effusion of fluid. Complete rest of the affected joints is necessary, and much relief may be obtained in suitable cases by tapping and the removal of the fluid. A dose or two of serum may be followed by rapid subsidence of the joint symptoms; but this remedy should be used with caution if serum has been administered during the acute stage, owing to the risk of anaphylaxis. It is a mistake to keep the joints at rest too long; after the subsidence of the acute symptoms, massage and carefully regulated passive movements should be employed, and radiant heat is useful.

(B) *Chronic Bacillary Dysentery.*

Chronic bacillary dysentery is more likely to follow in the course of a comparatively mild Flexner infection than the severer types of Shiga dysentery, and may lead to a clinical condition that calls for the utmost skill and resourcefulness on the part of the physician. As the symptoms of a chronic bacillary infection may closely resemble those of amœbic dysentery, it is necessary as a preliminary measure to make a careful examination of the stools. In not a few cases it will be found that both a bacillary and an

amœbic infection exist side by side, and in such an event a course of treatment with emetine is of primary importance. Wasting is often a marked feature of chronic dysentery, and may be so extreme that the nourishment of the patient becomes the paramount consideration. Under these circumstances better results may be hoped for if the patient is placed on a fairly generous dietary, composed of soft semi-solid articles of food, from which everything of an irritating nature is rigidly excluded, than on a strictly fluid régime. In the management of the bowels constipation may call for the use of sulphates, or in some cases repeated small doses of calomel (gr. ¼ four times in the day) may be remarkably beneficial. In other cases profuse and exhausting diarrhœa is a prominent feature, and may be met by β-naphthol (gr. 5 in cachet four times a day), or bismuth salicylate (gr. 20 four times a day). Lavage of the intestine is more often useful than in acute dysentery; a long soft tube should be employed, and the fluid allowed to flow in gently through a funnel by gravitation. Dilute solutions of antiseptics, such as eusol, or of astringents, such as silver nitrate or copper sulphate (1 in 1000), may be used, but it may be regarded as doubtful whether these have any real advantage over cleansing injections of warm boric or weak permanganate solutions, or even of warm saline. A considerable number of cases ultimately prove refractory to all forms of medical treatment, and in these the question of securing a more efficient degree of lavage by appendicostomy should be considered, or complete rest for the lower bowel may be temporarily provided by arranging for the evacuation of the fæces through an opening in the cæcum. Vaccine treatment has been employed with a certain measure of success. Perforation is a more likely complication of chronic than of acute dysentery; owing to adhesions the resulting peritonitis is often localised, and ultimately a large circumscribed abscess may be formed. On account of the chronic nature of the process the clinical picture is often quite indefinite, and the condition may exist for some time before it is recognised; the treatment is surgical.

---

[1] The Treatment of Amœbic Dysentery will be dealt with in The Lancet next week.

Physician, Royal Free Hospital, London.

Special Articles.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE Prince of Wales presided at a special meeting of the President and General Council of King Edward's Hospital Fund for London at St. James's Palace on July 25th.

Lord Stuart of Wortley, chairman of the Management Committee, presented a report on the recommendations of the Ambulance Cases Disposal Committee dealing with the need for additional voluntary hospital accommodation, the inquiry now being conducted by the Voluntary Hospitals Commission; and the bequests of the late Mr. and Mrs. Wells.

Recommendations of the Ambulance Cases Disposal Committee.

The Management Committee asked the views of the Distribution Committee on the recommendation—

> That King Edward's Hospital Fund, in making its annual grants, should take into consideration whether hospitals which deal with cases of accident or sudden illness occurring in streets or public places provide (*a*) a reasonably sufficient number of beds for such cases, (*b*) a reasonably sufficient number of observation beds or beds attached to the casualty department, in order to avoid, as far as possible, transfer to another institution of any patient whose condition might be likely to be prejudiced by such transfer.

The Distribution Committee have expressed their willingness to carry out this recommendation and have asked the hospitals for particulars of their available bed accommodation under these heads, and for their views as to its adequacy. The Ambulance Cases Disposal Committee, in their report, referred to the fact that most of the cases of alleged unnecessary or injurious transfer of patients had been reported from Lambeth. They associated this fact with the general shortage of voluntary hospital beds in South London, where King's College Hospital has only been able, since the war, to keep open 226 beds for ordinary patients out of 388 provided in 1913 for the specific purpose of reducing that shortage. The opinion expressed by the Ambulance Cases Disposal Committee in March was strengthened in April by the occurrence of two further cases of transfer from King's College Hospital for want of beds. The Distribution Committee are accordingly paying special attention to the question of the supply of beds for accident cases in South London, and particularly at King's College Hospital. The Management Committee invited the observations of the police and ambulance authorities on the recommendation—

> (*a*) That it be represented to the police and ambulance authorities that no institution which is not equipped for the reception and treatment of serious cases of accident or illness should be retained on the list of institutions to which ambulance cases should in the first instance be taken.
>
> (*b*) That it be suggested to the authorities that in drawing up the list of such institutions the coöperation of the Ministry of Health be sought in the case of infirmaries, and of King Edward's Hospital Fund in the case of hospitals.

It will be noticed that this recommendation deals primarily with the provision of emergency treatment in the first instance, as distinct from the provision of beds, which is dealt with in the previous recommendation. The London County Council has concurred in both parts of the latter recommendation and has given directions for them to be carried into effect by the London Ambulance Service.

The Management Committee also considered a recommendation—

> That it be represented to the Ministry of Health that in the case of street accidents or sudden illness brought to Poor-law institutions (including "removals" from the casualty department of a voluntary hospital): (*a*) no question of residence of the patient, or site of the accident, or site of the transferring hospital, should be raised prior to reception and treatment; (*b*) no such cases should be transferred to another institution if their condition might be likely to be prejudiced by such transfer; (*c*) the charge for treatment of such cases should be a common metropolitan one, and not fall on the union receiving and treating such patients; (*d*) such patients should not be subject to any disability arising out of technical pauperisation as the result of their reception and treatment.

These changes would remove certain difficulties which now sometimes prevent an accident case from being taken to the infirmary which lies nearest.

The Management Committee addressed a letter to the Ministry of Health, urging upon his consideration their view that these proposals should be the subject of early legislation or administrative action. In doing so, they drew the Minister's attention to a resolution passed on May 29th by a conference of representatives of Metropolitan Poor-law Boards of Guardians, endorsing generally the conclusions and recommendations of the Ambulance Cases Disposal Committee.

Need for Additional Voluntary Hospital Accommodation and the Inquiry by the Voluntary Hospitals Commission.

The Voluntary Hospitals Commission have been asked by the Minister of Health to make an inquiry into the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it. The Commission have requested the King's Fund, as Voluntary Hospitals Committee for London, to issue a questionnaire to the hospitals of London, and to transmit the replies to the Commission with a general covering report. The report will be prepared by the Management Committee with the assistance of the Distribution and Hospital Economy Committees. It was already known to the King's Fund that num schemes of extension or improvement, unavoidably postponed during the war and the subsequent financial crisis, had been and were being taken up by the hospitals themselves. Several have been completed, others are in hand, and others again have been passed by the King's Fund with a view to early action. The number of beds available at the hospitals on the books of the King's Fund has increased from 11,800 in 1913 to 13,400 in 1924, and the schemes now in hand or proposed would add another 1000 beds. During the last three years the hospitals of London, besides increasing their income from £2,430,000 to £2,850,000, adding £991,000 to their endowments, and obtaining more than £400,000 through the combined appeal, have received about £1,100,000 for extensions and improvements. A large sum is, however, still required to meet the capital expenditure on these schemes. The grants from the King's Fund in aid of such schemes were reduced to a minimum in 1921, and, although they have been again increased in subsequent years, they do not yet amount to the same proportion of the capital cost of the schemes, or of the total distribution by the Fund, as they did before the war. Additional income will also be required for the maintenance of the increased number of beds.

Bequests of the late Mr. and Mrs. Wells.

The Management Committee have had before them for some time the question whether the King's Fund could take definite action to help the hospitals to meet these needs. It so happened that in February last, just when the Ambulance Cases Disposal Committee was considering the connexion between the lack of sufficient accident beds and the general question of the shortage of hospital beds, particularly in South London, the King's Fund was notified that a large sum, estimated at more than £200,000, would shortly be received under the wills of the late Mr. and Mrs. Wells. The custom of the General Council, in dealing with legacies which it has power to spend, has usually been to invest part and distribute part. It would thus be consistent with previous policy if the King's Fund, having recently invested more than £1,100,000 from the bequests of Lord Mount-Stephen and Sir Thomas Sutherland, were to include the Wells legacies of £200,000 in the estimates of the amount available for distribution if required. This is specially the case when, as at present, the hospitals are faced with various exceptional needs, such as those mentioned above. The Management Committee accordingly consulted the Distribution Committee as to the best method in which, should the General Council approve, the Wells legacies could be used for this purpose, and have received from them the following statement:—

(i.) The Distribution Committee cordially support the suggestion that the Wells legacies should be used to assist the hospitals to meet special needs.

(ii.) The Distribution Committee are of opinion that the following method of applying the legacies, in whole or in part, could usefully be considered: (*a*) Assistance in the provision of additional hospital accommodation, including accommodation for accident cases, by grants towards capital expenditure on schemes of extension, or towards the reduction of deficits on schemes that have been completed, or towards the opening of beds in extensions that have already been provided but are not yet available for the patients for whom they were intended; (*b*) assistance towards schemes of improvement as distinct from schemes of extension; (*c*) increased grants to maintenance, including the maintenance of additional beds.

(iii.) In connexion with the provision of additional accommodation, including accommodation for accident cases, the Distribution Committee consider that there is urgent need for a further step towards the completion of the full service of King's College Hospital, where 162 of the 388 beds provided in 1913 by the removal to Denmark Hill are still not available to meet the shortage of beds in South London.

(iv.) The Distribution Committee think that, when they are preparing proposals for the application of these exceptional legacies, they will sometimes find it desirable that definite conditions should be attached to the grants—e.g., a condition that beds should be opened, or that beds should be reserved for accident cases, or that a scheme should be put in hand at once, or that the balance required, or a specified part thereof, should be raised. In some instances it would be an advantage that the Committee should be in a position to make a definite arrangement in advance with the hospital concerned. In suitable cases the exceptional grants might be used in this way to stimulate fresh activity on the part of hospitals.

(v.) Under the scheme outlined above, the whole amount would not be distributed at once. For example, grants for the opening of beds would be spread over a period of years; grants in aid of extensions and improvements need not be wholly confined to schemes already submitted; and part of the sum received from the legacies might be retained for the present in case new needs should arise.

In conclusion, the Management Committee approve generally of the proposals contained in the report.

Lord Stuart, in moving the adoption of the recommendations, said that the replies to the interrogations issued at the request of the Hospitals Commission gave evidence of the care which the hospitals were giving to the answers. Lord Revelstoke, honorary treasurer and chairman of the Finance Committee, seconded the proposal and was supported by Sir Cooper Perry, chairman of the Distribution Committee, and Sir William Collins, chairman of the Ambulance Disposal Committee. The motion was carried unanimously.

The Prince of Wales, after reading a letter from the King in which His Majesty endorsed the action of the Management Committee and expressed his gratification that the Fund should be in a position to afford at the present time special assistance to the voluntary hospitals, continued:—

"I wonder if there is anyone who still thinks the voluntary hospital system is dead, or dying. If so, let him look at the facts and figures before us to-day. Even in 1920, when the crisis was at its worst, the hospitals of London had an income of £2,400,000 as against £1,500,000 before the war. Since 1920 their income has increased to £2,850,000, without counting any of the £400,000 raised by the Combined Appeal; £990,000 has been added to their endowments; and £1,100,000 has been received for extensions and improvements. This means that, over and above their annual income, which last year was nearly twice what it was before the war, the voluntary hospitals, in London alone, have received in three years two and a half millions for special purposes. And this does not include the additions, during this same period, to the investments of the King's Fund itself. Then, again, there are 1600 more beds than there were before the war, and the extension schemes now in hand, or proposed, would add another 1000. This is not decay or death. It is life—and very vigorous life. More than that, it is growth. The hospitals are not satisfied with merely making both ends meet—difficult as that seemed a short while ago. They are constantly expanding in response to the ever-growing need for better equipment and more beds. Even during the crisis they never quite stopped doing this. Extensions and improvements, like so many other good things, were delayed by the war, but they still went on here and there. After the war new schemes came with a rush; so much so that the King's Fund had sometimes to act, much against its will, as a restraining force; taking the view that, except in specially urgent cases, the maintenance of the hospitals, as a whole, must have precedence over appeals for capital expenditure in any particular instance. The distribution of the surplus funds of the Red Cross Society and the Order of St. John, through the King's Fund, helped a large number of schemes. Nevertheless, a good many had still to be postponed.

But gradually the position has changed. With the aid of the temporary Government grants and the Combined Appeal, most of the deficits are paid off. Income of all kinds, voluntary contributions, patients' payments and workmen's collections, the ordinary distribution of the King's Fund, all are increasing. There are, unfortunately, some institutions still in grave financial difficulties. And the hospitals are all faced with the increased expense involved in new methods of medical diagnosis and treatment. But, taken as a whole, they have been able to turn their attention more and more to extension. The King's Fund last December increased its grants in aid of schemes. The public, which by its gifts helped to save the hospitals in 1922, is now, with equal generosity, supporting their new ventures. More than one large appeal for special objects, such as endowment, reconstruction or extension, has in recent months been conspicuously successful."

Continuing, the Prince said now that the Council had approved the general principle, the Distribution Committee could prepare plans for the actual use of the money. They had already collected a good deal of information about the most urgent needs of the hospitals. One of these, the need for additional accident beds, especially in South London, had been brought before the public more than once in recent months, and it was gratifying to hear from Sir Cooper Perry that the decision of the King's Fund would enable immediate action to be taken to meet that need. The Distribution Committee had also before them a long list of schemes of extension and improvement, and there were other special needs. The King's Fund was making its special contribution to the forward movement, but it could not be, and did not want to be, a substitute for that individual interest and individual effort which, under the voluntary system, was the source of life to the individual hospital. The King's Fund had its own particular function. It was concerned with the needs of London as a whole, and with the relative needs of the different districts. It had exceptional means of comparing the circumstances of the various hospitals. And where a donor or a testator was not specially interested in any one institution, but desired to benefit the hospitals of London generally, or to have his gift distributed in proportion to needs, he could, if he so wished, avail himself of the facilities of the King's Fund.

The meeting closed by a vote of thanks to the Prince of Wales, moved by Lady Ampthill and seconded by the Chief Rabbi, which His Royal Highness briefly acknowledged.

THE NUTRITION OF MINERS AND THEIR FAMILIES.

IN the autumn of 1922 considerable public attention was directed to the state of affairs in the coal-mining industry. For various reasons of economic sort the prosperity of persons employed in this industry was greatly depressed, and it was freely stated that the available income of families dependent upon the mines for subsistence was insufficient to provide the bare means of life. Questions were asked in the House of Commons, but no detailed evidence as to the precise domestic circumstances of the miners' families was available. The Committee on Quantitative Problems of Human Nutrition appointed by the Medical Research Council decided, with the financial support of the Department of Mines, to investigate the matter, and the result of this investigation has now been published.[1]

The food requirements of man are first set out and a provisional assessment is made of the needs of the coal-miner. The study of family budgets forms the next section of the report, with an account of the method of inquiry pursued by the Committee. A critical discussion follows, and then a tabular statement of the height and weights of the children of miners. Finally, certain general conclusions are reached which are set out below in the words of the Committee:

General Conclusions.

The material upon which this report is based is too scanty to authorise any sweeping conclusions, but is, in our opinion, so accurately compiled that a high degree of probability attaches to some inferences, but before noting them the following points must be borne in mind and any conclusions must be interpreted in their light.

(*a*) Many of the families investigated were burdened by debt, the aftermath of the strike, and therefore a wage, which might have been sufficient to provide an adequate supply of food, was so reduced as to make living difficult.

(*b*) In some of the families, at least, the amount of money allowed to the wife, for the purchase of food and the household expenses generally, bore no relation to the wage earned, and it is not known in these cases exactly how much was actually earned.

(*c*) It must again be emphasised that, when comparisons are made between the physical condition of the miners' children and those of the general average for the county area, the numbers of miners' children studied were very small. In some groups the numbers for comparison were as low as two. Another point in this connexion on which we have no direct evidence is whether or not there is any hereditary difference as regards physical condition between the average mining class and the average population of the areas investigated.

Subject, then, to these limitations we conclude:—

1. That during the period of observation (December, 1922, to March, 1923) the average consumption of food in one district, Derbyshire, was sufficient to maintain healthy existence, and, in that district, the children of the miners whose family diets were studied differed in respect of height and weight in no significant way from the average of the whole county.

2. That the diets of the four other districts, and in particular of the Durham area, if the energy requirements in these areas be comparable with those of Derbyshire, fell somewhat below the standard generally accepted as satisfactory. In Durham the children measured were in respect of weight slightly below the county average.

3. That quite apart from differences of income there are variations of diet from district to district and within each district which suggest that housewives could be helped to secure a more adequate return for their expenditure by a better dissemination of knowledge both of the economic and hygienic aspects of diet. There is evidence that in the districts where bread is baked at home the diets are more satisfactory.

4. The absence of a definite correlation between the weights of the children and the calorie intake seems to indicate that factors other than diet, so far as examined in this report, influence the state of nutrition of these children.

5. That there is evidence which would suggest that the diets of families of which the mother had had training in domestic service are better than the average, but the evidence is not conclusive.

The personnel of the Committee upon Quantitative Problems in Human Nutrition responsible for this report is as follows: Prof. E. P. Cathcart, M.D., F.R.S. (chairman), Dr. Major Greenwood, Dr. Leonard Hill, F.R.S., Dr. A. W. J. MacFadden, Sir Thomas Middleton, Prof. D. Noel Paton, M.D., F.R.S., and Prof. T. B. Wood, F.R.S.

In tending their report, the Committee express cordial thanks to various medical officers of health who collaborated with them in this inquiry, and also high appreciation of the work of the field investigators. It is evident that there has been a close and harmonious coöperation between these workers and the staffs of public health departments, which is of happy augury for the success of other investigations which it may be found desirable to undertake in the future.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Register and the Irish Free State.

THE Government of the Irish Free State has taken an important step to avoid the difficulties which had arisen in regard to the admission to the Medical Register of licentiates and graduates educated in the Free State. A Bill has been introduced, and rapidly passed through the Dail, authorising the General Council established under the Medical Acts to continue temporarily to exercise jurisdiction and authority under those Acts in respect of medical practitioners in the Free State. The Bill sets out that the General Council and the Branch Council are to have the same authority, and medical practitioners in the Free State the same rights, privileges, and immunities, and be subject to the same obligations as prior to the establishment of the Free State. The General Council and the Branch Council are to continue to be nominated, chosen, and elected in the same manner as heretofore. The Medical Acts are to continue to have effect in the Free State. The duration of the Act is one year from the date of its passing. The Bill passed rapidly through the Dail and has passed its second reading in the Senate without serious opposition. It is understood that, during the year's grace which this Bill will allow, the whole question will be thoroughly studied, and that the Government will then, after consultation with the medical profession, promote considered legislation.

Dedication of Queen's University War Memorial, Belfast.

The chief object of the visit of the Duke and Duchess of York to Northern Ireland was the dedication of the war memorial at the Queen's University, which took place on Monday, July 21st. The Duke and Duchess were received by a large assemblage fully representative of the University and the City of Belfast, and prior to the dedication ceremony received the honorary degree of LL.D. at the hands of the Chancellor of the University, Lord Londonderry. The war memorial stands in front of the principal entrance to the University. It consists of a fine bronze statue of a winged Victory, bearing in one arm the figure of a dying soldier and raising the other arm to uphold a crown of laurel. The pedestal of granite bears the names of 253 fallen Queensmen commemorated on attached bronze tablets. The work was designed by the late Sir Thomas Brock, and after his decease was finely executed by his assistant, Mr. Arnold Wright. The Chancellor of the University opened the dedication ceremony with a brief speech recalling the services of Queensmen in the late war, and the Duke of York then unveiled the memorial. Dr. Simms, M.P., principal chaplain to the British armies in France, pronounced the dedication, and a reveillé was sounded by four buglers, followed by a prayer. Numerous wreaths were placed at the foot of the pedestal of the memorial. After the ceremony the Duke and Duchess were entertained to luncheon in the Great Hall of the University by the Chancellor and Lady Londonderry. About 200 guests sat down, the company including the Governor of Northern Ireland, the Vice-Chancellor of the University (Dr. R. W. Livingstone, M.A.), and the Lord Mayor of Belfast. Replying to a toast, the Duke of York referred to some of the recent benefactions to the University, especially the foundation of Riddel Hall as a hostel for women students, and the new gates to the University, the gift of Mr. F. A. Heron, D.L.

Strike of Municipal Workers in Dublin and Suburbs.

A strike has taken place on very brief notice on the part of the municipal workers of Dublin and the adjoining townships. It appears that at a conference held recently between the several local authorities it was decided to recommend a reduction in wages of 6*s.* a week, beginning with a cut of 2*s.* on Sept. 1st. The recommendation of the conference had not yet come before the local authorities and no decision had therefore been made. On July 19th the workers withdrew from work. Several essential services are left derelict. Fortunately the drainage system can be carried on, though the sewage is discharged once again into the Liffey, as in the time prior to the construction of the Dublin main drainage system. Electricity has failed, however, both for lighting and for other purposes. Street cleansing is also stopped, as well as removal of house refuse. The city markets, through which all vegetables and greenstuff reach the consumers, may be stopped. The strike is certain to have its effect on the public health. The action of the workers in precipitating a strike on the eve of the Dublin horse show and the Tailteann games, for which the city has been long preparing, has roused much local indignation.

The late Dr. Arthur W. W. Baker.

The death occurred recently at his residence in Dublin of Arthur W. W. Baker, M.D., M.Dent.Sci. (Hon.), F.R.C.S. Irel., long regarded as the doyen of the dental profession in Dublin. He was 72 years of age. Having taken his medical degrees in Dublin University in 1875, he chose dentistry as his specialty. He was for many years one of the leading spirits in the management of the Dental Hospital of Ireland, and the foundation and success of the School of Dentistry attached thereto were mainly due to his activity and care. Some 20 years ago, acting under his guidance, Trinity College established a school of dentistry, and the first degree in dentistry conferred by the University was the Honorary Degree of Master in Dental Science conferred on Dr. Baker. He was closely associated with the Officers' Training Corps of Dublin University, and during the war he held the rank of captain in the Royal Army Medical Corps, serving for a time in the Dublin (83rd) General Hospital at Boulogne. He was a man of much general culture as well as of learning in professional matters. He was specially interested in music, and much of his leisure was spent in yachting.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Speech Pathology in Vienna: The First Congress.

THE first Congress of Speech Pathology was held in Vienna for three days in the early part of July under the presidency of Dr. Fröschels (Vienna), and was attended by laryngologists, speech-pathologists, and linguists from all parts of Europe, as well as by members of the Government, when discussions took place on the problems of normal and defective speech.

The rise of Vienna to be the centre of speech study began with the work of Prof. Brücke, the physiologist, who made the first accurate studies of enunciation. Under his successor, Prof. Sigmund Exner, the Academy of Sciences founded the first Phonogram Archiv. Two large speech clinics have been in existence for many years. The only society for experimental phonetics is that in Vienna, and with the recent opening of a laboratory for experimental phonetics there has been a revival of the opportunity to study the science.

The Congress was opened by Dr. H. Stern, director of Prof. Hajek's clinic for laryngology, who delivered a memorial address in honour of Gutzmann, the "father of voice and speech pathology." Dr. Fröschels then read a paper on aphasia, in which he stated that although it was not yet possible to localise with accuracy the various forms of this condition, careful training of the patient gave most excellent results, even in cases of long standing. An interesting discussion followed, in which Drs. Stojanovics (Jougoslavia), Bonvicini (Italy), Pappenheim and Richter (Germany) took part. Prof. Winkler (Vienna) then demonstrated the induction of aphasia in a young lady by means of hypnotism, and Drs. Allers and Freund emphasised the important part played by complicated mental processes in the act of "finding the word." Dr. Eliasberg (Munich) read a paper on methods of testing the intellect through the speech, and Dr. Stein (Vienna) dealt with the condition known as *dysarthria articulæ universalis*, or general stuttering.

Speech in Nervous Diseases.

On the second day Prof. E. W. Scripture (London) reported in brief the results of work done in London in this subject by means of recording and analysing speech in nervous diseases. By this method he established that the changes of speech in a disease or a lesion of any part of the nervous system showed an absolutely constant and unchangeable type for this part. The records of speech showed specific alterations in bulbar paralysis that did not occur in any other disease, and again there were specific alterations found in cerebellar troubles. The speech abnormalities in the case of a nerve lesion changed only progressively or regressively and never altered their type. In his opinion it was possible from the speech curves alone to diagnose such troubles as progressive bulbar paralysis, disseminated sclerosis, general paralysis, and epilepsy. Speech in idiopathic epilepsy had a peculiar character found in no other trouble, and this characteristic indicated that the condition was not a localised affection of the cortex, but a generalised anomaly of the constitution.

Stuttering.

On the second day Dr. Hoepfner (Saalfeld) opened a discussion on stuttering. He considered that the popular term "stuttering" had hindered research and treatment in this condition, as it did not give proper credit to the various ætiological factors, particularly those of pathological anatomy, which caused the defect. He believed that the majority of such cases must be termed "associative aphasia"—that is, a disturbance of the equilibrium of the psyche produced by the preconceived idea of being unable to speak correctly. This occurred generally at a very early age.

Prof. Scripture thought stuttering was an inferiority neurosis directed toward persons who could hear, and found support for his theory that the inferiority neurosis was due to diminished activity of the suprarenal cortex in the favourable results obtained by administering preparations of this part of the gland.

In the long discussion which followed Dr. Fröschels admitted the psychic factor, saying that many stammerers were "bullied" by the idea "I cannot speak." Dr. Hetsche and Dr. Gumpertz (Berlin) opposed the use of the term aphasia for this condition; but Dr. Stern believed that a large number of such affected persons suffered from a true "temporary associative aphasia," and he considered this condition was amenable to appropriate therapeutic measures. A number of papers dealt with the beneficial effects of special classes for children with speech defects, where they were segregated from normal-speaking pupils. Prof. Hajek gave an interesting paper on the voice, speech, and music of wild tribes, illustrated by a number of gramophone records.

On the third day of the Congress the subject dealt with was

Diseases of the Voice and their Cure.

Dr. Stern opened the discussion with a very lucid and exhaustive paper. He explained the condition of phonasthenia (functional tiredness and weakness of the voice), and his methods of treating the voice of singers. He strongly advocated "washing out the larynx" with warm physiological salt solution. The phonetic laboratory under Dr. Stern in Prof. Hajek's clinic made a special point of studying troubles of the singer. Several forms of treatment were demonstrated. Although this subject was of greatest importance for large numbers of singers and vocal students, he said, it fell outside the interests and knowledge of the professional laryngologists, and could be pursued only by the special type of physician who was both a laryngologist and a voice specialist.

Of the ground covered by other papers read at the third session a brief résumé only can be given. Mr. Brömme (Frankfort) explained his methods of developing the voice; Dr. Demetnades (Athens) gave an account of the relationship between the control of the circulation by the sympathetic nervous system, the resonance of the skull, and the formation of the voice; Dr. E. Richles showed the importance of experimental phonetic methods in historical ethnographic researches; Dr. Wilheims spoke on the value of the speech as a factor in individual psychology; and Dr. Fröschels and Dr. Frajan recorded some experimental observations made during the teaching of speaking. It was resolved to present a more detailed report on this subject at the next Congress, which will be held in two years' time. At the end of the session the "Logopedic and Phoniatric Society" was founded, Prof. Scripture being elected president, with Dr. Stern, Dr. Fröschels, Mr. Rothe, and Dr. Hoepfner as members of committee.

Demonstration of Stomach Speech after Laryngectomy.

As a final act of the Congress a demonstration of patients and apparatus at the phonetic department of the clinic for laryngology was given.

Dr. Stern showed four patients: (1) A woman in middle life spoke distinctly in short sentences with a scratchy kind of voice. On lifting a neck ornament she exposed the opening into the trachea through which she breathed. Dr. Stern explained that she had been taught to swallow air into the stomach before each sentence, and to speak by pressing this air out against resistance at the top of the œsophagus. The vibrations at the opening of the œsophagus produced the tone, and the air from the stomach supplied the speech organs for enunciation. (2) A motor-car dealer in excellent health who could be heard to swallow the air before each sentence. He spoke fluently and loudly, and stated that he talked without any effort all day long. (3) A man in middle life who talked without difficulty and who could sing in a crude manner over two octaves. (4) A lady who had only been a month in training and had got only far enough to do syllables well.

The education in stomach speech requires training for one or two years. It succeeds well with many patients but not with others. The teaching of the stomach speech requires skill and practice on the part of the physician. The technique of the operation for laryngectomy and of the after-care has been so wonderfully developed in Prof. Hajek's clinic that the mortality is very small.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Meeting of the Aerzte-Vereinsbund.

THE Aerzte-Vereinsbund (the Association of German Medical Societies), a body dealing not with scientific but with professional questions, held a general meeting recently at Bremen. This was the first general meeting after an interval of three years, during which time the financial condition of Germany and of the medical profession necessitated a lapse of the annual meetings. The meeting was attended by 429 delegates of local medical societies, and first discussed the question of courts of honour. These courts are not instituted by law throughout the whole of Germany. In Prussia and in some of the Federated States they are so established, but they are not legal in Bavaria, Wurtemberg, and Oldenburg. It has been suggested in Parliament by the Social-Democratic party that they should be completely abolished, but the Prussian medical chambers with which the courts are connected protested unanimously against this suggestion. After a long discussion the association agreed almost unanimously that the courts of honour ought not only to be maintained where they are already working, but that they should also be introduced into those of the German Federated States where they did not already exist. The association also desired that medical men who were under the disciplinary power of the Government but not under that of the medical courts of honour (such as medical officers of health, army and navy medical officers, and university teachers), should not be exempted from the jurisdiction of the courts. As hitherto, in cases of unprofessional behaviour the courts could only fine a defendant and withdraw his right of voting for the medical chamber, a purely nominal penalty to medical men of a low professional standing. The meeting proposed that the courts be authorised to exclude a medical man from practice in cases of grave misdemeanour. Concerning the workmen's insurance laws, it was proposed at the meeting that compulsory insurance against illness ought to include only persons earning less than M.2400 (£120) per annum, and that no person should be authorised to remain a voluntary member of a sick-club under the Workmen's Insurance Act if his earnings were more than M.4000 (£200) per annum. The meeting then discussed the question of life insurance of the members of the profession themselves and their insurance against accidents, and agreed that such insurance should be compulsory. The amalgamation of the association with the Leipziger Verband was declined, although both societies have worked together, and will continue to work together in matters concerning the general welfare of the profession.

A Leech in the Larynx.

Dr. Messinger, a German medical man residing in Veles, Macedonia, reports a case in the *Medizinische*

Klinik where a woman in drinking water from an earthen pot suddenly felt a foreign body in the larynx, which gave rise to severe fits of coughing with hæmorrhage and dyspnœa. Neighbourly attendance proved useless, and six days later she was brought to the doctor in a very anæmic and weak condition. Dr. Messinger ascertained that the larynx and its surroundings were greatly swollen and inflamed, and covered with hæmorrhagic spots; by laryngoscopy the head of a leech could be seen in the rima glottidis attached to one vocal cord. Under local cocaine anæsthesia Dr. Messinger tried to seize the head of the animal with forceps, but did not succeed. He then touched its head with a concentrated solution of kitchen salt, with the result that the leech loosed hold of the vocal cord and disappeared into the interior of the larynx, whence it was discharged through the rima glottidis by a very strong attack of coughing. It is remarkable that the leech managed to remain in the larynx for six days undisturbed by the violent coughing.

Visa to Passports of Foreign Patients.

The Committee of the Medical Chambers have informed the Government that complaints have been made by foreign patients, on the ground that German consulates abroad have often declined to visa passports of foreigners desiring to go to German spas or to consult German specialists. The Foreign Office has answered that they had instructed the German consulates abroad to be as liberal as possible in the interest of German spas and medical men, but that such liberality has been greatly abused, especially in certain Eastern countries. In one of the consulates in the East it was stated that of 54 visas given for a visit to German spas in three cases only did the supposed patients really go to the health resort. Many undesirable foreigners try to use such visas to secure a prolonged stay in Germany, sometimes for illegal business. If the visa is declined they approach the representatives of the profession and complain of not being admitted to Germany. Giving visas indiscriminately to every alleged patient has therefore been discontinued in certain Eastern countries where the abuse has been in evidence.

Spread of Tuberculosis in Children.

Dr. Thinius, physician to a dispensary for tuberculous children, has recently carried out an investigation into the presence of tuberculosis in school-children. He selected for the investigation the town of Stolp, a country centre in Pomerania, with 35,000 inhabitants, where the housing accommodation was somewhat unsatisfactory. As the parents had been informed by the local press and by lectures of the importance of the investigation, Dr. Thinius was allowed to examine 4400 of 6900 school-children. Pirquet's reaction was used as a test for the presence of tuberculosis. It was found that of the 4400 children 39 per cent. gave a negative and 61 per cent. a positive reaction. A noteworthy fact was that in college youths of the relatively better-off class a positive reaction was just as frequent and sometimes even more frequent than in the pupils of the elementary schools of the town. The school for feeble-minded children showed the highest percentage of positive reactions—viz., 87. The average percentage of positive reactions increased with the age, being 47 at the age of 6 years and 65 at the age of 16.

Metropolitan Ear, Nose, and Throat Hospital.—The eighty-fifth annual report of this institution shows that the total income for the year 1923 was £4581, almost identically the income for the previous year. The total ordinary expenditure amounted to £3505, as compared with £3532 during 1922. The number of patients attending the out-patient department was 3667, and the total number of in-patients was 693; practically speaking, in both categories males and females were almost equally divided. The report contains tables setting out the number of cases treated for each disease coming within the special department with which the hospital deals.

Medicine and the Law.

The Costs in the Harnett Case.

Mr. Harnett, the plaintiff in the action against Dr. C. H. Bond and another, was unsuccessful in an application to the Court of Appeal asking that an order of the court as to costs should be stayed pending an appeal to the House of Lords. When the Court of Appeal, in May, allowed the appeal of Dr. Adam and ordered a new trial of the action against Dr. Bond, the usual order was made for the costs of the original action and of the appeal to be paid or provided for by Mr. Harnett before the taking of any further proceedings. It was in order to obtain a stay of this order as to costs, pending an appeal to the House of Lords against the judgment of the Court of Appeal, that the application referred to was made before the Master of the Rolls (Sir Ernest Pollock), Lord Justice Warrington, and Lord Justice Atkin. In giving judgment, without calling upon counsel for Dr. Bond and Dr. Adam, the Master of the Rolls referred to the order of the Court of Appeal as possibly inconvenient to the plaintiff, but as not rendering appeal to the House of Lords impossible. The argument on behalf of the plaintiff had shown no ground for the court exercising its discretion in the manner asked.

Manslaughter of a Child.

At the Central Criminal Court recently, the trial took place of C. W. Travis, an American subject, who has been stated to have had some medical training. He was indicted for murder and found guilty of manslaughter, having killed his own son, 10 months of age, by closing its mouth and nostrils with his hand when irritated by the child crying at night, his defence being that he thought he could induce sleep through exhaustion, following deprivation of air. Mr. Justice Shearman postponed sentence for a day, and then said that he found the problem of how to deal with the prisoner difficult. The jury had found that he had not intended to kill the child but had done so owing to a criminal impulse and with great cruelty. He had reports before him, as well as the evidence of Dr. H. A. Grierson, medical officer of Brixton Prison, to the effect that the prisoner was a man of exceptional intelligence, but not normal mentally and liable to criminal impulses. At the same time there was no question that as far as legal responsibility was concerned he was perfectly sane. His Lordship referred to the power of the Home Office to deal with the case after full consideration of the mental state of the prisoner and passed a sentence of penal servitude for five years. This appears to have been the best way to deal with the case in the circumstances. There was no evidence to show that Travis did not know the nature and quality of his act and that it was wrong, though he may have failed to appreciate the danger of depriving his child of life by the method that he adopted to keep it quiet when "teething." Having killed it he took the body in a bag to Birmingham and left it in the cloak-room at the railway station. His case will no doubt be considered before he undergoes penal servitude as a sane convict.

Dirty Ice-cream.

At Old-street police court recently a man was fined 40*s*., the maximum penalty, and one which the magistrate, Mr. Clarke Hall, observed was altogether inadequate, for manufacturing and storing "ice-cream" in a manner that exposed it to contamination. The compounding of the "ice-cream," which, as is well known, is mainly sold to children of the poorer class, was shown to have taken place in a back room and in a yard where there were found pails filled with the mixture in close proximity to an open dustbin and to refuse lying in the yard. In comment it may be observed that it is not unusual in Acts of Parliament concerning the public health to provide a penalty which may be adequate for an offender who has transgressed for the first time and perhaps ignorantly or inadvertently, but that such penalties may not be enough to deter from perseverance in a profitable trade, constant inspection of which by the authorities is not easy. It was stated that this man had been warned not once but many times with regard to his dangerous methods. Dr. G. E. Oates, who, as medical officer of health for Bethnal Green, caused him to be prosecuted, is to be congratulated upon having succeeded, at any rate, to the fullest extent permitted to him by the law.

Cotton-Spinners' Cancer.

On July 26th Judge Mossop gave a written judgment in the important claim in Ashton-under-Lyne County Court[1] for compensation by an operative mule-spinner, Harry Whiteley, of Dukinfield, on whose behalf it was alleged that he had contracted epithelioma of the scrotum in the course of his employment with the Atlas Mill Co., Ltd., Ashton. The claim for compensation was made under Schedule 12 of the Industrial Diseases Act. The point at issue was whether the disease was contracted in the course of Whiteley's employment, and for which he should be compensated. The amount of the claim was £26 5s., being 15 weeks at 35s. per week. The judge held that the applicant was entitled to compensation for personal injury by accident or disease arising out of and in the course of his employment within the meaning of the Workmen's Compensation Act, 1906. He summed up the case as follows:—

(1) "He (the applicant) contracted the disease known as cancer of the scrotum.

(2) "This disease manifested itself for the first time whilst he was employed by the respondents who were his last employers.

(3) "His employment brought him into contact with a moving bar which caused constant friction close to the scrotum.

(4) "His employment involved his overalls near the scrotum being constantly sprinkled with mineral oil.

(5) "Mineral oil is an irritant.

(6) "The applicant. when at work, used overalls which could be easily penetrated by the oil.

(7) "The atmosphere in which he worked was humid.

(8) "Investigation has proved that cancer of the scrotum is quite common amongst mule-spinners.

(9) "Combine the facts number one to seven and the conclusion is irresistible that there is a connexion between the disease and the employment, and I so hold."

Judgment was given for £26 5s. and respondents to pay the costs, and that the order would be for a declaration of liability on the part of the employers for the disease at any time hereafter. The case was regarded as a test case, and much importance is attached to the judgment. having regard to the fact that many more claims may depend on it.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. H. A. Browning is placed on Retd. List at own request.

Surg. Lts. to be Surg. Lt.-Comdrs.: A. W. Cocking and W. E. Heath.

ROYAL ARMY MEDICAL CORPS.

TERRITORIAL ARMY.

Maj. W. Haig resigns his commn. and retains the rank of Maj. with permission to wear the prescribed uniform.

Capt. H. M. Anderson (late R.A.M.C.) to be Capt.

Lt. D. J. Davies to be Capt.

Capt. C. D. Walker to be Lt. and relinquishes the rank of Capt.

D. P. Levack, J. A. Stobbs, and T. H. Sansome to be Lts.

INDIAN MEDICAL SERVICE.

Lt.-Col. Chintaman Ramchandra Bakhle to be Col.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS.

The quarterly meeting of the committee was held at 11, Chandos-street, on July 18th, when Colonel Mansell Moullin presided. The treasurer's quarterly statement was of a satisfactory character. In the Benevolent Branch five applications for help were renewed for a further year, the total amount being £278. In the Relief Branch one new case and four old cases were renewed, and grants amounting to £130 were renewed. One new case was considered, and the school fees, amounting to £30, were granted. The next meeting of the committee will take place in October, when the majority of the cases are again reviewed.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal health statistics for 1923 of three county boroughs in the Lancashire and West Riding industrial area. Some of the characteristic features of a "mill" town are illustrated in the table—viz., a low birth-rate, a high neonatal and infant mortality-rate, and high death-rates from childbirth and respiratory diseases:—

Name of county borough.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Blackburn ..	129,000	16·2	13·4	1·0	1·4	3·6	47	100	6·7
Stockport ..	125,700	17·6	12·7	1·2	1·3	3·0	34	92	4·1
Halifax	99,840	15·2	13·8	1·0	1·5	3·0	47	90	6·6

Blackburn.

In his very complete account of the activities of the Blackburn Health Department for 1923, Dr. W. Allen Daley has noteworthy events to record, while we mentioned in THE LANCET of July 19th (p. 127) the general lessons in relation to the cotton industry. In May an empty pavilion at the Corporation Hospital, with a playing field adjoining, was opened as an open-air residential school for 20 pretuberculous children with very successful results. Accommodation has also been made at the hospital for a day open-air class. In February an X ray apparatus was installed at the hospital, and has been found very useful in the diagnosis of suspected cases of tuberculosis of the lungs and thoracic glands, and also in gauging the effects of pneumothorax treatment, which was tried for the first time during the year, with encouraging results. In March an orthopædic clinic was begun. Monthly sessions are held by Dr. W. Briggs. Of the 75 patients dealt with, 25 were admitted to the Queen's Park Hospital of the guardians for operative treatment through the Crippled Children's Aid Society, which also provided extra nourishment, splints, and surgical appliances, and sent children to their Holiday Home.

In November the Springfield Maternity Home was opened. This is the successor to a six-bed home, opened by the corporation in August, 1921 (in coöperation with the Blackburn District Nursing Association). the success of which indicated that a long-felt need was being met. The new home was adapted from a large house in the best part of the town with nearly two acres of grounds, and has accommodation for 20. In view of the high maternal mortality from childbirth a special effort was made at the end of the year to arouse the interest of the midwives in antenatal work by the issue to them of certificates of efficiency. During 1923 only 97 mothers attended the antenatal clinic, and of these one was sent by a doctor and four by midwives. The results of the new effort is shown by the fact that there have been 78 new antenatal cases in the first quarter of 1924. A special clinic has been established during the year at a maternity and child welfare centre for the treatment of infants infected with venereal diseases, and their mothers. The clinic is conducted by Dr. Ella G. F. Mackenzie. Dr. Daley records the fact that the 208 blind persons in the town do not include a single blind child under 5 years of age, although 35 of the adult blind have been blind from infancy. In April a week's intensive campaign of publicity regarding venereal diseases took place and was a great success, large audiences being obtained. As regards education on health, Dr. Daley has two suggestions to make. First, there is a great lack of suitable cinematographic films on health subjects, and he thinks some central body should concern itself with the production of such. Secondly, he thinks such a central body might produce a monthly or quarterly health bulletin, to which local additions might be made, as is done in the case of parish magazines.

---

[1] See THE LANCET, April 12th, 1924, p. 773.

Considerable efforts were made for the improvement of the milk-supply. The second clean milk competition for Alderman Fielding's Silver Cup was held from January to March. There were six entrants, all of whom reached a satisfactory standard. The unprogressive farmers held aloof or were actively hostile. Samples of milk from farms inside and outside the borough were examined for dirt. Of "inside" samples, 14 per cent. were grossly contaminated, and 8 per cent. were filthy. Of outside samples, 36 per cent. were grossly contaminated and 6 per cent. were filthy. Five out of 89 samples examined were found to contain living tubercle bacilli.

Stockport.

Dr. Arthur G. Jenner records two small outbreaks of scarlet fever. The one occurred in connexion with a private school, and probably originated with a mild unrecognised case of the disease. The other was traced to a milk-supply, the son of the milk vendor being among the patients. The milk in question came from an outside farm on which no source of infection was discovered, but there was a simultaneous outbreak in a neighbouring town, for which milk from the same district appeared to be responsible. The building of new houses shows some improvement. In 1923 176 new houses were built, and 125 more were in course of erection at the end of the year. The number built in previous years were: in 1918 and 1919, none; in 1920, 24; in 1921, 131; and in 1922, 71. The inspector found 21 tuberculous animals in the cowsheds, which were surrendered and destroyed. The examination of the mixed milk from six farms revealed one tuberculous sample and led to the destruction of one cow. No less than 32 of the 146 cases of tuberculosis which terminated fatally were unnotified at the time of death. The Stockport Corporation contract for beds at various sanatoriums —viz., 16 beds in the Cheshire Joint Sanatorium (recently opened), five beds at Wensleydale, and three at the Shropshire Orthopædic Hospital. They are also helped by the George Fearn Trust, which provides ten beds at the Ormerod Home, St. Anne's-on-Sea, for weakly and pretuberculous children. The same trust provides accommodation for weakly children at several farms in the vicinity of Stockport, with very beneficial results.

Halifax.

Dr. Cyril Banks discusses the high mortality from childbirth in view of Dr. Janet Campbell's recent report showing the bad position occupied by Halifax. He thinks that the increased facilities for admission to St. Luke's Maternity Home and the new maternity wards of the Royal Halifax Infirmary will be a step in the right direction, *provided* adequate medical supervision during the months of pregnancy can be insisted upon. He suggests that attendance at the antenatal clinic should be made a condition of admission to these lying-in wards. Such a condition is, we believe, already in force in the case of the lying-in wards of St. Thomas's and other hospitals with beneficial results. The Ministry has been asked to sanction the appointment of two additional health visitors in order to allow of increased antenatal visiting, better supervision of children from 1 to 5 years of age, an extension of tuberculosis visiting, and the transfer of the supervision of the mentally defective from the sanitary inspectors to the health visitors. Sanction has, however, only been given for one additional appointment. Tuberculosis after-care work is carried out in Halifax by a committee of the council of social welfare.

In her report on maternity and child welfare work, Dr. Alice Latchmore refers to the "handy-woman" difficulty. She also mentions that one "bona fide" midwife was removed from the Roll and a trained midwife censured for failing to call in medical aid in cases of ophthalmia neonatorum. Breast-feeding appears to be increasing; 60·5 per cent. of infants were breast-fed for six months in 1923, as compared with 54 per cent. in 1922. Dr. Banks is unable to report any appreciable improvement in the milk-supply. None of the special grades of milk designated in the Order of 1922 is on sale in Halifax. Halifax is evidently attacking the industrial smoke problem seriously, and a very interesting report is submitted by the smoke inspector, Mr. Herbert G. Clinch, whose book on the subject was recently reviewed in THE LANCET. The policy adopted in Halifax which is producing such satisfactory results is one of coöperation with owners and firemen, and many of the firms who have availed themselves of Mr. Clinch's expert advice have not only done away with the smoke nuisance, but have had the satisfaction of realising a considerable saving in fuel costs.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 19TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 42; scarlet fever, 1333; diphtheria, 694 (as against 654 of the previous week); enteric fever, 91 (as against 126 of the previous week); pneumonia, 570 (as against 497 of the previous week); puerperal fever, 26; cerebro-spinal fever 8; acute poliomyelitis, 27; acute polio-encephalitis, 1; encephalitis lethargica, 81 (as compared with 81 of the previous week); dysentery, 2; and ophthalmia neonatorum, 109. There were no cases of cholera, plague, typhus, or continued fever notified during the week. Of the 42 cases of small-pox, 8 were notified from the county of Derby (Chesterfield 3, Chesterfield R.D. 5), 1 from the county of Gloucester (Gloucester), 12 from Northumberland (Ashington), 4 from the county of Nottingham (Hucknall 3, Mansfield 1), 8 from Yorks, North Riding (Middlesbrough 5, Eston 3), 5 from Yorks, West Riding (Rotherham 4). Of the cases of encephalitis lethargica, 11 were notified from the County of London (Bermondsey 1, Bethnal Green 1, Camberwell 1, Greenwich 1, Hackney 1, Kensington 1, St. Marylebone 1, Shoreditch 2, Stepney 1, City of Westminster 1), 9 from the county of Durham (Sunderland 3, Sunderland R.D. 2), 14 from the county of Lancaster (Liverpool 5, Manchester 4), 8 from the county of Warwick (Birmingham 7, Nuneaton 1), 4 from Yorks, West Riding (Sheffield 2), and 1 from the city of York.

Deaths.—In the aggregate of the great towns there was a decrease of 174 in the total deaths for the week under review. In London the number of deaths from all causes decreased from 763 to 752, while the deaths from diphtheria numbered 8, as compared to 7, 5, and 9 in the preceding three weeks.

BLIND MASSEURS.—The fifth annual report of the Association of Certificated Blind Masseurs records continued progress during the year which ended on June 30th, and the executive council gratefully acknowledge the help which they have received from the President, Sir Robert Armstrong-Jones, from St. Dunstan's Hostel, and from the National Institute for the Blind. The Association now has 173 members, composed of 92 blinded soldier masseurs, 38 civilian masseurs, and 43 masseuses. They are practising in 42 districts of London, 72 provincial towns in England, Wales, Scotland, and Ireland, and in some of the principal towns in Australia, New Zealand, Canada, South Africa, and South America. The address of the Association is 224, Great Portland-street, London, W. 1.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

(Continued from p. 192.)

REPRESENTATIVE MEETING.

SATURDAY, JULY 19TH.

HOSPITAL POLICY OF THE ASSOCIATION.

As briefly noted in our report last week the afternoon session of this day was occupied with a momentous debate on the policy of the Association in regard to remuneration of the medical staffs of voluntary hospitals. It will be remembered that the subject was fully discussed at the representative meeting in 1923, when a motion to postpone decision was proposed by a member of the Council and passed by a small majority. The subject was now reintroduced on a motion by Mr. N. BISHOP HARMAN, (late) Chairman of the Hospitals Committee, to rescind para. 10 of the scheduled hospital policy as no longer applicable, and to substitute a new form of words fitting the new situation. The old paragraph runs :—

> Gratuitous contributions to hospitals by employers of labour or by employees should not be treated as the payment of premiums for insurance against the cost of maintenance and medical treatment for sickness or accident, nor as entitling the contributors to claim hospital treatment either for themselves or for persons nominated by them, but as charitable contributions to be expended at the discretion of those to whom the management of the hospital is entrusted.

Mr. Harman, on behalf of the Hospitals Committee, now proposed to substitute the brief declaration :—

> Contributions to hospitals by employers of labour or massed or periodical contributions by employees should be considered as contributions for services rendered or to be rendered.

Mr. Harman, in moving the resolution, spoke of the increasing interest which was being taken in hospital administration, as shown by the steady flow of inquiries he received. Recently they had been working in coöperation with the British Hospitals Association. During the past year a questionnaire had been issued to 912 hospitals in England and Wales in the following terms :—

Staff Fund Questionnaire.

1. Does the hospital enter into arrangements for the treatment of State, municipal, and similar patients—e.g., Ministry of Pensions, War Office, Board of Education, Ministry of Health, Admiralty, municipal or other local authority?

2. Do the members of the medical staff receive any form of remuneration in respect of above? If so, in what form? (a) Directly from the authority concerned? (b) Honorarium? (c) Staff fund?

3. Does the hospital receive payments from employers of labour, approved societies, or insurance companies in respect of patients?

4. Do the members of the medical staff receive any form of remuneration in respect of above? If so, in what form?

5. Does the hospital receive payment through a contributory scheme in which there is a stated return—e.g., contributory insurance scheme?

6. Do the members of the medical staff receive any form of remuneration in respect of above? If so, in what form?

7. Does the hospital receive payment through a contributory scheme in which there is an implied return—e.g., workers' mass or periodical contributions?

8. Do the members of the medical staff receive any form of remuneration in respect of above. If so, in what form?

9. Is there any system of inquiry into the means of each patient?

Nearly one-half of the hospitals had responded with information, from which it appeared that (1) of 237 hospitals entering into arrangements for the treatment of State, municipal, and similar patients, in 73 per cent. some remuneration was being paid to the medical staff; (2) of 217 hospitals receiving payments from employers of labour, approved societies, or insurance companies, in 7 per cent. some remuneration was paid; (3) of 62 hospitals receiving payments through contributory schemes with stated return, in 11 per cent. some remuneration was paid: (4) of 110 hospitals receiving payments through contributory schemes with implied return, in 11 per cent. some remuneration was being paid to the medical staff. Taking the four categories together, the inquiry showed that in 25·6 per cent. of hospitals some form of pecuniary recognition was already being made to members of the medical staff.

Capital Value of Staff Services.

The Hospitals Committee, Mr. Harman went on, desired to find conditions that would cover all circumstances, from those of the little cottage hospital to those of the teaching hospital. The keynote of their policy was that it was never in the imperative mood; it was always in the persuasive mood. When the policy of the Association was expounded to hospital administrative officers he found that they were not in the least hostile, but recognised that the principles were fair and just, although at the moment funds might not permit of any such change. The work of hospital staffs was often eulogised, but few people, he thought, fully realised its value to the community at large. A former chairman of that representative meeting calculated that at his hospital at Cardiff the work of the staff was worth £350,000 a year to the community: on the same basis the cash value of the work of the medical staffs of hospitals in England and Wales worked out at £54,000,000 a year. His belief was that voluntary hospitals to-day were better than ever they had been, and that they were destined to be better still. The Association was striving to secure a succession of men, who would carry on the work as their fathers did. He reminded them of the "bidding prayer" heard when the Association met at Cambridge, and said he would like to make a medical version of it: "That there may never be wanting a succession of skilful and devoted men to serve God and the nation in the hospitals of this country, let us work to establish a sure foundation and defence for the generations that are to come." It was wrong that large sums paid to hospitals by friendly societies and large industrial undertakings should come in under the old para. 10. Para. 10 as it stood was effete, and should be replaced by something that met the situation to-day.

A Vote on the Principle.

In the discussion that followed the Chairman allowed individual members a very wide liberty, as he said, "to let off steam." It was argued on the one side that to pass this resolution would make difficulty by involving medical staffs of hospitals in a definite contract which they would be bound to fulfil; that the staff under the voluntary system could not expect all the advantages of State or municipal officers ("if you want salaries say so, but you will cease to be honorary officers"); that in Scotland, at all events, there was no lack of competition for honorary positions, successful applicants well knowing that in the fulness of time there would be a much larger return than in general practice. On the other side it was pointed out that voluntary hospitals now contained only 5 to 10 per cent. of the class for whom they were originally intended: that when a business firm contributed £1000 a year to a hospital it meant "we expect you to look after our staff": that five guineas a week was now quite a usual charge to hospital patients, and that working men when they realised the situation would themselves prefer to pay the staff a fair wage for a fair day's work. All that could be said on the one side or the other was said and well said. The voting on the resolution was taken by roll-call, when there were 87 ayes, 19 noes, and 12 abstentions. The requisite two-thirds majority not being obtained, the Chairman stated that the motion was a resolution by the Representative Body and not a declaration of policy of the Association.

Taxing of Massed Contributions.

In proposing the next resolution Mr. HARMAN asked the meeting to bear in mind the various categories in which payments received by hospital authorities on behalf of patients were made. The representative meeting had already defined its policy in regard to contributions received under contract between the hospital and an employer (the State, a statutory authority, or an insurance committee) on behalf of persons for whom it was responsible. That was the highest form of arrangement by which payments were made to a hospital. A second form was where a third party contributed towards treatment without actual contract. A third form was where the patient or his friends paid for what was done for him. It had been agreed times out of number that when there was a contractual arrangement of the first category some portion of that money should be credited to the staff, and it had also been agreed that this was to be done through the staff fund. The position was not quite so clear as to how contributions made by approved societies or contributory schemes should be treated. Several members of his committee were in favour of the recognition of staff services, but not through staff funds for local reasons which made it difficult. It had been suggested, therefore, that the remuneration could be either in the form of an agreed honorarium or through a staff fund.

After discussion on familiar lines, during which the phraseology of the resolution was modified to meet various objections, it was put and carried thus:—

> Where the board of management of a voluntary hospital accepts contributions for patients from an approved society, insurance company, contributory scheme, employer of labour, and/or by massed or periodical payments by employees, the members of the visiting medical staff should receive recognition of their services either in the form of an agreed honorarium, or by means of a percentage of all such payments being passed into a fund. Such honorarium or fund can be allocated in any manner which the visiting medical staff may determine.

Monday, July 21st.

Taxing of Individual Payments.

The principle of payment of hospital staff was carried a stage further by a resolution proposed on behalf of the Hospitals Committee by Mr. **Harman**:—

> Where the board of a voluntary hospital accepts payments from individual patients [other than paying patients referred to in Sections IX. (*a*) and IX. (*b*)] the members of the visiting medical staff should receive recognition of their services either in the form of an agreed honorarium or by means of a percentage of all such payments being passed into a special fund. Such honorarium or fund can be allocated in any manner which the visiting medical staff may determine.

This resolution, said Mr. Harman, was the keystone of the arch of the Association's hospital policy. Unless that resolution were carried the whole fabric would gradually fall in. This policy would protect all and sundry from being tempted to do that which was not quite straight. Unless this resolution were on the books, requiring some form of assessment of payments by individual patients, inevitably it meant that all those patients sent by the State, all those sent by employers of labour or under contributory schemes of approved societies and insurance companies, would be required to make their own arrangements; they would be sent to the hospital and told to pay the charges of the institution, and when they returned to their homes the thing would be squared up as between the patient and the approved society or other body.

Mr. Harman believed that this resolution made for justice and equity as between different classes of the community. To-day a large proportion of the work of those consultants who were attached to hospitals was given without any remuneration whatever. It had been said by one consultant that three-fourths of his work was done free. That meant that the consultant was charging all the cost of that three-fourths of his work to the remaining quarter of his patients—"the Robin Hood method," Mr. Harman called it. But the manual worker in these days was not a helot; he had a good time, thanks to what the brain-worker had done for him. At the moment the boot was on the other foot; the brunt fell on the brain-worker, whose wages had not increased in proportion to those of the manual worker. By this method of making all the costs of the consultant fall on a quarter of his patients they were causing the brain-workers to pay for the hospital treatment of the manual worker. If this were put to the manual worker he would say at once that it was not fair and that he did not want it.

Payment not "Repugnant."

On an amendment by Bolton that such taxation of voluntary payments by individual patients was repugnant to the hospital staffs, Dr. J. C. **Matthews** pointed out the possibility of a hospital charging its patients enough to carry on without the aid of voluntary contributions at all, and the absurdity then of an unpaid staff. Dr. P. **Macdonald** created amusement by including himself among the number of those who had a subconscious vested interest in voluntaryism. He did a large part of his work at hospital, and made his living by charging those people who were unfortunate enough to have to consult him larger fees than they could afford. From the South it was pointed out that the staff fund suggestion was terribly disliked, and if pushed would lead to withdrawal from membership. The amendment was lost by a large majority.

"Not Recoverable from Third Parties."

An amendment was then proposed by Dr. E. R. **Fothergill** (Brighton) to exclude from the scope of the resolution payments which could be recovered from third parties:—

> Where the board of a voluntary hospital accepts payments from individual patients [other than paying patients referred to in Sections IX. (*a*) and IX. (*b*)] *not recoverable from third parties* which are insufficient to pay more than the total average cost to the hospital, such payments shall not be liable for assessment for visiting medical staff fund purposes; but some form of recognition should be made to the visiting medical staff from all other such payments by way of an agreed percentage in the case of a public authority, and by an honorarium or otherwise in all other instances.

Dr. Fothergill spoke of the differing conditions in North and South; in the North the taxing of individual contributions might be necessary to avoid exploitation, in the South it would be considered mercenary by many. In any case, it would be wiser to postpone decision since hospital benefit was likely to be brought by the Royal Commission within the National Insurance scheme. Mr. W. **McAdam Eccles** explained how the antagonism to medical staff funds was disappearing in London. One reason for this was that members of voluntary hospital staffs who had been receiving an honorarium in respect of their motor-car or telephone had had to concede that they were receiving that honorarium out of the ordinary funds of the hospital. Secondly, payment up to a "maintenance" limit was not necessarily "voluntary"; there were some hospitals which laid it down that payment "must" be made. And finally, there was another consideration which counted for much. The majority of patients did actually believe that the payments they made to the hospital, either voluntarily or on request, were made for two specific purposes—namely, partly for their maintenance in hospital and partly for the treatment they were receiving. Therefore they were right in asking for a proportion to be handed over to the medical staff fund. Mr. F. C. **Pybus** (Newcastle) said that the hospitals in the North must safeguard themselves against mass contributors, and that owing to increasing decentralisation the surgeon would have to look more and more to the hospital for his livelihood. Dr. **Christine Murrell** (London) called it almost unfair to the patient who paid a contribution to a hospital not to allow some portion of it to go to the doctor. She was sure the manual worker did not wish his treatment to be paid for by the brain-worker. Dr. T. W. **Lipscomb** (New South Wales) was afraid that if the resolution was carried it would be found to embarrass the profession overseas. Some of them who had had experience of Labour Governments felt that the best way to avert nationalisation of hospitals—which they did not want—was the retention of their status as honorary officials. He would restrict admittance to the actual "sick poor"—those unable to obtain adequate attendance in their own homes, when the urgency would disappear. Dr. E. W. G. MASTERMAN remarked that in all Government institutions the term "maintenance" included the salaries of the medical staff. Dr. N. MACFADYEN (East Herts) said that if that resolution were carried it meant that in theory, at least, the voluntary system was dead, and they were no longer free agents. Theirs was essentially a charitable profession. A large element in the country could not pay a proper amount for treatment, and until that portion of the population was in a better position it should be assisted by the charity of the public and to some extent by the charity of the medical profession. Dr. J. D. COMRIE said that in Edinburgh also there had been a change of view on the part of the hospital medical staffs. In the ordinary hospitals they were no longer dealing with the "sick poor"—who were to be found in the Poor-law infirmaries—but with the well-to-do artisan class who were able, and often anxious, to contribute to the hospital. Dr. C. BUTTAR agreed with Australia; it was not good tactics to fight Labour control by taking Labour money. Mr. SOUTTAR thought the adoption of the resolution would render the whole hospital policy nugatory. It was almost impossible to ascertain whether the payments of patients were personal or not. It had been suggested that a way out of the difficulty would be to limit hospital admission to hospitals to the "sick poor," but they had no right to do that. How many nursing homes in the country were equipped with X ray apparatus? What right had they to exclude those who had put by a little money and who stood in need of treatment which could only be obtained at a hospital?

Dr. Brackenbury Sums Up.

We have reported at some length the discussion on Dr. Fothergill's amendment, for it was the final stage in what no doubt will come to be regarded as an historic decision, and all shades of opinion were well represented and clearly expressed. Before Mr. Harman replied for the Hospitals Committee, Dr. BRACKENBURY set out with admirable precision the essential elements of the situation. The point, he said, they had to decide was whether personal contributions from patients which did not reach the level of the cost of maintenance ought or ought not to be ear-marked for contributions to the State fund. He had previously spoken on the side of those who thought that such a contribution ought not to be so ear-marked. Like Sir Richard Luce, he had been converted. In the first place, the hospitals were in a better financial position than they were two years ago, and he did not think medical men would be so liable to be accused of putting into the pockets of the profession something which the hospitals desperately needed in order to enable them to carry on at all. Then the proposal now put forward was that there should be "an agreed honorarium," which was a very different thing from saying that 20 per cent. should be passed into the staff fund. That was one of the things which had enabled him to come round to its support. But he had also been impressed by the volume of evidence that had come to him, especially from the North of England, that there was a great deal of subterfuge actually going on in this matter. There were societies and employers and combinations of workpeople who were sending people into hospitals and saying: "We will let you pay the subscription to the hospital and we shall then be able to get off without paying this contribution to the staff." He therefore thought it dangerous to draw a line between massed contributions and individual contributions. Then there were many people who could contribute something above the cost of maintenance and did, in fact, contribute something below the cost of maintenance. He was convinced that the distinction between a personal contribution above the cost of maintenance and one not above the cost of maintenance was impracticable to obtain. He doubted if the motion in fact did what its proposer intended it to do. The motion read "not recoverable from third parties." He did not see how it could be discovered in individual cases all over the country whether a contribution given was or was not recoverable from, or provided by, somebody else. If that could not be discovered, then it was better to have the simple clear-cut policy—that all these contributions should be ear-marked in some way, and to some degree, as a recognition of the services of the hospital staff, even if in a particular hospital the staff desired only a nominal honorarium which they could give back to the hospital if they liked.

Mr. HARMAN said that the policy was not intended to apply to Australia, where there were four different classes of hospital—known as departmental, committee, intermediate, and private—which did not correspond in essential ways to conditions in Britain. The Brighton amendment having been put to the meeting and lost by a large majority, the resolution was carried by the necessary two-thirds majority and becomes the policy of the Association.

"Super-Contributory" Schemes.

Mr. HARMAN then suggested that in the event of proposals being made to establish contributory schemes to provide in-patient treatment for those referred to in the hospital policy of the Association as "private patients" and yet who are unable to pay individually at the time of illness for these benefits, such schemes shall provide as follows:—

(*a*) An income limit scale such as is approved by the majority of the medical profession resident and practising within the area of the scheme.

(*b*) The accommodation provided for in-patient treatment to be at recognised nursing homes, paying hospitals, or in accommodation of the nature of a nursing home in connexion with a voluntary hospital.

(*c*) Patients should be admitted to the benefits of the scheme only on the recommendation of a private practitioner, except in cases of emergency.

(*d*) Free choice of doctor (attendant and specialist) by the patient subject to the consent of the doctor to act.

(*e*) The scheme to be administered by a general committee representative of all the interests concerned—medical, hospital, and lay—and not by any voluntary hospital or other coöperating institution.

(*f*) The method of remuneration of medical specialists to be payment for work done on the terms customary for such patients in each area.

(*g*) Any provision made under such schemes for consultation and specialist's services apart from in-patient treatment shall be arranged for at the consulting rooms of the chosen consultant or at the home of the patient on terms customary for such patients in the area of the scheme, and not in any out-patient department of any institution.

This proposal was carried without further discussion.

Standards of Hospital Provision.

Mr. HARMAN then suggested that it would be well for the Association to lay down certain approved standards for hospitals in England and Wales, with 100 or more beds, on the basis of the information obtained by the Hospitals Committee. And with very little hesitation the following standards were accepted:—

(*a*) In every such hospital the visiting staff should be of recognised competency and should be proportionate to the number of beds in the hospital: a suitable ratio is about 1 to every 25 beds, or where out-patient departments exist the ratio of staff should be greater.

(*b*) In every such hospital recognised arrangements should exist for obtaining the services of registered practitioners experienced in (*a*) anæsthesia; (*b*) dental surgery; (*c*) dermatology; (*d*) diseases of the ear, nose, and throat; (*e*) electrology; (*f*) gynæcology; and (*g*) ophthalmology.

(*c*) In every such hospital there should be recognised departments for radiology, medical electricity, and massage.

(*d*) In every such hospital there should be provision, wherever useful and possible, for the services of clinical assistants.

(*e*) In every such hospital there should be at least one resident officer to every 50 beds.

(*f*) In every such hospital there should be staff meetings for discussion of clinical work at least once a month, and an analysis of the hospital work should be presented at each meeting.

(g) Every such hospital should have an efficient clinical laboratory with a recognised pathologist in charge.

(h) In every such hospital case records should be kept in respect of every patient, and these should be signed by the member of the staff responsible for the case; these records should be filed and indexed by a competent clerk; every effort should be made to obtain the subsequent medical history of each patient.

(i) There should be exchanges of information between the patient's medical attendant and the hospital medical staff.

Note.—To all letters issued by medical members of hospital staffs the following note should be appended: "The information contained in this letter is strictly private and confidential to the person to whom it is addressed, and must not be divulged without the consent of the writer."

(j) Every such hospital should employ a registered pharmacist.

(k) Every such hospital should be a recognised training school for nurses, and should have, or be associated with, a preliminary training school.

Formation of Local Hospital Committees.

The last act of the retiring chairman of the Hospitals Committee was to propose a scheme for the formation within the Association of local hospital committees for the purpose of organising local professional opinion as to hospital medical service. These committees, elected half by members of hospital staffs and half by the branch council, are to consider all arrangements made in connexion with local hospital conditions and all disputes arising in connexion therewith. The proposal was accepted without discussion, and Mr. Harman on leaving the platform received warm congratulation on the conclusion of his work.

TUESDAY, JULY 22ND.

AFFILIATION OF THE CANADIAN MEDICAL ASSOCIATION.

On behalf of himself and his co-delegate, Dr. Alfred Cox, Sir T. **JENNER VERRALL** presented a report on their Canadian mission. In Canada the Association had never, for some reason or another, had the same hold on the profession that it had had in other parts of the Empire. Two successful annual meetings had been held, one at Montreal in 1897, the other at Toronto in 1906, but at the present time, out of a medical population of about 9000 in Canada, there were only 374 members of the British Medical Association, and the five branches existed only on paper. In these circumstances the suggestion of a possible affiliation led to a warm invitation from the Canadian Association to send delegates to discuss the question, accompanied by a pressing invitation to hold the annual meeting of the Association at Winnipeg in 1927. The mission found on the part of the Canadian medical profession an extreme readiness to accept a proposal for affiliation. Meetings were held at Quebec, Montreal, Toronto, and Ottawa, where the desire for closer union was explained and a scheme of affiliation formally adopted by the Canadian Association. Affiliation, he recognised, was in no sense an equivalent to membership in the British Association, but it gave an opportunity for coöperation, for reciprocal visits, and for tendering advice as medical policy developed in Canada.

Dr. **COX** spoke of their reception in Canada, where they were almost killed with kindness. The meeting endorsed the report, thanking the delegates for their services, and on the suggestion of the Chairman a message was sent by the meeting to the Canadian Medical Association expressing pleasure that the twenty-first meeting of the Representative Body should have been marked by the setting in motion of a scheme for closer relationship with their Canadian brethren.

INDIRECT ADVERTISING.

ON behalf of the Central Ethical Committee Dr. R. L. **LANGDON-DOWN** (South Middlesex), chairman of the Committee, moved the adoption of the very careful report on Indirect Methods of Advertising which we reproduce at length on page 246. Dr. Langdon-Down began by defining the two possible attitudes in regard to advertisement by medical men. Either complete freedom could be given or certain restrictions could be enforced by professional opinion or by professional law. He regarded the discountenancing of advertising methods as specially desirable on grounds of public interest. The basis of professional reputation should not be the self-praise of the individual, nor the appreciation of those who were poorly qualified to judge or who based their approval on unworthy or biassed grounds, nor should it depend on the frequency of the appearance of the practitioner's name in the public press, with or without photograph and appropriate headlines. Professional reputation should be soundly based on the esteem of colleagues and on solid, quiet work. Restrictions if made must of course be applied all round, and he went on to outline the relations of the Association with the General Medical Council and the more searching character of the Warning Notice issued as a result of their representations and Dr. Bolam's intervention in the Council. The policy of the Association was to treat the subject of advertising as a live part of professional law with no distinction between practitioner and consultant, and they had tried to harmonise the new law against indirect advertising with the exigencies of life and practice. The principle was easy, the application difficult; and he besought the meeting at all events to accept the general policy laid down in the report.

Dr. **FOTHERGILL** moved an amendment that, in view of no distinction being made in the report between intra- and extra-professional advertising, it should be referred back to the Committee for revision. They were all heartily in favour of something being done to stop the blatant kind of advertisement that was going on, and his own wish was to ask the press to coöperate. The reputable press did not want to advertise the inferior practitioner but it did sometimes desire to have adequate medical opinion on a matter of importance. If, he said, you allow a doctor to talk openly of birth control at a Church Congress, why not allow him an article over his own name in the public press? The public could see no distinction. The report suggested that a statement without signature would be of equal value. But was it? Certainly, readers would regard it as coming with more weight from Dr. So-and-So. The alternative would be for the Association itself to arrange for the issue of efficient statements on questions of moment, the information to be given in the name of the local division and not in the name of any individual. Should the ethical question then be raised, the Association would be in a position to say to the individual doctor: "Your opinion is not required: we have a scheme to inform the public adequately."

Dr. **BRACKENBURY** agreed that an anonymous letter did not in fact carry the authority of one that was signed. In this respect the report would have either too much effect or none at all. On important occasions they had agreed that certain doctors should write to the press. The iniquity consisted not in the name but in the address and photograph. Journalists were naturally apt to look at the matter not from the point of view of the medical profession but from their own, and they would put in your photograph ("or some one else's, with your name under it") without consulting the writer. "Some of us," he said, "suffer; but some of us do not mind. Personally, I suffer." He hoped that this part of the report would be referred back for consideration.

Dr. P. **MACDONALD** concurred, for he believed that on this point they would not carry the public with them.

Sir **JENNER VERRALL** regarded Dr. Fothergill's suggestion as impracticable. It was a question of speed. Answers would not be obtained in time from the division, and in the long run the public would remain unsatisfied. It was hardly correct to suggest that the medical man was tempted by the press; "what he does he does for his own advantage." The General Medical Council could not lay down any strict letter of law, but it was equivalent to a jury of common-sense men who could decide in a particular case whether that was the kind of thing the medical man ought to have done. It should be possible to check erring brethren without depriving the public of legitimate information.

Dr. Langdon-Down was glad that no serious attack was made on the principles enunciated; Dr. Fothergill was in fact wanting the same thing as the framers of the report. Advertisement consisted of two parts—the act and the motive; it had been their endeavour to direct motives and to leave the General Medical Council to deal with practice. Where information, he said, is a question of fact, it matters not who writes it; only as an opinion did the name matter. In examining books on semi-medical topics the Ethical Committee always required that neither address nor portrait should appear and discouraged the elaboration of appointments and titles. But he was quite willing to take the paragraph back for consideration,

Dr. Bolam, as chairman of the B.M.A. Council, asked for endorsement or the reverse of the report as a whole. There was not merely passive resistance to encounter but actual defiance of what they thought was the proper professional ethic.

Mr. Bishop Harman described the report as good in the main, but impracticable and wrong in one particular. Surely the weight of a communication was in proportion to the personality behind it. An anonymous letter might readily fail of its effect. He recalled the incident of a brilliant letter addressed to the *Times* over the signature "Veritas" which made scarcely a ripple on the surface. "I wrote a letter and signed it with my own name," he said, "and it went to Hongkong and back." "If I read in a paper 'on eminent medical authority,' I turn the page at once, and so does the intelligent part of the public." There was a celebrated saying that in a speech three things mattered: what is said; how it is said; and who says it—and the last was the only thing that really mattered. It was much the same with articles and interviews. What was the good of a love letter if it was not signed?

After a very full discussion the meeting expressed agreement with the report as a whole, referring back for further consideration the section relating to the discussion in the papers of matters of public interest by letter, article or interview.

Election of Eight Members of Council.

Eight members of the Council were elected by representatives on the principle of the single transferable vote, the names being Dr. H. G. Dain, Mr. W. McAdam Eccles, Dr. E. R. Fothergill, Dr. R. L. Langdon-Down, Dr. J. A. Macdonald, Dr. G. W. Miller, Dr. C. Sanders.

ANNUAL GENERAL MEETING.

TUESDAY, JULY 22ND.

The annual general meeting was held in the Technical College at 2 P.M., when the outgoing President, Mr. C. P. Childe, inducted Mr. J. Basil Hall into the presidential chair and invested him with the badge of office. After the statutory business the President reported that Dr. F. G. Thomson, consulting physician to the Royal Mineral Water Hospital, Bath, had been elected President of the Association for the year 1925-26, in place of the late Mr. Forbes Fraser. Dr. Bolam proposed a vote of thanks to the retiring President. Not often, he said, had the Association enjoyed a President who entered so keenly and in such detail into its work, or one who found time in a busy life for so much civic activity. Mr. Childe, in responding, remarked that his year of office had been of great educational value to him; it was a pity that all members could not become presidents. He reviewed his year of office with special mention of the large amount of voluntary work done by members of the Council. At the evening adjournment in the Regent Picture House, attended by members in academic and official dress, the President was accompanied on the platform by the Lord Mayor of Bradford, the Archdeacon of Bradford (Canon Stanton Jones), and other prominent citizens. He welcomed the delegates from Overseas, introduced to him by Dr. W. N. West Watson, local general secretary. Among these were:—

Major J. Morison, I.M.S. and Dr. R. Row (Bombay), Dr. A. N. Coomarasamy (Ceylon), Dr. O. Marriott (Hong-Kong), Dr. A. C. Lankester (Hyderabad). Dr. K. A. W. Procter (Kenya), Dr. A. L. Hoops and Sir Malcolm Watson (Malaya), Dr. Gordon W. Spencer (Mesopotamia), Dr. A. J. Spiller Brandon and Dr. Norman Dowling (N.S.W.). Dr. J. A. Doctor, Dr. A. W. Izard. Dr. W. B. Mercer, Dr. P. T. Putnam (N.Z.), Mr. P. N. Yellacott (Orange Free State), Dr. R. F. Matters (South Australia). Dr. J. B. Davey (Tanganyika). Dr. T. W. Sinclair (Victoria), Dr. J. J. Holland (Western Australia), Dr. L. G. Irvine, and Dr. J. H. Harvey Pirie (Witwatersrand).

Dr. Bolam then handed the *Stewart Prize* of the Association to Dr. Edward Mellanby, professor of pharmacology in the University of Sheffield, for important discoveries in the relation between rickets and dietetic deficiency. The President remarked on the appropriateness of the presentation in Bradford, which was the first city to set the feeding of school children on a municipal basis. The *Gold Medal* of the Association was then handed by the President to Dr. H. B. Brackenbury, chairman-elect of the Representative Body, for arduous and distinguished services to the Association and the medical profession. The testimonial was inscribed in an illuminated album. Mr. Hall spoke of Dr. Brackenbury's services to the medical profession in the controversy regarding panel practice, recalling the admiration expressed by the Government Advocate for the moderate and public-spirited manner in which Dr. Brackenbury conducted his case.

The President then delivered the address which appeared at the front of the last issue of THE LANCET, and, this done, the guests adjourned to a reception in the spacious rooms of the Cartwright Hall, where the forecourt was tastefully illuminated, and a very pleasant social evening was spent.

THE ANNUAL DINNER.

The annual dinner was held at the Midland Hotel on Thursday, July 24th, Mr. J. Basil Hall presiding. After the loyal toast had been honoured, the President handed to Dr. J. Henderson (Glasgow) the Ulster cup, and to Dr. J. J. Buchan, medical officer of health for Bradford, the Childe cup, both won on the Hawksworth Links. Dr. Brackenbury, in proposing "The City of Bradford," said that there was more in civic life than mere comforts. The health of a town depended to a large extent on the city fathers. And just as the medical profession should not go outside its professional sphere and interfere in activities not theirs, so it would be a lamentable thing for a big corporation to ride rough-shod over the beliefs and traditions of the practitioners in the town. Only by active and willing coöperation could the health of a city be effectually secured. Sir William Priestley, in replying, pictured the changes seen during the last 50 years in the conditions under which the people lived and worked in Bradford. Archdeacon Stanton Jones proposed "The British Medical Association," remarking that the physical and spiritual realms were drawing closer, and it was difficult to say where the work of one began and the other ended. He hoped the day would never come when the doctor became a State official, and he trusted the Association would put its strength on the side of the righteous forces of the nation. Dr. Bolam, in replying, said they were prepared to place their experience and knowledge at the service of any political party in office which took (*g*) Every such hospital should have an efficient clinical laboratory with a recognised pathologist in charge.

(*h*) In every such hospital case records should be kept in respect of every patient, and these should be signed by the member of the staff responsible for the case; these records should be filed and indexed by a competent clerk; every effort should be made to obtain the subsequent medical history of each patient.

(*i*) There should be exchanges of information between the patient's medical attendant and the hospital medical staff.

Note.—To all letters issued by medical members of hospital staffs the following note should be appended: "The information contained in this letter is strictly private and confidential to the person to whom it is addressed, and must not be divulged without the consent of the writer."

(*j*) Every such hospital should employ a registered pharmacist.

(*k*) Every such hospital should be a recognised training school for nurses, and should have, or be associated with, a preliminary training school.

Formation of Local Hospital Committees.

The last act of the retiring chairman of the Hospitals Committee was to propose a scheme for the formation within the Association of local hospital committees for the purpose of organising local professional opinion as to hospital medical service. These committees, elected half by members of hospital staffs and half by the branch council, are to consider all arrangements made in connexion with local hospital conditions and all disputes arising in connexion therewith. The proposal was accepted without discussion, and Mr. Harman on leaving the platform received warm congratulation on the conclusion of his work.

TUESDAY, JULY 22ND.

AFFILIATION OF THE CANADIAN MEDICAL ASSOCIATION.

On behalf of himself and his co-delegate, Dr. Alfred Cox, Sir T. JENNER VERRALL presented a report on their Canadian mission. In Canada the Association had never, for some reason or another, had the same hold on the profession that it had had in other parts of the Empire. Two successful annual meetings had been held, one at Montreal in 1897, the other at Toronto in 1906, but at the present time, out of a medical population of about 9000 in Canada, there were only 374 members of the British Medical Association, and the five branches existed only on paper. In these circumstances the suggestion of a possible affiliation led to a warm invitation from the Canadian Association to send delegates to discuss the question, accompanied by a pressing invitation to hold the annual meeting of the Association at Winnipeg in 1927. The mission found on the part of the Canadian medical profession an extreme readiness to accept a proposal for affiliation. Meetings were held at Quebec, Montreal, Toronto, and Ottawa, where the desire for closer union was explained and a scheme of affiliation formally adopted by the Canadian Association. Affiliation, he recognised, was in no sense an equivalent to membership in the British Association, but it gave an opportunity for coöperation, for reciprocal visits, and for tendering advice as medical policy developed in Canada.

Dr. COX spoke of their reception in Canada, where they were almost killed with kindness. The meeting endorsed the report, thanking the delegates for their services, and on the suggestion of the Chairman a message was sent by the meeting to the Canadian Medical Association expressing pleasure that the twenty-first meeting of the Representative Body should have been marked by the setting in motion of a scheme for closer relationship with their Canadian brethren.

INDIRECT ADVERTISING.

ON behalf of the Central Ethical Committee Dr. R. L. LANGDON-DOWN (South Middlesex), chairman of the Committee, moved the adoption of the very careful report on Indirect Methods of Advertising which we reproduce at length on page 246. Dr. Langdon-Down began by defining the two possible attitudes in regard to advertisement by medical men. Either complete freedom could be given or certain restrictions could be enforced by professional opinion or by professional law. He regarded the discountenancing of advertising methods as specially desirable on grounds of public interest. The basis of professional reputation should not be the self-praise of the individual, nor the appreciation of those who were poorly qualified to judge or who based their approval on unworthy or biassed grounds, nor should it depend on the frequency of the appearance of the practitioner's name in the public press, with or without photograph and appropriate headlines. Professional reputation should be soundly based on the esteem of colleagues and on solid, quiet work. Restrictions if made must of course be applied all round, and he went on to outline the relations of the Association with the General Medical Council and the more searching character of the Warning Notice issued as a result of their representations and Dr. Bolam's intervention in the Council. The policy of the Association was to treat the subject of advertising as a live part of professional law with no distinction between practitioner and consultant, and they had tried to harmonise the new law against indirect advertising with the exigencies of life and practice. The principle was easy, the application difficult; and he besought the meeting at all events to accept the general policy laid down in the report.

Dr. FOTHERGILL moved an amendment that, in view of no distinction being made in the report between intra- and extra-professional advertising, it should be referred back to the Committee for revision. They were all heartily in favour of something being done to stop the blatant kind of advertisement that was going on, and his own wish was to ask the press to coöperate. The reputable press did not want to advertise the inferior practitioner but it did sometimes desire to have adequate medical opinion on a matter of importance. If, he said, you allow a doctor to talk openly of birth control at a Church Congress, why not allow him an article over his own name in the public press? The public could see no distinction. The report suggested that a statement without signature would be of equal value. But was it? Certainly, readers would regard it as coming with more weight from Dr. So-and-So. The alternative would be for the Association itself to arrange for the issue of efficient statements on questions of moment, the information to be given in the name of the local division and not in the name of any individual. Should the ethical question then be raised, the Association would be in a position to say to the individual doctor: "Your opinion is not required: we have a scheme to inform the public adequately."

Dr. BRACKENBURY agreed that an anonymous letter did not in fact carry the authority of one that was signed. In this respect the report would have either too much effect or none at all. On important occasions they had agreed that certain doctors should write to the press. The iniquity consisted not in the name but in the address and photograph. Journalists were naturally apt to look at the matter not from the point of view of the medical profession but from their own, and they would put in your photograph ("or some one else's, with your name under it") without consulting the writer. "Some of us," he said, "suffer; but some of us do not mind. Personally, I suffer." He hoped that this part of the report would be referred back for consideration.

Dr. P. MACDONALD concurred, for he believed that on this point they would not carry the public with them.

Sir JENNER VERRALL regarded Dr. Fothergill's suggestion as impracticable. It was a question of speed. Answers would not be obtained in time from the division, and in the long run the public would remain unsatisfied. It was hardly correct to suggest that the medical man was tempted by the press; "what he does he does for his own advantage." The General Medical Council could not lay down any commending or directing attention to the practitioner's professional skill, knowledge, services, or qualifications, or depreciating those of others; or of being associated with or employed by those who procure or sanction such advertising or publication, and

(b) Of canvassing or employing any agent or canvasser for the purpose of obtaining patients; or of sanctioning or of being associated with or employed by those who sanction such employment;

are in the opinion of the Council contrary to the public interest and discreditable to the profession of medicine, and any registered medical practitioner who resorts to any such practice renders himself liable on proof of the facts to have his name erased from the Medical Register.

The Newer Methods of Advertising.

Examples of the newer methods are to be found in interviews granted to newspaper representatives, and in signed letters or articles sent to newspapers. In many of these, members of the profession, either by the direct assertion of the journalists concerned, or by more indirect methods, are referred to as possessing, or allow it to be inferred from their own words that they possess, methods of treatment superior to those practised by others. In the opinion of the Committee the word "advertising" in connexion with the medical profession must be taken in its broadest sense, to include all those ways by which a person is made publicly known, either by himself, or by others without his objection, in a manner which can fairly be regarded as "for the purpose of obtaining patients or promoting his own professional advantage."

Accepted Customs.

It is generally accepted by the profession that certain customs are so universally practised that it cannot be said that they are for the person's own advantage, as, for instance, a door-plate with the simple announcement of the doctor's name and profession. Even this, however, may be abused by undue particularity or elaboration.

Intra-Professional Channels.—It is commonly agreed that channels must be open for discussion between members of the profession for recording the results of research and clinical experience and for bringing to the notice of other members books published and facilities for treatment offered. The recognised channels are medical societies, medical periodicals, and works primarily intended for the medical profession. The information so given is intended for the convenience and advantage of the profession, which will be in a position to judge of the value of the information and of the manner in which it is conveyed. Even this legitimate kind of advertisement is capable of abuse.

The Medical Man as Citizen.—It is the recognised duty and right of a medical man to take his share as a citizen in public life, but there is no reason why this should involve any advertisement of himself as a doctor, and, with due care, improper advertisement can be avoided.

Publicity as an Official Duty.—Publicity is rightly allowed to medical men not in actual practice of their profession since they cannot be regarded as using this publicity for the purpose of promoting their own professional advantage, and in view of the official position of medical officers of health and other medical men who hold posts in either the public health or other public service, publicity is sometimes not only permissible but necessary for the fulfilment of their official duty. The presumption in all these cases is that publicity is not sought for the individual's own gain though it is possible that the practice might be abused and the presumption therefore fail. [illegible]

Books and Lectures.—The publication of books and the delivery of lectures on semi-medical topics which are of general public interest and require medical knowledge for their proper presentation have been recognised as legitimate, subject to the avoidance of methods which tend to the personal professional advantage of their authors. There are many things innocent in themselves which may, by the manner and frequency of their doing, gravely contravene the principle that medical practitioners should not advertise.

Letters to the Press: Signed or Unsigned.

From time to time there are discussed in the papers matters of great public interest or importance regarding which it is to the advantage of the public that the medical considerations involved should be stated either by letter, article, or interview. If the only object in view is the proper instruction of the public, it is not necessary that the names of the medical writers or informants should be given. The newspapers can give the necessary assurance to their readers as to the professional standing of the authority quoted without mentioning names. If the journal were dissatisfied with this course it would probably be due to a desire to satisfy the curiosity of his readers about personalities rather than to a desire to instruct them on important matters. But even from the journalist's point of view adherence to the practice suggested would give him better results, since it would place at his disposal the opinions of men of greater standing and experience than are available now when names are allowed to be bandied about in public. There may be rare exceptions to this rule of anonymity as when a doctor is himself a principal actor in the circumstances under review. His intervention may be necessary, and would be meaningless if anonymous. In this case the publicity given has already been necessary on public grounds.

Speaking generally, it may be said that the medical men most often quoted in the press are not those whose opinions carry most weight with the medical profession or with the educated public. It is natural that those whom the press representatives most eagerly seek to draw into their service and utilise for their own advantage are those who have some recognised position or well-sounding address or title. It is, therefore, especially important that a stand should be made by such practitioners, who perhaps do not realise that the example set by them may well be pleaded in justification by those in a less prominent position.

Attitude of the Association.

After making all allowances for all those modes of publicity for which there may be some justification, there remain many instances which can only be regarded as gravely and unnecessarily contravening the spirit of the notice of the G.M.C. The Association is convinced that in taking up an attitude of determined opposition to these undesirable journalistic methods the Association is acting in the best interests of the public as well as of the medical profession. The extension of the system can only lead to a competition for public notice in which the abler and more scrupulous men would be left behind by those who professionally are greatly inferior, to the detriment of the public, who are ill-qualified to judge of the true worth of scientific opinions. The extension of the advertising habit among the profession in general would certainly destroy those traditions of dignity and self-respect which have helped to give the British medical profession its present high status, and would gravely undermine the amenities and harmonious working of medical practice.

The Honour of the Profession.

The Association, therefore, draws the attention of the profession to the danger of these objectionable methods, and insists upon the urgent need that every member of the profession who values its honour should offer a firm resistance to these insidious developments. If only those whose reputation is mainly derived from the newspapers allow their names and opinions to be quoted or to appear as those of "the eminent" physician, surgeon, or specialist, the practice will die a natural death.

what the medical profession conceived to be the right path. Dr. Wallace Henry proposed "The Guests," to which Prof. van den Bergh (Utrecht) responded. Mr. Hall, in conclusion, spoke with gratitude of the many groups whose help had contributed to the success of the gathering in Bradford.

THE PATHOLOGICAL MUSEUM.

A series of interesting exhibits were set out in the biological laboratory of the Technical College under the direction of a committee of which Dr. M. A. C. Bucknell was hon. secretary. Mr. Basil Hall showed specimens illustrating the surgery of the colon; Prof. F. W. Eurich a very complete exhibit illustrating anthrax and the work of the Government wool-disinfecting station at Liverpool under the charge of Mr. G. E. Duckering. Among the pathological specimens were the recent additions to the pathological museum at Leeds on which Prof. M. J. Stewart gave a demonstration.

THE EXHIBITION.

An exhibition of surgical instruments, appliances, drugs, food, &c., was held in the Windsor Halls from July 22nd to 25th. It was opened by Mr. Basil Hall in the presence of a large company, when he observed that he had opened many things in his time, some with corkscrews and some with other instruments, but he was for the first time opening an exhibition of that kind. He had no doubt of its great educational value in the suggestion of new ideas and in the inspiration of better technique. His remarks were endorsed by the Lord Mayor. A description of the exhibits will appear later.

EXCURSIONS AND SOCIAL AMENITIES.

During the stay of the Association in Bradford there were no fewer than 18 excursions, including a whole-day trip to the Lake District, the duties of transport officer being undertaken by Dr. Benjamin Wade, who secured the loan of 100 or more private cars. The staff work was so good that in no case was a party more than ten minutes late in starting. Visits were paid to Harrogate, York, and Scarborough, to the corporation water-works, and to many surrounding places of historic interest. An opportunity was afforded to those who wished it to see the various processes of local manufacture on a large scale. The official and private receptions were all largely attended. The Bradford Rotary Club gave a luncheon which led to useful interchange of opinion on some of the social problems of the moment.

At the official service at the Cathedral on Tuesday afternoon, July 22nd, the Archbishop of York spoke of the ministry of healing, and suggested that the time had come for full and impartial inquiry into the relation of body, mind, and spirit in the cure of disease. The B.M.A. Council, meeting the next day, decided that the difficulties with which this matter is at present surrounded would be likely to lead the investigation outside the sphere of the recognised activities of the Association, and after deliberation decided not to proceed with the reappointment of the committee on spiritual healing.

WELFARE OF THE BLIND.—A deputation from the National Union of the Professional and Industrial Blind was received by the Minister of Health on July 28th. The deputation, through Mr. Ben Purse, the general secretary, advanced reasons for objecting to the provisions contained in the Blind Persons Act Amending Bill now before Parliament. Mr. Purse pleaded for the further development of the present system of coöperation between the State, the local authorities, and the voluntary organisations. Mr. Wheatley was more particularly asked to take all possible steps for the prevention of blindness both in infancy and in adult life, and a number of administrative improvements were urged upon his attention. In reply, Mr. Wheatley said he was to see other deputations with regard to the blind in the course of the week, but he felt no difficulty in promising the most sympathetic consideration of all the points raised.

INDIRECT METHODS OF ADVERTISING.

REPORT OF CENTRAL ETHICAL COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

THE subject of "oblique advertising," discussed at the representative meeting of the British Medical Association on Tuesday, July 22nd, came up on a very carefully prepared report of the Central Ethical Committee. During the past few years there have been brought to the attention of this Committee certain journalistic developments which seem likely, if unchecked, seriously to undermine some of the most cherished traditions associated with medical practice in this country, and to lower the reputation of the profession among the more thoughtful sections of the community. In May, 1905, in consequence of representations made by the Association, the General Medical Council issued the following notice:—

The G.M.C. and Open Advertisements.

The practice of (*a*) advertising by a registered medical practitioner with a view to his own gain, particularly if depreciatory of other practitioners, or of sanctioning such advertising, of (*b*) employing or sanctioning the employment of agents or canvassers for the purpose of procuring patients, and of (*c*) associating with or accepting employment under any Association which practises canvassing or advertising for the purpose of procuring patients, are in the opinion of the Council contrary to the public interest and discreditable to the profession of medicine, and any registered medical practitioner resorting to any of such practices renders himself liable on proof of the facts to have his name erased from the Medical Register.

The result has undoubtedly been a great decrease in the cruder and more open forms of advertisement. The issue of handbills announcing the qualifications of medical practitioners and the door-to-door canvass for members of medical clubs are now only occasional occurrences. Of recent years, however, a subtle and indirect method of giving publicity to certain medical practitioners has obtained currency in the text and illustrations of the lay press, sometimes without and sometimes apparently with the active concurrence of those referred to. This publicity, by reason of the form that it takes and the medium that it adopts, results in a very effective advertisement for the person concerned. Such means of personal advancement may be considered legitimate in other walks of life but have in the past been shunned as undignified by the medical profession.

Scope of Warning Extended.

In February, 1922, the Association again addressed a communication to the G.M.C. asking if the time had not arrived when some authoritative pronouncement on the subject should be made. The G.M.C. replied (i.) that if a new offence not within the present Warning Notices was becoming prevalent, a flagrant case might be selected to be brought before the Council which would give it careful attention: and (ii.) that it was not the custom of the Council to issue a Warning Notice until the hearing of a case had established the need for it. At the December, 1922, Session of the G.M.C., however, one of the direct representatives of the profession on the General Medical Council raised the question afresh. As a result, it was remitted to the Executive Committee of the Council in consultation with the legal advisers, to consider and report upon the expediency of amending the Council's Warning Notice with respect to canvassing and advertising so as to make its scope more clear and comprehensive. At the June, 1923, Session of the G.M.C., the following new paragraph 6 of the Warning Notice was adopted:

Advertising and Canvassing.

The practices by a registered medical practitioner:—

(*a*) Of advertising, whether directly or indirectly, for the purpose of obtaining patients or promoting his own professional advantage; or, for any such purpose, or procuring or sanctioning or acquiescing in the publication of notices commending or directing attention to the practitioner's professional skill, knowledge, services, or qualifications, or depreciating those of others; or of being associated with or employed by those who procure or sanction such advertising or publication, and

(*b*) Of canvassing or employing any agent or canvasser for the purpose of obtaining patients; or of sanctioning or of being associated with or employed by those who sanction, such employment;

are in the opinion of the Council contrary to the public interest and discreditable to the profession of medicine, and any registered medical practitioner who resorts to any such practice renders himself liable on proof of the facts to have his name erased from the Medical Register.

The Newer Methods of Advertising.

Examples of the newer methods are to be found in interviews granted to newspaper representatives, and in signed letters or articles sent to newspapers. In many of these, members of the profession, either by the direct assertion of the journalists concerned, or by more indirect methods, are referred to as possessing, or allow it to be inferred from their own words that they possess, methods of treatment superior to those practised by others. In the opinion of the Committee the word "advertising" in connexion with the medical profession must be taken in its broadest sense, to include all those ways by which a person is made publicly known, either by himself, or by others without his objection, in a manner which can fairly be regarded as "for the purpose of obtaining patients or promoting his own professional advantage."

Accepted Customs.

It is generally accepted by the profession that certain customs are so universally practised that it cannot be said that they are for the person's own advantage, as, for instance, a door-plate with the simple announcement of the doctor's name and profession. Even this, however, may be abused by undue particularity or elaboration.

Intra-Professional Channels.—It is commonly agreed that channels must be open for discussion between members of the profession for recording the results of research and clinical experience and for bringing to the notice of other members books published and facilities for treatment offered. The recognised channels are medical societies, medical periodicals, and works primarily intended for the medical profession. The information so given is intended for the convenience and advantage of the profession, which will be in a position to judge of the value of the information and of the manner in which it is conveyed. Even this legitimate kind of advertisement is capable of abuse.

The Medical Man as Citizen.—It is the recognised duty and right of a medical man to take his share as a citizen in public life, but there is no reason why this should involve any advertisement of himself as a doctor, and, with due care, improper advertisement can be avoided.

Publicity as an Official Duty.—Publicity is rightly allowed to medical men not in actual practice of their profession since they cannot be regarded as using this publicity for the purpose of promoting their own professional advantage, and in view of the official position of medical officers of health and other medical men who hold posts in either the public health or other public service, publicity is sometimes not only permissible but necessary for the fulfilment of their official duty. The presumption in all these cases is that publicity is not sought for the individual's own gain though it is possible that the practice might be abused and the presumption therefore fail.

Books and Lectures.—The publication of books and the delivery of lectures on semi-medical topics which are of general public interest and require medical knowledge for their proper presentation have been recognised as legitimate, subject to the avoidance of methods which tend to the personal professional advantage of their authors. There are many things innocent in themselves which may, by the manner and frequency of their doing, gravely contravene the principle that medical practitioners should not advertise.

Letters to the Press: Signed or Unsigned.

From time to time there are discussed in the papers matters of great public interest or importance regarding which it is to the advantage of the public that the medical considerations involved should be stated either by letter, article, or interview. If the only object in view is the proper instruction of the public, it is not necessary that the names of the medical writers or informants should be given. The newspapers can give the necessary assurance to their readers as to the professional standing of the authority quoted without mentioning names. If the journal were dissatisfied with this course it would probably be due to a desire to satisfy the curiosity of his readers about personalities rather than to a desire to instruct them on important matters. But even from the journalist's point of view adherence to the practice suggested would give him better results, since it would place at his disposal the opinions of men of greater standing and experience than are available now when names are allowed to be bandied about in public. There may be rare exceptions to this rule of anonymity as when a doctor is himself a principal actor in the circumstances under review. His intervention may be necessary, and would be meaningless if anonymous. In this case the publicity given has already been necessary on public grounds.

Speaking generally, it may be said that the medical men most often quoted in the press are not those whose opinions carry most weight with the medical profession or with the educated public. It is natural that those whom the press representatives most eagerly seek to draw into their service and utilise for their own advantage are those who have some recognised position or well-sounding address or title. It is, therefore, especially important that a stand should be made by such practitioners, who perhaps do not realise that the example set by them may well be pleaded in justification by those in a less prominent position.

Attitude of the Association.

After making all allowances for all those modes of publicity for which there may be some justification, there remain many instances which can only be regarded as gravely and unnecessarily contravening the spirit of the notice of the G.M.C. The Association is convinced that in taking up an attitude of determined opposition to these undesirable journalistic methods the Association is acting in the best interests of the public as well as of the medical profession. The extension of the system can only lead to a competition for public notice in which the abler and more scrupulous men would be left behind by those who professionally are greatly inferior, to the detriment of the public, who are ill-qualified to judge of the true worth of scientific opinions. The extension of the advertising habit among the profession in general would certainly destroy those traditions of dignity and self-respect which have helped to give the British medical profession its present high status, and would gravely undermine the amenities and harmonious working of medical practice.

The Honour of the Profession.

The Association, therefore, draws the attention of the profession to the danger of these objectionable methods, and insists upon the urgent need that every member of the profession who values its honour should offer a firm resistance to these insidious developments. If only those whose reputation is mainly derived from the newspapers allow their names and opinions to be quoted or to appear as those of "the eminent" physician, surgeon, or specialist, the practice will die a natural death.

ANTHELMINTICS AND THEIR NOMENCLATURE.

To the Editor of The Lancet.

Sir,—In connexion with the leading article on anthelmintics in your issue of July 19th, I should like to point out that current nomenclature is in certain respects misleading and likely to cause confusion between santonin and chenopodium. Santonin is derived from santonica, the dried flower-heads of the composite *Artemisia maritima var. stachmanniana.* Artemisia assumes a great diversity of forms which were the object of attentive study on the part of the Russian botanist, Besser, in 1834–35, and his researches have resulted in the union of many supposed species under the name *Artemisia maritima.* A specimen of the plant labelled in his handwriting, with a memorandum that it was collected for medicinal use, is in the herbarium at Kew. It completely agrees with the Russian wormseed or *Flores cinæ* of commerce, cinæ being the name given to wormseed in homœopathic literature. It was first given by Wilkomm in 1872, when he described as mother plant of wormseed the Artemisia which he found in Turkestan. This Russian santonica is often known as Levant wormseed or merely as wormseed (Wurmsamen in the German Pharmacopœia), although it is not strictly a seed at all. For therapeutic use the pure definite chemical compound, santonin, is preferable to "wormseed" or santonica, as samples of wormseed are often met with which contain practically no santonin at all. Indeed, it is generally only the plant grown in Russian Turkestan which contains satisfactory amounts of santonin; attempts to grow a santonin-yielding plant in other localities have so far been unsuccessful. In veterinary practice wormseed is often preferred, and in that case care should be taken that only a genuine Russian wormseed of good quality is used.

The so-called American wormseed from which oil of chenopodium is derived is obtained from a totally different plant, belonging to a different family—namely, *Chenopodium ambrosioides anthelminticum*, and has thus nothing in common with the santonin-yielding "wormseed." The oil derived from the fruit of this plant owes its anthelmintic properties, as stated in your article, to entirely different substances from santonin, "ascaridole" being the chief. The synonym "wormseed oil" sometimes used for it is therefore unfortunate, and it should always be referred to as chenopodium oil. This confusion is particularly noticeable in German publications. In a recent paper in the *Deutsche Medizinische Wochenschrift*, describing five cases of poisoning from the oil (four of them fatal), it is indiscriminately referred to as Wurmsamenöl and Ol. Chenopodii.

I am, Sir, yours faithfully,

Percy May, D.Sc. Lond., F.I.C.

THE FACULTY OF MEDICINE IN THE UNIVERSITY OF LONDON.

To the Editor of The Lancet.

Sir,—The letter in your issue of July 19th, signed by Profs. Parsons, Frazer, and Barclay-Smith, is a valuable and much needed protest against decisions on important medical questions being taken by the Senate of the University of London, without consultation of the Boards of Studies in Medicine or of the Faculty itself. The signatories to the letter prefer (I think rightly) that the whole Faculty should be consulted in such cases.

A curiously pertinent instance of a tendency to ignore the existence of the Faculty occurred at the last meeting of the Senate (on July 23rd). In my capacity as chairman of the Council for External Students I brought forward a resolution, passed unanimously by my Council, recommending that a proposition to institute a new degree in the Faculty of Medicine should be referred to that Faculty before the Senate in fact instituted the new degree. This resolution was opposed at the Senate by the Dean of the Faculty of Medicine, who enunciated the astonishing doctrine that it was useless to consult that Faculty because its membership was too large. Disfranchisement seems an odd reward for vigorous expansion! Chiefly as a result of this unexpected opposition by the titular head of the Faculty my motion was defeated, and a new degree, Bachelor of Pharmacy, in the Faculty of Medicine will accordingly be established without the wishes of the Faculty or any of its Boards of Studies being ascertained. I think it behoves the Faculty to assert its rights and to insist upon its views being heard in matters of grave medical importance, notwithstanding the strange reluctance of its Dean to consult the body to which he owes his seat upon the Senate.

I am, Sir, yours faithfully,

E. Graham Little,
Representative on the Senate of the Medical and Surgical Graduates of Convocation.

July 26th, 1924.

THE USE OF CEREALS IN PRESERVATION OF THE TEETH.

To the Editor of The Lancet.

Sir,—In your issue of July 19th you draw attention in an editorial article to certain experiments on the cereal feeding of dogs: similar experiments are recorded in the second edition of the Report on the Present State of Knowledge of Accessory Food Factors (Vitamins) published by the Medical Research Council (Special Report Series, No. 38, revised).

The Bread and Food Reform League has for many years directed attention to the value of whole cereals as a means of securing good teeth, and is therefore concerned lest any misinterpretation of the results of these experiments should bring this valuable prophylactic into disrepute. In the report quoted above it is stated (p. 96) that it was found by E. Mellanby, while investigating the experimental production of rickets in puppies, "that of the cereals examined, oatmeal, as bought in the shops, was the most potently rickets-producing, and that the disease developed much more seriously and rapidly on oatmeal than on whole wheaten meal, white wheaten flour, or rice. The difference between the action of wholemeal and white flour and rice was not so great, but wholemeal flour was slightly worse than white flour and rice." Again (p. 150): "Cereals differed in their detrimental action on teeth-formation—oatmeal was the worst of those examined; white flour and rice the best." It is further stated (p. 96) that "The explanation of these unexpected results obtained with different cereals has not yet been suggested."

Now the following facts about whole cereals, to which the Bread and Food Reform League has for many years directed attention, may help to solve this problem. It is agreed that, in order to form good bones and teeth, it is necessary not only that food should contain phosphorus, lime, and the growth-promoting and antirachitic vitamins, but also that the adequacy of calcification is influenced by the amount and *balance* of these substances in the diet. As far back as 1880 it was recognised that whole cereals contained a large proportion of phosphorus and a limited amount of lime. Therefore, as the late Sir Arthur Church, F.R.S., stated, wholemeal bread should be supplemented as a diet by a plentiful supply of green vegetables. The amount of calcium in 5 per cent. of whole-milk does not, according to McCollum, furnish enough calcium to balance diets consisting of cereals, legume seeds, tubers, fleshy roots, and meat (Johns Hopkins Hospital Bulletin, 1922).

I suggest, therefore, that puppies fed on oatmeal and milk did not obtain sufficient calcium to balance the large amount of phosphorus found in oats, and that it is for this reason that they had defective teeth. Mellanby's experiments showed that the addition of cod-liver oil to the diet of these puppies "completely transformed the structure of the teeth." However, the wide variations in metabolism as evidenced by the difference in susceptibility of different animals to the diseases produced by diet, "suggest caution in applying results indiscriminately from one animal to another" (report quoted above, p. 84). In guinea-pigs, for example, deficiency of the *antiscorbutic* vitamin resulted in defective teeth (Zilva and Wells), while McCollum and his co-workers (1922) incriminated the absence of this vitamin as a factor in producing oral disease.

It is not contended by anyone that wholemeal bread taken alone forms perfectly balanced food, but that in conjunction with green vegetables and fats containing vitamins C and A it forms a better balanced dietary than does white bread. It would be most unfortunate if, as the result of a few experiments on puppies, the impression should be spread that cereals have a detrimental effect on tooth and bone formation, especially since whole nations, for example, the inhabitants of the Northern Provinces of India, who live principally on wheatmeal, are known to have excellent teeth.

I am, Sir, yours faithfully,

MAY YATES,

Hon. Sec. Bread and Food Reform League.

TRAINING OF NURSES.

To the Editor of THE LANCET.

SIR,—It will be remembered that at the recent British Hospitals Association meetings in London I raised the question as to the regulations of the General Nursing Council with regard to the recognition of smaller hospitals in the training of nurses. Since then I have been in correspondence with Sir Wilmot Herringham and the General Nursing Council, and to-day I have received a letter of which a copy is appended.

The General Nursing Council,
12, York Gate, Regent's Park,
London, N.W. 1.
28th July, 1924.

DEAR SIR,—The Council on July 25th resolved that the following be added to the scheme for the training of nurses who will be admitted to the Register after the training and examination rules come into operation:—

"I. (3) There are other hospitals which are sufficiently large, but from deficiency of clinical material in some branch cannot be approved as complete training schools. Such hospitals will be required to associate themselves with another hospital or hospitals in order to supply for their nurses that part of the training in which they are deficient. The Council is prepared to consider any scheme for carrying out such an arrangement, but the period of training must extend over three years and six months and it will be for the hospitals who propose to associate themselves to satisfy the Council that the arrangements will be adequate to afford a complete training. Such hospitals will be entitled 'Associated Hospitals.'"

Your hospital will fall under this rule. We have no reason to anticipate that the Minister of Health will disapprove the rule.

Yours faithfully,

MARIAN C. RUNDLE,

Registrar.

As this question is of immediate and the utmost importance to the smaller hospitals of our country, I shall be glad if you will insert this letter in your next issue. I also desire to take this opportunity personally to thank the representatives of nearly 30 hospitals who were good enough to express their kind appreciation of my efforts.

I am, Sir, yours faithfully,

Grimsby, July 29th, 1924. JOHN BARKER.

SQUINT, LEFT-HANDEDNESS AND STAMMER.

To the Editor of THE LANCET.

SIR,—My son, when about 5 years old, showed himself left-handed at games, and as this peculiarity has been a difficulty of mine, I determined to save him in his turn from the defect. With this in view I spent some hours bowling to him on the condition that he should use his bat right-handed. I was successful, he was cured of the habit. A few years after this he developed a marked hesitation of speech, and I have been informed that this affection is a not infrequent result of the correction of a left-handed habit. For want of a term I coined one. I had produced "inverted cerebration." The college authorities of a large school here advised me to put him under Mr. Schnelle, of Bedford Mansions, and I am grateful to him for the result. The boy is almost entirely cured. Mr. Schnelle in answer to my questions says he has known similar cases. What I should like to ask in your columns is this: What is the position as regards other functions? Does the "inverted cerebration" confine its pernicious effects to the speech centre? I should be grateful for any help on the point. I am, Sir, yours faithfully,

July 28th, 1924. F.R.C.S. Irel.

⁂ Dr. W. S. Inman sends us this week an interesting article in which this subject is dealt with.—ED. L.

Parliamentary Intelligence.

HOUSE OF LORDS.

Workmen's Compensation (Silicosis) Bill.

ON Thursday, July 24th, the Workmen's Compensation (Silicosis) Bill was read a second time. On Tuesday, July 29th, the Bill was read a third time and passed.

HOUSE OF COMMONS.

TUESDAY, JULY 22ND.

Educational Health Services.

The House went into Committee of Supply on a vote of £25,900,000 for the salaries and expenses of the Board of Education, Mr. ROBERT YOUNG, Chairman of Committees, in the chair.

Mr. TREVELYAN (President of the Board of Education) said many schools which were in process of condemnation before the war were still in existence and had remained untouched and unimproved. Many of those schools were ill-lighted, overcrowded, and even insanitary, and many of them had barely any playground and some none at all. He was at this moment having a complete survey made by his inspectors, and in the course of the autumn he would make clear what school buildings could be allowed only a limited period for their continued existence. Some of them would have to be condemned outright and the reconstruction of others would be required. He did not intend to set up too high a standard for the poor sorts of school, for if he wanted satisfactory school buildings everywhere he would have to condemn schools in droves in every county. What he was going to do was to get rid of the worst schools.

Replying to subsequent discussion, Mr. MORGAN JONES (Parliamentry Secretary of the Board of Education) said no reasonable proposal for the erection of new school clinics or for the extension of the buildings where treatment was provided had been rejected by the Board. The number of new special schools certified since April 1st, 1923, was 13, and since Jan. 1st four of these 13 had been approved.

The vote was agreed to.

ANTHELMINTICS AND THEIR NOMENCLATURE.

To the Editor of THE LANCET.

SIR,—In connexion with the leading article on anthelmintics in your issue of July 19th, I should like to point out that current nomenclature is in certain respects misleading and likely to cause confusion between santonin and chenopodium. Santonin is derived from santonica, the dried flower-heads of the composite *Artemisia maritima var. stachmanniana.* Artemisia assumes a great diversity of forms which were the object of attentive study on the part of the Russian botanist, Besser, in 1834–35, and his researches have resulted in the union of many supposed species under the name *Artemisia maritima.* A specimen of the plant labelled in his handwriting, with a memorandum that it was collected for medicinal use, is in the herbarium at Kew. It completely agrees with the Russian wormseed or *Flores cinæ* of commerce, cinæ being the name given to wormseed in homœopathic literature. It was first given by Wilkomm in 1872, when he described as mother plant of wormseed the Artemisia which he found in Turkestan. This Russian santonica is often known as Levant wormseed or merely as wormseed (Wurmsamen in the German Pharmacopœia), although it is not strictly a seed at all. For therapeutic use the pure definite chemical compound, santonin, is preferable to "wormseed" or santonica, as samples of wormseed are often met with which contain practically no santonin at all. Indeed, it is generally only the plant grown in Russian Turkestan which contains satisfactory amounts of santonin; attempts to grow a santonin-yielding plant in other localities have so far been unsuccessful. In veterinary practice wormseed is often preferred, and in that case care should be taken that only a genuine Russian wormseed of good quality is used.

The so-called American wormseed from which oil of chenopodium is derived is obtained from a totally different plant, belonging to a different family—namely, *Chenopodium ambrosioides anthelminticum,* and has thus nothing in common with the santonin-yielding "wormseed." The oil derived from the fruit of this plant owes its anthelmintic properties, as stated in your article, to entirely different substances from santonin, "ascaridole" being the chief. The synonym "wormseed oil" sometimes used for it is therefore unfortunate, and it should always be referred to as chenopodium oil. This confusion is particularly noticeable in German publications. In a recent paper in the *Deutsche Medizinische Wochenschrift,* describing five cases of poisoning from the oil (four of them fatal), it is indiscriminately referred to as Wurmsamenöl and Ol. Chenopodii.

I am, Sir, yours faithfully,

PERCY MAY, D.Sc. Lond., F.I.C.

THE FACULTY OF MEDICINE IN THE UNIVERSITY OF LONDON.

To the Editor of THE LANCET.

SIR,—The letter in your issue of July 19th, signed by Profs. Parsons, Frazer, and Barclay-Smith, is a valuable and much needed protest against decisions on important medical questions being taken by the Senate of the University of London, without consultation of the Boards of Studies in Medicine or of the Faculty itself. The signatories to the letter prefer (I think rightly) that the whole Faculty should be consulted in such cases.

A curiously pertinent instance of a tendency to ignore the existence of the Faculty occurred at the last meeting of the Senate (on July 23rd). In my capacity as chairman of the Council for External Students I brought forward a resolution, passed unanimously by my Council, recommending that a proposition to institute a new degree in the Faculty of Medicine should be referred to that Faculty before the Senate in fact instituted the new degree. This resolution was opposed at the Senate by the Dean of the Faculty of Medicine, who enunciated the astonishing doctrine that it was useless to consult that Faculty because its membership was too large. Disfranchisement seems an odd reward for vigorous expansion! Chiefly as a result of this unexpected opposition by the titular head of the Faculty my motion was defeated, and a new degree, Bachelor of Pharmacy, in the Faculty of Medicine will accordingly be established without the wishes of the Faculty or any of its Boards of Studies being ascertained. I think it behoves the Faculty to assert its rights and to insist upon its views being heard in matters of grave medical importance, notwithstanding the strange reluctance of its Dean to consult the body to which he owes his seat upon the Senate.

I am, Sir, yours faithfully,

E. GRAHAM LITTLE,

Representative on the Senate of the Medical and Surgical Graduates of Convocation.

July 26th, 1924.

THE USE OF CEREALS IN PRESERVATION OF THE TEETH.

To the Editor of THE LANCET.

SIR,—In your issue of July 19th you draw attention in an editorial article to certain experiments on the cereal feeding of dogs: similar experiments are recorded in the second edition of the Report on the Present State of Knowledge of Accessory Food Factors (Vitamins) published by the Medical Research Council (Special Report Series, No. 38, revised).

The Bread and Food Reform League has for many years directed attention to the value of whole cereals as a means of securing good teeth, and is therefore concerned lest any misinterpretation of the results of these experiments should bring this valuable prophylactic into disrepute. In the report quoted above it is stated (p. 96) that it was found by E. Mellanby, while investigating the experimental production of rickets in puppies, "that of the cereals examined, oatmeal, as bought in the shops, was the most potently rickets-producing, and that the disease developed much more seriously and rapidly on oatmeal than on whole wheaten meal, white wheaten flour, or rice. The difference between the action of wholemeal and white flour and rice was not so great, but wholemeal flour was slightly worse than white flour and rice." Again (p. 150): "Cereals differed in their detrimental action on teeth-formation—oatmeal was the worst of those examined; white flour and rice the best." It is further stated (p. 96) that "The explanation of these unexpected results obtained with different cereals has not yet been suggested."

Now the following facts about whole cereals, to which the Bread and Food Reform League has for many years directed attention, may help to solve this problem. It is agreed that, in order to form good bones and teeth, it is necessary not only that food should contain phosphorus, lime, and the growth-promoting and antirachitic vitamins, but also that the adequacy of calcification is influenced by the amount and *balance* of these substances in the diet. As far back as 1880 it was recognised that whole cereals contained a large proportion of phosphorus and a limited amount of lime. Therefore, as the late Sir Arthur Church, F.R.S., stated, wholemeal bread should be supplemented as a diet by a plentiful supply of green vegetables. The amount of calcium in 5 per cent. of whole-milk does not, according to McCollum, furnish enough calcium to balance diets consisting of cereals, legume seeds, tubers, fleshy roots, and meat (Johns Hopkins Hospital Bulletin, 1922).

I suggest, therefore, that puppies fed on oatmeal and milk did not obtain sufficient calcium to balance the large amount of phosphorus found in oats, and that it is for this reason that they had defective teeth. Mellanby's experiments showed that the addition of cod-liver oil to the diet of these puppies "completely transformed the structure of the teeth." However, the wide variations in metabolism as evidenced by the difference in susceptibility of different animals to the diseases produced by diet, "suggest caution in applying results indiscriminately from one animal to another" (report quoted above, p. 84). In guinea-pigs, for example, deficiency of the *antiscorbutic* vitamin resulted in defective teeth (Zilva and Wells), while McCollum and his co-workers (1922) incriminated the absence of this vitamin as a factor in producing oral disease.

It is not contended by anyone that wholemeal bread taken alone forms perfectly balanced food, but that in conjunction with green vegetables and fats containing vitamins C and A it forms a better balanced dietary than does white bread. It would be most unfortunate if, as the result of a few experiments on puppies, the impression should be spread that cereals have a detrimental effect on tooth and bone formation, especially since whole nations, for example, the inhabitants of the Northern Provinces of India, who live principally on wheatmeal, are known to have excellent teeth.

I am, Sir, yours faithfully,

MAY YATES,

Hon. Sec. Bread and Food Reform League.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to each member of the medical profession. If the form has not been received, a duplicate will be sent on request. We shall be grateful for the return of the forms by an early post.

We are, Sir, yours faithfully,

J. & A. CHURCHILL.

7, Great Marlborough-street, London, W.1,
July 29th, 1924.

TRAINING OF NURSES.

To the Editor of THE LANCET.

SIR,—It will be remembered that at the recent British Hospitals Association meetings in London I raised the question as to the regulations of the General Nursing Council with regard to the recognition of smaller hospitals in the training of nurses. Since then I have been in correspondence with Sir Wilmot Herringham and the General Nursing Council, and to-day I have received a letter of which a copy is appended.

The General Nursing Council,
12, York Gate, Regent's Park,
London, N.W. 1.
28th July, 1924.

DEAR SIR,—The Council on July 25th resolved that the following be added to the scheme for the training of nurses who will be admitted to the Register after the training and examination rules come into operation:—

"I. (3) There are other hospitals which are sufficiently large, but from deficiency of clinical material in some branch cannot be approved as complete training schools. Such hospitals will be required to associate themselves with another hospital or hospitals in order to supply for their nurses that part of the training in which they are deficient. The Council is prepared to consider any scheme for carrying out such an arrangement, but the period of training must extend over three years and six months and it will be for the hospitals who propose to associate themselves to satisfy the Council that the arrangements will be adequate to afford a complete training. Such hospitals will be entitled 'Associated Hospitals.'"

Your hospital will fall under this rule. We have no reason to anticipate that the Minister of Health will disapprove the rule.

Yours faithfully,

MARIAN C. RUNDLE,

Registrar.

As this question is of immediate and the utmost importance to the smaller hospitals of our country, I shall be glad if you will insert this letter in your next issue. I also desire to take this opportunity personally to thank the representatives of nearly 30 hospitals who were good enough to express their kind appreciation of my efforts.

I am, Sir, yours faithfully,

Grimsby, July 29th, 1924. JOHN BARKER.

SQUINT, LEFT-HANDEDNESS AND STAMMER.

To the Editor of THE LANCET.

SIR,—My son, when about 5 years old, showed himself left-handed at games, and as this peculiarity has been a difficulty of mine, I determined to save him in his turn from the defect. With this in view I spent some hours bowling to him on the condition that he should use his bat right-handed. I was successful, he was cured of the habit. A few years after this he developed a marked hesitation of speech, and I have been informed that this affection is a not infrequent result of the correction of a left-handed habit. For want of a term I coined one. I had produced "inverted cerebration." The college authorities of a large school here advised me to put him under Mr. Schnelle, of Bedford Mansions, and I am grateful to him for the result. The boy is almost entirely cured. Mr. Schnelle in answer to my questions says he has known similar cases. What I should like to ask in your columns is this: What is the position as regards other functions? Does the "inverted cerebration" confine its pernicious effects to the speech centre? I should be grateful for any help on the point.

I am, Sir, yours faithfully,

July 28th, 1924. F.R.C.S. Irel.

*** Dr. W. S. Inman sends us this week an interesting article in which this subject is dealt with.—ED. L.

Parliamentary Intelligence.

HOUSE OF LORDS.

Workmen's Compensation (Silicosis) Bill.

ON Thursday, July 24th, the Workmen's Compensation (Silicosis) Bill was read a second time. On Tuesday, July 29th, the Bill was read a third time and passed.

HOUSE OF COMMONS.

TUESDAY, JULY 22ND.

Educational Health Services.

The House went into Committee of Supply on a vote of £25,900,000 for the salaries and expenses of the Board of Education, Mr. ROBERT YOUNG, Chairman of Committees, in the chair.

Mr. TREVELYAN (President of the Board of Education) said many schools which were in process of condemnation before the war were still in existence and had remained untouched and unimproved. Many of those schools were ill-lighted, overcrowded, and even insanitary, and many of them had barely any playground and some none at all. He was at this moment having a complete survey made by his inspectors, and in the course of the autumn he would make clear what school buildings could be allowed only a limited period for their continued existence. Some of them would have to be condemned outright and the reconstruction of others would be required. He did not intend to set up too high a standard for the poor sorts of school, for if he wanted satisfactory school buildings everywhere he would have to condemn schools in droves in every county. What he was going to do was to get rid of the worst schools.

Replying to subsequent discussion, Mr. MORGAN JONES (Parliamentry Secretary of the Board of Education) said no reasonable proposal for the erection of new school clinics or for the extension of the buildings where treatment was provided had been rejected by the Board. The number of new special schools certified since April 1st, 1923, was 13, and since Jan. 1st four of these 13 had been approved.

The vote was agreed to.

Public-Health (Scotland) Amendment Bill.

On the motion for the third reading of the Public Health (Scotland) Amendment Bill,

Mr. Buchanan said he regretted that the Bill had been amended in Committee and that the Secretary for Scotland was going to be prevented in the future if science found some new method of dealing with disease from being able to carry that remedy to the poor people at the earliest possible moment. If the question of expense was going to be raised at all it should not be raised on a Bill of this sort. While accepting this Bill he expressed the hope that the Secretary for Scotland would in a short time go into the whole question of coördinating the health services and would help the local authorities in more generous fashion.

Sir J. Gilmour said it was only right that Parliament should know of any fresh departure which was made in these grave medical matters and that they should also know through the Minister concerned why orders were proposed. Parliament should know to what the local authorities were being committed. If any fresh discovery was made in regard to the cure of such a fell disease as cancer the House of Commons, however it might be composed, would give its consent to any measure provided that it was satisfied that it was a correct one and was approved by the medical profession.

The Bill was read a third time.

Wednesday, July 23rd.

Deaths in Urban and Rural Areas.

Mr. Black asked the Minister of Health whether he could account for the large variations given in the figures supplied by him on July 1st in the deaths in urban areas—viz., fluctuations from 7·2 to 16·5 per 1000, and in rural areas fluctuations from 7·0 to 19·7 per 1000; whether the higher rates applied to areas where sanitary conditions were the worst and the public medical and maternity services were least efficient; and whether he proposed any measures to bring down the high incidence of mortality in certain areas to that of the lower.—Mr. Wheatley replied: I am advised that the considerable variations in the death-rate for 1923 as between area and area cannot be assigned to specific causes, and, moreover, that it is hazardous to attempt to draw inferences from the mortality-rates for a single year. It is, however, the fact that, in the case of both the urban and the rural area with the highest rates for 1923, the sanitary conditions are not satisfactory, and my department is giving attention to these conditions.

Lymph used at Hendon Institute.

Mr. Black asked the Minister of Health whether he would investigate the records which have been kept showing the pedigree of the lymph used at the Hendon institute; what was the nature and origin of the strains of lymph now in circulation by the Government; and whether he could supply a chart showing the pedigree of a single strain of lymph now in use.—Mr. Wheatley replied: The records show that the lymph now used at the Government Lymph Establishment is derived from calf lymph originally obtained from Cologne and the strain has since been carried on, as the hon. Member was informed on April 2nd last, by repeated transference from animal to animal. I fear it is impracticable to chart the pedigree as suggested in a form which would be readily understood.

National Health Insurance.

Mr. William M. Adamson asked the Minister of Health if the National Health Insurance (Prolongation of Insurance) Act would be renewed for 1925.—Mr. Wheatley replied: Provision has been included in the expiring Laws Continuance Bill now before Parliament for the extension until Dec. 31st, 1925, of the operation of the National Health Insurance (Prolongation of Insurance) Act.

Maternal Mortality in Kensington.

Mr. James Gardner asked the Minister of Health whether he was aware that the rate per annum of maternal mortality per 1000 births was for 1919–21, Kensington 4·31, Poplar 2·90, and West Ham 2·03, and Kensington, in 1921, 3·9, in 1922, 5·0, and in 1923, 5·8; whether he was aware that this high maternal mortality in Kensington almost wholly occurred among the poorer classes; whether he would give the figures of maternal mortality in Poplar and West Ham for 1923; and whether his medical staff would investigate and inquire whether necessitous mothers and expectant mothers in Kensington received sufficient assistance in midwifery and suitable food either from the guardians or the borough council.—Mr. Wheatley replied: The rates given in the first part of the question are the maternal mortality-rates for the period 1919–22, not 1919–21. For Kensington, the rate was 4·10 in 1921, 4·76 in 1922, and 4·81 in 1923; for Poplar and West Ham, the rates in 1923 were 3·29 and 3·08 respectively. I am well aware of the high maternal mortality in Kensington, which no doubt occurs mainly among the poorer classes, and the borough council have recently taken steps to improve and extend the midwifery facilities in the borough. The council have, for some time past, made arrangements for the supply of meals and milk to expectant and nursing mothers in necessitous cases.

Geneva Committee on Anthrax.

Mr. Somerville Hastings asked the Minister of Health what conclusion had been reached by the Committee on Anthrax at the recent International Labour Conference at Geneva, in view of the substantial number of cases of anthrax which continued to occur and the admitted fact that the work of the disinfecting station at Liverpool could not be wholly efficient until supplemented by international action.—Mr. Davies (Under-Secretary to the Home Office) replied: I am not quite sure that I understand my hon. friend's meaning. The recent international conference rejected the proposal of the British Government that the question of an international convention in regard to the disinfection of infected varieties of wool should be placed on the agenda of next year's conference, notwithstanding that the proposal was based on the report of the International Anthrax Committee which recommended such disinfection. The policy of the British Government is not, however, dependent on the conclusion of an international convention on the subject. Parliament has already by the Anthrax Prevention Act, 1919, authorised the necessary measures for securing such disinfection in the case of infected material imported into this country, and it is the intention of the Government to proceed with the measures that were initiated by their predecessors for this purpose.

Houses Built under the Addison Scheme.

Mr. Mardy Jones asked the Minister of Health what was the total number of dwelling-houses built under the Addison scheme during each year from 1919 to 1923, inclusive.—Mr. Wheatley replied: The numbers of houses completed in each year from 1919 to 1923 under schemes authorised by the Housing Acts of 1919 were as follows:—

Year.	Local authorities' and public utility societies' schemes.	Private builders' subsidy schemes.	Total.
1919	100	—	100
1920	9,171	6,540	15,711
1921	68,255	18,414	86,660
1922	74,769	14,232	89,001
1923	15,679	—	15,679
Total ..	167,974	39,186	207,160

Out-relief in England.

Mr. Graham White asked the Minister of Health the number of persons in receipt of out-relief in England as on Jan. 1st and July 1st, 1924.—Mr. Wheatley replied: On the nearest dates to those named for which figures are available the numbers were 961,297 and 846,458.

Thursday, July 24th.

Ministry of Pensions Hospitals.

Mr. Darbishare asked the Minister of Pensions the number of hospitals now under the administration of the Ministry; the number of beds occupied and vacant; and the total annual expenditure incurred in maintaining these hospitals, including medical staff, &c.—Mr. F. O. Roberts replied: The present number of military hospitals is 33, the number of occupied beds 6249, and of vacant beds 1188. This latter figure is temporarily in excess of the normal number of vacant beds which must be kept for the change of patients. This is due to the fact that certain hospitals, no longer required, are being vacated but are still partially occupied pending evacuation. The expenditure by the Ministry in maintaining these hospitals is estimated at £755,000 for the present financial year.

Tuberculosis in the Scottish Highlands.

Mr. MacKenzie Livingstone asked the Secretary for Scotland in view of the present high death-rate from tuberculosis due to the deplorable housing conditions in various crofting areas in the Highlands of Scotland, when he proposed to take steps to improve the housing conditions in the Highlands.—Mr. Adamson replied: I am aware that the death-rate from tuberculosis in various crofting areas is high, though I cannot admit that bad housing is the sole contributory cause. Considerable improvements have recently taken place in the housing conditions in many districts of the Highlands and Islands. Facilities for improving the housing conditions in the Highlands and Islands are already available under the existing law and will be extended to some extent under the provisions of the Housing Bill. Under that Bill the whole area within the Highlands and Islands (exclusive of burghs) will be a rural area within which the higher rate of subsidy will be payable in cases to which it is applicable. Under existing arrangements crofters are entitled to assistance on special terms from the Board of Agriculture for the improvement and provision of houses and in addition they may obtain a subsidy from the local authority in terms of Section 2 of the Housing Act of 1923. Under Clause 7 of the present Bill if a local authority fails to take steps to make the subsidy under the Act of 1923 available to crofters the Board may pay it direct. So far as the second part of the question is concerned every step which it is possible for me to take to accelerate improvement in the housing conditions will be taken.

Single Room Tenements in England and Wales.

Mr. ALDEN asked the Minister of Health what were the last available figures as to the number of single-room tenements in England and Wales.—Mr. GREENWOOD replied: According to the 1921 census, which furnishes the most recent figures available on the subject, there were 317,417 private families in England and Wales occupying one room or less apiece, the aggregate number of rooms occupied by them being 317,260.

New Child Welfare Centres.

Mr. ALDEN asked the Minister of Health the number of new child welfare centres at December, 1923, and at the present time.—Mr. GREENWOOD replied: According to the information in the possession of my department the number of maternity and child welfare centres in England and Wales was 2201 on Dec. 1st, 1923, and 2,272 on July 1st, 1924.

MONDAY, JULY 28TH.

Composition of Patent Medicines.

Sir KINGSLEY WOOD asked the Minister of Health whether his attention had been called to the dangers arising from the unrestricted sales of certain patent medicines; that their manufacturers were not compelled to disclose the composition of the product bearing their labels or prevented from advertising it as a cure for a particular ailment; and whether he proposed to take any action in the matter to further protect the public.—Mr. GREENWOOD replied: My right hon. friend's attention has been called to this matter, but he fears that in the present state of business the Government cannot undertake to introduce legislation on this subject during the present session.

Maternity Benefits in India.

Mr. SCURR asked the Under Secretary of State for India whether it was the intention of the Government of India to ratify the proposals of the International Labour Convention of Washington concerning maternity benefits.—Mr. RICHARDS replied: The answer is in the negative. The Washington Conference of 1919 resolved that the Indian Government should be requested to make a study of the question of the employment of women before and after confinement, and of maternity benefits, and to report on these matters.

Child Mortality in Bombay.

Mr. SCURR asked the Under Secretary of State for India the mortality-rate for children under one year and under five years for each of the years 1919, 1920, 1921, 1922, and 1923 in Bombay.—Mr. RICHARDS replied: The following are the figures for 1919 and 1920:—

Ratio of Deaths per 1000 of Population in Bombay Presidency According to Age.

Year.	Under 1 year.		1 year and under 5 years.	
	Males.	Females.	Males.	Females.
1919	206·70	196·73	56·48	55·32
1920	191·42	174·26	45·60	43·20

The figures for 1921, 1922, and 1923 are not yet available.

TUESDAY, JULY 29TH.

Assaults on Young Girls.

Sir THOMAS BRAMSDON asked the Home Secretary if he was now in a position to give the names of the members of the departmental committee who will inquire into the subject of assault on young girls, the terms of reference, and any other information relating to the matter.—Mr. DAVIES (Under Secretary to the Home Office) replied: My right hon. friend has now appointed a committee under the chairmanship of Sir Ryland Adkins, K.C., with the following terms of reference: "To collect information and to take evidence as to the prevalence of sexual offences against young persons, and to report upon the subject, indicating any direction in which, in their opinion, the law or its administration might be improved." The other members are Mr. H. W. Disney, Miss E. H. Kelly, J.P., Miss Clara Martineau, J.P., Dr. A. H. Norris, Mr. R. J. Parr, Mrs. Rackham, J.P., and Sir Guy Stephenson. The secretary is Miss J. I. Wall, of the Home Office.

Medical News.

UNIVERSITY OF OXFORD.—The following degrees in medicine have been conferred at recent Congregations:—

D.M.—N. F. Smith, Balliol; H. H. Sanguinetti, Wadham; J. F. Venables, Magdalen; and G. K. Stone, Trinity.

B.M.—R. E. D. Cargill, Christ Church; W. J. E. Lupton, New; K. J. Franklin, Oriel; G. R. P. Aldred-Brown, Keble; H. W. Pearson, Brasenose; C. J. Fuller, Queen's; A. A. F. Peel, University; G. P. Wright, Exeter; C. W. Carter, and G. I. Wilson, Queen's; W. H. Bradley, Christ Church; D. R. Gawler, University; C. A. H. Green, Trinity; A. D. Dyson, Corpus Christi; and E. H. Koerner, Magdalen.

UNIVERSITY OF LONDON.—Dr. A. W. M. Ellis, who has been appointed as from Oct. 1st, 1924, to the University chair of medicine tenable at the London Hospital Medical College, was educated at Upper Canada College and at the University of Toronto. In 1908–09 he served as house physician and house surgeon in the Hospital for Sick Children, Toronto, and during 1909–10 he was resident pathologist at the Lakeside Hospital, Cleveland, Ohio, and demonstrator in pathology in the Western Reserve University Medical School. In 1910–11 he assisted in the teaching of pathological chemistry at the University of Toronto. From 1911 to 1914 he was assistant physician to the hospital of the Rockefeller Institute. During the war he was in charge of the Cerebro-spinal Fever Hospital at Bulford (1914–15), from where he proceeded to France with the 1st Canadian Division, becoming officer commanding the Canadian Mobile Laboratory in 1916. In 1918 he was appointed adviser in pathology to the Fourth Army. In 1919 he received a grant from the Medical Research Council and since 1920 he has been assistant director of the medical unit at the London Hospital.

At a recent meeting of the Senate, the Vice-Chancellor (Prof. E. A. Gardner) being in the chair, the Bethlem Royal Hospital was admitted as a school of the University in the Faculty of Medicine for the purpose of research in psychological medicine. The resignation by Prof. H. R. Kenwood, of the Chadwick Chair of Hygiene at University College, as from December next, was accepted with regret, and with an expression of appreciation of his long and valued services to the College and to the University. Sir Wilmot P. Herringham has been elected chairman of the committee of the medical members of the Senate for 1924–25.

At examinations held recently the following candidates were successful:—

M.D. EXAMINATION.

Branch I., Medicine.—John A. Birrell, Univ. Coll Cardiff and St. George's Hosp.; Florence R. Dingley, Univ. Coll. Hosp.; Arthur H. Douthwaite, Guy's Hosp.; John N. Kerr, (University Medal), St. Bart.'s Hosp.; Reginald C. Lightwood, King's Coll. Hosp.; and Gladys M. Wauchope, St. Andrews University and London Hosp.

Branch IV., Midwifery and Diseases of Women.—Janet K. Aitken and Edith K. Budden, London Sch. of Med. for Women; Calvert M. Gwillim, St. Bart.'s Hosp.; Dorothy McNair, London Sch. of Med. for Women; and Kathleen H. Matthews, London Sch. of Med. for Women and St. Mary's Hosp.

Branch V., State Medicine.—Harry Shannon, St. Bart.'s Hosp. and Univ. Coll.

M.S. EXAMINATION.

Branch I., Surgery.—Grant Massie, Guy's Hosp.; and Arthur D. Wright, St. Mary's Hosp.

Branch IV., Laryngology, Otology, and Rhinology.—Victor E. Negus (University Medal), King's Coll. Hosp.

UNIVERSITY OF WALES.—At a recent congregation held at University College of North Wales, Bangor, the following degrees were conferred:—

M.B., B.Ch.—David I. Bowen, Daniel T. Davies, Edith M. Davies, Leslie C. Edwards, Martha Griffith, Emrys D. Owen, and Constance Walters.

M.Sc. (hon. causa).—Dr. Harry Drinkwater.

LL.D. (hon. causa).—Sir Donald MacAlister.

UNIVERSITY OF EDINBURGH.—At the graduation ceremonial on July 25th the following degrees were conferred:—

DOCTOR OF MEDICINE.

Alexander G. Biggam, Arnold Davies, *George D. Fairley, *Thomas Ferguson, ‡Shankar W. Hardikar, †John F. C. Haslam, †Thomas D. Inch, †John Jeffrey, *Frans Krone, *Abdurrahman Khan Lauddie (in absentia), ‡Robert C. Low, *Harry S. Lucraft, Douglas I. O. Macaulay, Edward S. Massiah (in absentia), Charles I. Milne, Janet M. Murray, John O. Murray, Owen T. Owen, *Graham C. Ramsay (in absentia), James W. G. H. Riddel, Stephen Rowland, Arnold H. Shennan, *Basil H. H. Spence, *Adam White, *Stephen H. Wilkinson, ‡George S. Williamson, and Edward A. Wilson.

* Commended for thesis. † Highly commended for thesis.
‡ Awarded gold medal for thesis.

Bachelor of Medicine and Bachelor of Surgery.

*Alexander M. Affleck, James A. Aitchison, James Aitken, Agnes M. Allan, Arthur J. W. Allen, Arthur A. Allison, *James M. Alston, James M. Anderson, Rupert G. Anderson, William L. Anderson, Frank R. Ashton, Douglas Bell, Richard Bell, Roland A. Bennett, William D. Bertram, Charles M. Bethune, William J. Bethune, Wilhelmus H. Biccard, Charles A. Bingham, Robert A. F. Blair, *Thomson Bonar, Marion Bow, Tom R. Bowden, Eric P. Boyle, Cuthbert A. Bozman, Abraham Brodie, Marjorie I. Brotherston, Kenneth R. Brown, Margaret C. Bruce, Joyce L. Bunting, Cyril P. Burges, Margaret C. Burnett White, Robertha Burt, Rennie C. Burton, Fernie L. Buttar, Bertha M. Butters, Donald Cameron, Ian M'D. Cameron, Angus F. Campbell, George M. Campbell, Robert J. W. Charlton, William N. Chisholm, Elizabeth K. Clark, Margaret R. Clark, John Cottrell, William D. Couper, James Crawford, Elsie V. Crowe, Donald A. Cunningham, Frank Danks, William R. * Second-class honours. † First-class honours.

The following diplomas were awarded :—

Diploma in Tropical Medicine and Hygiene.

Reginald J. Matthews (in absentia).

Diploma in Public Health.

Elizabeth A. Baxendine (in absentia), Elizabeth S. Blair, Jane P. S. Bow, William Boyd, Harry H. Condie, Mary I. S. Cuthbert (in absentia), Edward C. Ellis (in absentia), Jean F. Farquhar, Edith N. Hartley (in absentia), Doris M. Hopps, Janet M. Morton, Agnes M. Ogilvie, Leopold T. Poole, Robert J. Reid, William A. Simpson, Archibald G. H. Smart, Dorothy F. Smith, Vera Thompson, Edgar P. Waters, John H. H. Williams, and Charles R. Wilson.

The Cameron Prize in Practical Therapeutics was awarded to Dr. Harvey Cushing, Moseley Professor of Surgery, Harvard University, and Surgeon-in-Chief, Peter Bent Brigham Hospital, Boston, Mass., for important contributions to the Surgery of the Brain.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held on July 25th Sir Harold J. Stiles, President, in the chair, the 22 successful candidates out of 57 entered, who passed the requisite examinations between March 31st and April 7th were admitted Fellows :—

Robert G. G. Croly, Ronald Cuttle, Hugh Donovan, Samuel E. Duff, Arthur A. Gommell, Peter F. Gow, Pooran C. Kacker, Hilda M. Lazarus, Laura M. Ligertwood, John D. McLaggan, Ebenezer R. Maduram, Sukumar Nag, Ellen L. A. Pateman, Richard H. C. Pryn, Cecil A. Rae, Zelman Schwartz, Louis Sive, Rufus C. Thomas, Allan P. Walden, Hugh A. B. Whitelocke, William R. Williams, and Thomas G. W[illegible]

The following candidates have passed the Final Dental Professional Examination and have been granted the diploma of L.D.S. R.C.S. Edin. :—

William J. Irvine, Schalk W. van der Merwe, Andrew M. Rabie, Annan B. Ness, Hector H. Tomlinson, Alexander R. Gibb, James Baird, Frederick H. Boltman, Clarence G. Morgans, William G. S. Inglis, Susan S. Grandison, Daniel Bell, James Lumsden, William D. McKenzie, George P. Main, and Francis W. Kynoch.

East Suffolk and Ipswich Hospital.—On July 28th the war memorial wing of the hospital at Ipswich was opened by the Duke of Connaught. The new building has been erected at a cost of £67,000, and has increased the permanent accommodation of the hospital from 113 to 270 patients.

University of Manchester.—The Court of the University, on the unanimous recommendation of the Council and Senate, has invited Prof. S. J. Hickson, F.R.S., to continue his tenure of the Beyer Chair of Zoology for a further period of two years from September next. Miss Hilda Linford, M.B., Ch.B. Manch., has been appointed demonstrator in human physiology, and Mr. E. Nevill Willmer, B.A., demonstrator in experimental physiology. The Platt Physiological Scholarship has been awarded to Mr. G. L. Brown.

London (R.F.H.) School of Medicine for Women.—In October will be celebrated the jubilee of this school. The festivities already planned include a public dinner at the Guildhall on Oct. 24th and a festival service at St. Paul's Cathedral on Oct. 25th. It is hoped to raise the sum of £50,000 to endow three chairs of pathology, physiology, and anatomy respectively, to be named after the three pioneer women in medicine, Dr. Elizabeth Blackwell, Dr. Elizabeth Garrett Anderson, and Miss Sophia Jex-Blake. The Queen has headed the list of donations for this purpose with £50, and already eight gifts of £1000 each have been received—four of them from women doctors, and other sums amounting to £1387 have been promised. Donations to the endowment fund should be made payable to the hon. treasurer, Sir Alan G. Anderson, and addressed to the organising secretary, Mrs. K. Balfour Duffus, at 8, Hunter-street, London, W.C. 1.

British Pharmaceutical Conference.—At the sixty-first conference, which was held recently at Bath, under the chairmanship of Mr. Edmund White, the question of whether legislation should be introduced to control the manufacture and sale of patent medicines formed the principal subject of discussion. Mr. Philip F. Rowsell, of Exeter, vice-president of the Pharmaceutical Society of Great Britain, said that it was a matter of urgent public necessity to remedy the more flagrant evils and abuses existing in the sale of patent medicines, for except in so far as patent medicines came within the scope of the Poisons and Pharmacy Act, the trade was subject to no important restrictions at all. And the trade was increasing: in 1914 the receipts from the medicine stamp duty were £360,000, while in 1923 they were nearly £1,250,000. Two possible means of control were suggested: (1) that the manufacturers state the composition of the product on the label, or (2) that there should be some machinery for the control of advertising. One delegate said that professionally the control of the trade would be an advantage, although from the business point of view it would inevitably be detrimental to the pharmacist. Sir William Glyn-Jones, secretary of the Pharmaceutical Society, said that it was the duty of the Pharmaceutical Society to assist the authorities in suppressing abuses of the trade. He added that many more or less patent drugs sold ought to be on the poison schedule. Mr. Sheppard, a delegate from Exeter, urged that the declaration of alcoholic content should be compulsory. The sale of pseudo-medicated wines, he declared, led to a great deal of secret drinking. Finally the subject was referred to the Council of the Pharmaceutical Society for the formation of a scheme and its submission to the branches.

Donations and Bequests.—The late Mr. Bernard Frederick Laporte, of Harpenden, Herts, left by will £250 to Treloar's Cripples' Home; £250 to the Bute Hospital, Luton; and £150 to the Children's Sick and Convalescent Home, London-road, Luton.—Under the will of the late Miss Elizabeth Catherine Theresa Hickes, of Brook-street, Bath, the testatrix left £500 to the Royal Mineral Water Hospital, Bath, and £300 to the Royal United Hospital, Bath; £50 to the Eastern Dispensary, Bath; £50 to the Western Dispensary, Bath; £100 to the Bath District Nurs[illegible]itution; £100 to the Convalescent Home at Cor[illegible] £100 to the Home for Cripples, Prospect-pla[illegible] to the M[illegible]l Mission Fund of the Society for t[illegible]l.—By will the late Mrs. Janet [illegible]ad, Hampstead, N.W., and Leamington. left among other bequests £5000 to St. Columba's Hospital, Avenue-road, N.W.; £5000 to the Hospital for Consumption and Diseases of the Chest, Fulham-road, S.W.: £500 to the London Hospital; £300 to the Faversham Cottage Hospital; and £300 to the Royal Victoria and West Hants Hospital at Boscombe and Bournemouth.—The late Mr. J. C. White, formerly Lord Mayor of Belfast. bequeathed the sum of £100,000, to be devoted to charitable purpose at the discretion of his executors, Messrs. Skinner, McMillan, and Wheeler. The above sum has now been allocated. The Royal Victoria Hospital receives £6000, the Bangor Hospital £5000, and various Belfast Hospitals £1000 each. Several Dublin hospitals and county infirmaries in Northern Ireland also receive the sum of £1000.—The sum of £500 has been presented to the King Edward's Hospital Fund by H.I.H. Tafari Makonnen of Abyssinia.—The British Empire Cancer Campaign has received a further sum of £600 as a result of the special collections organised by the Northamptonshire branch of the British Red Cross Society. The Birmingham branch has remitted an additional £162 from the collections in that city.

Bermondsey Municipal Convalescent Home.—The Minister of Health, Mr. Wheatley, formally opened this home for mothers and babies at Fawkham, Kent, on July 26th. The house—Fairley Grange—has nearly 20 acres of grounds and is the gift of Dr. A. Salter, formerly M.P. for Bermondsey.

The late Dr. W. J. Kerr.—William James Kerr, M.D. Manch., J.P., died at his residence in Rochdale on July 24th at the age of 58. Dr. Kerr received his early education at the Manchester Grammar School and his medical training at Owens College, the Manchester University, and the Royal Infirmary of Manchester, graduating as M.B. and Ch.B. in Victoria University in 1890. He became M.R.C.S. and L.R.C.P. Lond. in the same year. In 1895 he took the degree of M.D. in his University with high commendation. Dr. Kerr began practice in Rochdale in 1896 and speedily built up a large practice, from which he retired a few years ago. Appointed in 1896 an honorary surgeon of the Royal Infirmary, he took an active part in its medical and administrative work, and was president of the medical board during 1911 and 1912, and later a consulting surgeon. He was for 16 years surgeon to the police force of Rochdale. During the war he placed his services at the disposal of the Parliamentary Recruiting Committee, acted as an examiner of recruits, and undertook the duties of factory inspector for Rochdale. His chief interests apart from matters political—for he was an ardent politician—were in public health and sanitary matters, and besides holding medical offices, Dr. Kerr was a member of the town council for ten years, a magistrate, and a J.P. of the borough.

Death of Dr. Edmund M. Smith.—The death of Dr. Edmund Smith occurred on July 23rd, following soon upon his retirement as health officer for the city of York, when occasion was taken to chronicle his work in the public service (The Lancet, June 14th). Edmund Moody Smith was a native of Leeds, received his medical education at Edinburgh University where he graduated M.B., C.M. in 1888 and M.D. in 1891, being awarded the Milner-Fothergill medal. He was a successful general practitioner in York until he became deputy medical officer of health in 1898 and whole-time officer two years later. His appointment as school medical officer followed in 1908, and the special (open-air) schools for mentally defective and physically defective children at Fulford Field remain as monuments of his interest in this direction. Dr. Smith was an active member of the York Musical Society and of the Yorkshire Philosophical Society. He was just 60 years of age and leaves a widow.

The following diplomas were awarded :—

Diploma in Tropical Medicine and Hygiene.

Reginald J. Matthews (in absentia).

Diploma in Public Health.

Elizabeth A. Baxendine (in absentia), Elizabeth S. Blair, Jane P. S. Bow, William Boyd, Harry H. Condie, Mary I. S. Cuthbert (in absentia), Edward C. Ellis (in absentia), Jean F. Farquhar, Edith N. Hartley (in absentia), Doris M. Hopps, Janet M. Morton, Agnes M. Ogilvie, Leopold T. Poole, Robert J. Reid, William A. Simpson, Archibald G. H. Smart, Dorothy F. Smith, Vera Thompson, Edgar P. Waters, John H. H. Williams, and Charles R. Wilson.

The Cameron Prize in Practical Therapeutics was awarded to Dr. Harvey Cushing, Moseley Professor of Surgery, Harvard University, and Surgeon-in-Chief, Peter Bent Brigham Hospital, Boston, Mass., for important contributions to the Surgery of the Brain.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held on July 25th Sir Harold J. Stiles, President, in the chair, the 22 successful candidates out of 57 entered, who passed the requisite examinations between March 31st and April 7th were admitted Fellows :—

Robert G. G. Croly, Ronald Cuttle, Hugh Donovan, Samuel E. Duff, Arthur A. Gommell, Peter F. Gow, Pooran C. Kacker, Hilda M. Lazarus, Laura M. Ligertwood, John D. McLaggan, Ebenezer R. Maduram, Sukumar Nag, Ellen L. A. Pateman, Richard H. C. Pryn, Cecil A. Rae, Zelman Schwartz, Louis Sive, Rufus C. Thomas, Allan P. Walden, Hugh A. B. Whitelocke, William R. Williams, and Thomas G. Wynne.

The following candidates have passed the Final Dental Professional Examination and have been granted the diploma of L.D.S. R.C.S. Edin. :—

William J. Irvine, Schalk W. van der Merwe, Andrew M. Rabie, Annan B. Ness, Hector H. Tomlinson, Alexander R. Gibb, James Baird, Frederick H. Boltman, Clarence G. Morgans, William G. S. Inglis, Susan S. Grandison, Daniel Bell, James Lumsden, William D. McKenzie, George P. Main, and Francis W. Kynoch.

East Suffolk and Ipswich Hospital.—On July 28th the war memorial wing of the hospital at Ipswich was opened by the Duke of Connaught. The new building has been erected at a cost of £67,000, and has increased the permanent accommodation of the hospital from 113 to 270 patients.

University of Manchester.—The Court of the University, on the unanimous recommendation of the Council and Senate, has invited Prof. S. J. Hickson, F.R.S., to continue his tenure of the Beyer Chair of Zoology for a further period of two years from September next. Miss Hilda Linford, M.B., Ch.B. Manch., has been appointed demonstrator in human physiology, and Mr. E. Nevill Willmer, B.A., demonstrator in experimental physiology. The Platt Physiological Scholarship has been awarded to Mr. G. L. Brown.

London (R.F.H.) School of Medicine for Women.—In October will be celebrated the jubilee of this school. The festivities already planned include a public dinner at the Guildhall on Oct. 24th and a festival service at St. Paul's Cathedral on Oct. 25th. It is hoped to raise the sum of £50,000 to endow three chairs of pathology, physiology, and anatomy respectively, to be named after the three pioneer women in medicine, Dr. Elizabeth Blackwell, Dr. Elizabeth Garrett Anderson, and Miss Sophia Jex-Blake. The Queen has headed the list of donations for this purpose with £50, and already eight gifts of £1000 each have been received—four of them from women doctors, and other sums amounting to £1387 have been promised. Donations to the endowment fund should be made payable to the hon. treasurer, Sir Alan G. Anderson, and addressed to the organising secretary, Mrs. K. Balfour Duffus, at 8, Hunter-street, London, W.C. 1.

British Pharmaceutical Conference.—At the sixty-first conference, which was held recently at Bath, under the chairmanship of Mr. Edmund White, the question of whether legislation should be introduced to control the manufacture and sale of patent medicines formed the principal subject of discussion. Mr. Philip F. Rowsell, of Exeter, vice-president of the Pharmaceutical Society of Great Britain, said that it was a matter of urgent public necessity to remedy the more flagrant evils and abuses existing in the sale of patent medicines, for except in so far as patent medicines came within the scope of the Poisons and Pharmacy Act, the trade was subject to no important restrictions at all. And the trade was increasing; in 1914 the receipts from the medicine stamp duty were £360,000, while in 1923 they were nearly £1,250,000. Two possible means of control were suggested: (1) that the manufacturers state the composition of the product on the label, or (2) that there should be some machinery for the control of advertising. One delegate said that professionally the control of the trade would be an advantage, although from the business point of view it would inevitably be detrimental to the pharmacist. Sir William Glyn-Jones, secretary of the Pharmaceutical Society, said that it was the duty of the Pharmaceutical Society to assist the authorities in suppressing abuses of the trade. He added that many more or less patent drugs sold ought to be on the poison schedule. Mr. Sheppard, a delegate from Exeter, urged that the declaration of alcoholic content should be compulsory. The sale of pseudo-medicated wines, he declared, led to a great deal of secret drinking. Finally the subject was referred to the Council of the Pharmaceutical Society for the formation of a scheme and its submission to the branches.

Donations and Bequests.—The late Mr. Bernard Frederick Laporte, of Harpenden, Herts, left by will £250 to Treloar's Cripples' Home: £250 to the Bute Hospital, Luton; and £150 to the Children's Sick and Convalescent Home, London-road, Luton.—Under the will of the late Miss Elizabeth Catherine Theresa Hickes, of Brook-street, Bath, the testatrix left £500 to the Royal Mineral Water Hospital, Bath, and £300 to the Royal United Hospital, Bath: £50 to the Eastern Dispensary, Bath; £50 to the Western Dispensary, Bath: £100 to the Bath District Nursing Institution; £100 to the Convalescent Home at Combe Down: £100 to the Home for Cripples, Prospect-place, Bath; £100 to the Medical Mission Fund of the Society for the Propagation of the Gospel.—By will the late Mrs. Janet Grace Heritage, of Elsworthy-road, Hampstead, N.W., and Leamington, left among other bequests £5000 to St. Columba's Hospital, Avenue-road, N.W.; £5000 to the Hospital for Consumption and Diseases of the Chest, Fulham-road, S.W.; £500 to the London Hospital; £300 to the Faversham Cottage Hospital; and £300 to the Royal Victoria and West Hants Hospital at Boscombe and Bournemouth.—The late Mr. J. C. White, formerly Lord Mayor of Belfast, bequeathed the sum of £100,000, to be devoted to charitable purpose at the discretion of his executors, Messrs. Skinner, McMillan, and Wheeler. The above sum has now been allocated. The Royal Victoria Hospital receives £6000, the Bangor Hospital £5000, and various Belfast Hospitals £1000 each. Several Dublin hospitals and county infirmaries in Northern Ireland also receive the sum of £1000.—The sum of £500 has been presented to the King Edward's Hospital Fund by H.I.H. Tafari Makonnen of Abyssinia.—The British Empire Cancer Campaign has received a further sum of £600 as a result of the special collections organised by the Northamptonshire branch of the British Red Cross Society. The Birmingham branch has remitted an additional £162 from the collections in that city.

BERMONDSEY MUNICIPAL CONVALESCENT HOME.—The Minister of Health, Mr. Wheatley, formally opened this home for mothers and babies at Fawkham, Kent, on July 26th. The house—Fairley Grange—has nearly 20 acres of grounds and is the gift of Dr. A. Salter, formerly M.P. for Bermondsey.

THE LATE DR. W. J. KERR.—William James Kerr, M.D. Manch., J.P., died at his residence in Rochdale on July 24th at the age of 58. Dr. Kerr received his early education at the Manchester Grammar School and his medical training at Owens College, the Manchester University, and the Royal Infirmary of Manchester, graduating as M.B. and Ch.B. in Victoria University in 1890. He became M.R.C.S. and L.R.C.P. Lond. in the same year. In 1895 he took the degree of M.D. in his University with high commendation. Dr. Kerr began practice in Rochdale in 1896 and speedily built up a large practice, from which he retired a few years ago. Appointed in 1896 an honorary surgeon of the Royal Infirmary, he took an active part in its medical and administrative work, and was president of the medical board during 1911 and 1912, and later a consulting surgeon. He was for 16 years surgeon to the police force of Rochdale. During the war he placed his services at the disposal of the Parliamentary Recruiting Committee, acted as an examiner of recruits, and undertook the duties of factory inspector for Rochdale. His chief interests apart from matters political—for he was an ardent politician—were in public health and sanitary matters, and besides holding medical offices, Dr. Kerr was a member of the town council for ten years, a magistrate, and a J.P. of the borough.

DEATH OF DR. EDMUND M. SMITH.—The death of Dr. Edmund Smith occurred on July 23rd, following soon upon his retirement as health officer for the city of York, when occasion was taken to chronicle his work in the public service (THE LANCET, June 14th). Edmund Moody Smith was a native of Leeds, received his medical education at Edinburgh University where he graduated M.B., C.M. in 1888 and M.D. in 1891, being awarded the Milner-Fothergill medal. He was a successful general practitioner in York until he became deputy medical officer of health in 1898 and whole-time officer two years later. His appointment as school medical officer followed in 1908, and the special (open-air) schools for mentally defective and physically defective children at Fulford Field remain as monuments of his interest in this direction. Dr. Smith was an active member of the York Musical Society and of the Yorkshire Philosophical Society. He was just 60 years of age and leaves a widow.

INDEX TO "THE LANCET," VOL. I., 1924.

THE Index and Title-page to Vol. I., 1924, which was completed with the issue of June 28th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers wishing to receive the Indexes regularly as published should indicate this desire.

Appointments.

COHEN, HENRY, M.D. Liverp., has been appointed Assistant Honorary Physician at the Royal Infirmary, Liverpool.

COSENS, W. B., M.R.C.S., L.R.C.P. Lond., an Hon. Consulting Surgeon to the Dorset Mental Hospital.

JENKINS, WINIFRED M., M.B., B.S. Lond., Medical Missionary to the Holy Cross Hospital, Kaffraria, S. Africa, by the S.P.G.

KETTLE, EDGAR HARTLEY, M.D., B.S., of St. Mary's Hospital, Professor of Pathology and Bacteriology in the Welsh National School of Medicine.

Vacancies.

For further information refer to the advertisement columns.

Belfast Joint Nursing and Midwives Council for Northern Ireland.—Examiners.

Birkenhead Education Committee.—Asst. M.O. £600.

Birmingham, Woodlands Open Air Hospital.—H.S. £250.

Cambridge, Addenbrooke's Hospital.—H.S. £130.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. £125. Also Radiologist.

Durham, Holywood Hall Sanatorium, Wolsingham.—Locum Asst. Res. M.O. £40 per month.

Freemasons Hospital and Nursing Home.—Res. M.O. £250.

Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—H.S. £175.

Jersey General Hospital and Poor-law Infirmary.—Res. M.O. £200.

Leeds Public Dispensary.—Sen. Res. M.O. £200.

Melbourne University, Victoria, Australia.—Chair of Pathology. £1200.

Norwich City.—Temp. Asst. School M.O. £11 11s. weekly.

Pontypridd Union, Llwynypia Hospital.—Supt. M.O. £700.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. £100.

Sherwood Forest, Notts, Ransom Sanatorium.—Asst. R.M.O. £375.

Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. £150.

Staffordshire Education Committee.—Asst. Sch. Med. Insp. £600.

West Ham County Borough.—M.O.H. and Chief Sch. M.O. £1500.

THE Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointment: Worksop (Nottingham).

Births, Marriages, and Deaths.

BIRTHS.

HARVEY.—On July 21st, at Lane End, Bournville, Birmingham, the wife of W. F. Harvey, M.A., M.B., of a daughter.

MARTIN.—On July 25th, the wife of James Purdon Martin, M.D., Hunter House, Hunter-street, W.C., of a son.

PATERSON.—On July 28th, at 17, Manchester-street, to Dorothy, wife of Dr. Donald Paterson, of 13, Upper Wimpole-street—a son.

MARRIAGES.

CROCKFORD—BROOKES-SMITH.—On July 21st, at St. John's Church, Holmwood, Allen Lepard Crockford, M.C., M.B., B.Ch., to Doris Ellen Brookes-Smith, younger daughter of Mr. J. H. Brookes-Smith and Mrs. Brookes-Smith, of Brook Meadow, The Holmwood, near Dorking.

ORMSBY—DUGGAN.—On July 25th, at the Chapel Royal, London, after civil ceremony, William Ormsby, late Captain, R.A.M.C., of Rathmoy, Ballina, Co. Mayo, South Ireland, to Mary A. Duggan (*née* Brunt), of Long Sutton, Lincs., near Wisbech.

DEATHS.

BENTHALL.—On July 25th, at Priory-road, N.W., suddenly, Albert Benthall, F.R.C.P.E., aged 74.

ENGLEBACH.—On June 24th, at Cape Town, Harold Augustus Englebach, M.B., B.Ch. T.C.D., Medical Officer of S.A. Police and District Surgeon of Cape Town, aged 52 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

POSTURE IN THE TREATMENT OF DISEASE.

By R. H. Anglin Whitelocke, M.D. Edin., F.R.C.S. Eng.,

SURGEON TO THE RADCLIFFE INFIRMARY, OXFORD.

I PROPOSE to consider the subject of posture more especially as it may concern our dealings with sick children and their management. I shall begin by referring to the practical relationships of posture to ætiology and diagnosis, and later to treatment in various forms of disability in the adult as well as the child.

Posture in Relation to Ætiology and Diagnosis.

It not uncommonly happens that the individual, be he child or adult, assumes instinctively a posture by which his condition may be immediately recognised or which gives important indications as to his future management. The clinician also from time to time is wont to make systematic use of posture to assist him in diagnosis and to aid him in treatment. Posture as a cause of disease is chiefly important in connexion with occupation; thus whilst many persons suffer, and in various ways, from long-continued standing, there are others who are placed equally at a disadvantage from following sedentary occupations. Some who, like colliers and miners, have to work in constrained and unnatural positions are also liable to suffer in consequence. Posture is also of importance as predisposing to certain affections under peculiar and unusual circumstances and in modifying these effects. The recumbent position in low febrile states may lead to hypostatic congestion with its consequences, or to an accumulation of morbid products in the bronchi and lungs which may seriously endanger life. Positions adopted spontaneously by patients often give useful information in diagnosis. In cardiac and pulmonary diseases the individual may be quite unable to lie down owing to the interference with the respiratory functions; he is perforce compelled to sit up, lean forward, or be propped up in bed. In one-sided lung affections he may be only able to lie on one or other side, whilst in heart disease he may be quite unable even to lie on his left. The position generally assumed by the subjects of acute generalised peritonitis is so familiar to us all, and so characteristic, that it needs only to be mentioned to supply us with a very striking example of the value of morbid decubitus as a diagnostic asset. In the various spasmodic attacks of pain frequently associated with this part of the body and known as colic, it is very common to see the patient bending forwards in a doubled-up position and pressing upon the abdomen. In nervous affections also posture aids diagnosis.

It may reveal paralysis in various parts. In cerebral meningitis the subject lies usually in a state of complete flexion with the limbs and body curled forwards and brought together closely, and in cataleptic states any position assumed is usually retained for some considerable though variable time. The posture voluntarily assumed by a limb may give useful information as to local diseases likely to influence it, such as those of the joints, or draw attention to some injury.

Posture as a Therapeutic Measure.

Some of the facts already enumerated demonstrate to us clearly the value of posture also as a therapeutic measure. It will at once be evident that if a wrong posture is the cause of any disability or morbid condition, the first principle in treatment should be to set it right. It is often of great service to allow or even encourage a patient to adopt the position which makes him most comfortable at the particular time. Whenever general prostration and exhaustion are present the recumbent or semi-recumbent posture is clearly indicated as being the most restful, seeing that it involves a minimum of effort. In acute febrile conditions the first essential of treatment is to keep the subject recumbent in bed; and this is also desirable and advisable when excessive fatigue has been endured. In respiratory affections attention to posture is often of much service for symptoms associated with the breathing apparatus, such as pain, cough, and dyspnœa are in many cases peculiarly influenced by change of position. Coughing is often arrested and expectoration made easier by the assumption of a sitting or erect position, whilst the semi-prone or bending-forward position may help much in relieving any pressure upon the tubes.

All cardiac affections are more or less influenced by posture. The horizontal is invaluable in syncopal states since the head at a lower level than the body allows the blood to reach the brain more readily. Whenever the heart is acting feebly from any cause, the act of suddenly raising the patient even into the sitting posture is injudicious and may even cause death. On the other hand, there are conditions of the heart, as when it is dilated, when the individual is quite unable to lie down with any comfort. In such a case it may be quite necessary to have him propped up constantly; the beneficial result being sometimes almost miraculous. The influence of gravitation may be recognised in certain conditions such as dropsical accumulations and generalised anasarca. Even hæmorrhage may be rapidly diminished or even partially arrested on occasions by elevation of the bleeding limb or injured part.

In the treatment of such affections as sea-sickness, giddiness, neuralgia, headache, affections of the head and spine, change of position often brings relief. The varied positions into which the limbs are placed involuntarily to relieve muscular spasm, tension, or pain as the result of disease or injury, must not be lost sight of. In the feeble, and those who have been long confined to bed, it is essential that their positions should be changed periodically to diminish the risks of hypostatic congestion of the lungs and the development of bed-sores. The subjects of chronic cerebral and spinal diseases are also peculiarly liable to these postural disabilities.

Posture in Connexion with Surgical Operations.

Posture is an important factor in post-operative care and treatment. It is certainly one of the most powerful means available both of avoiding complications and hastening recovery. Many and varied are the positions used nowadays, and adapted for preventive and active treatment: (1) the Trendelenburg, or position of raised extremities; (2) the Sims, semi-prone or abdominal; (3) the Fowler, sitting or semi-erect. These may be used separately or in combination.

The Trendelenburg position has been extensively used by surgeons in the United States of America, mainly as a prophylactic agent in assisting to maintain the return of venous blood when for any reason it is hampered, either from a local or general cause. The Sims and Fowler positions are chiefly concerned in establishing and maintaining the drainage of morbid secretions and effusions from wounds or from the cavities and spaces within the body.

Venous thrombosis and its consequences have for many years past supplied a serious cause of anxiety and discomfiture to surgeons. Why the slight anatomical difference between the iliac veins should cause the left vein to be affected in this way at least 20 times more frequently than its fellow, and why the complication should occur usually in the second week after the operation and not before, and in post-operative cases rather than in those without operation, is difficult to understand, and is still to-day without satisfactory explanation. W. Meyer, who 23 years ago published a very interesting paper[1] concerning this serious complication, wrote again recently[2] that in his opinion "treatment by posture will prevent venous thrombosis to a certainty" if carried out regularly and systematically as a post-operative method in the Trendelenburg position. It would be gratifying to feel that so serious a complication might be overcome by such simple means as raising the lower end of the bed upon blocks so that the pelvis of the patient is higher than his thorax. Elevation of the thrombosed limb alone is not recommended. The whole true pelvis must be raised higher than the thorax and the posture adopted soon after the operation and maintained until all risks of thrombosis have passed—that is, for at least ten days. During this time breathing exercises are encouraged as part of the treatment.

The typical Sims's posture, with both arms of the patient pointing forwards while he rests principally on his *right* shoulder, is to my mind the most useful, efficient, and comfortable. If we put the subject of a perforated appendix in Sims's position immediately he is removed from the operating table to his bed, it will be seen that the true pelvis is now the highest point of the drainage system and not the lowest. Blood serum, wound secretions, bile, or any other intra-abdominal extravasated material will in this position run downwards by the shortest possible route, and find ready exit providing an adequate drainage-tube is used. The continuance of this position for the first 18 or 24 hours should be insisted upon—after this, a slight turning to the left is permitted. The usual dorsal decubitus is assumed on the third day, as by that time the discharge will have ceased or become greatly diminished. The foot of the bed should not be raised for the first two or three days, lest perchance any toxic material should flow towards the subphrenic spaces where absorption is known to be most active.

---

[1] Rare Complications after Operations for Appendicitis, Annals of Surgery, May, 1901.

[2] Surg. Clinics of North America, 1921, i., 305.

Disadvantages of Fowler's Position.

Fowler's position, at one time so much extolled and almost universally used, is not now so much in favour. Instituted for the main purpose of establishing drainage and the removal of all toxic fluids towards the pelvis from the upper abdominal peritoneum by means of gravitation, it has been found in practice to present the following disability, which is not present in Sims's or the modified Sims's position. The Fowler position is often very uncomfortable; the patient keeps sliding downwards into the bed and requires to be raised periodically, a manœuvre not without danger. Children will seldom remain in this position for any length of time, and I claim that it is by no means an established fact that it is essential to successful drainage.

I consider that the gravitation theory is quite untenable, and for the following reasons: (1) Drainage of the pouch of Douglas can be quite successfully established through a midline anterior abdominal incision with the drainage-tube placed vertically and the flow against gravity. (2) The thorough drainage of abscesses and other morbid effusions that have escaped into any part of the peritoneal cavity, be it pelvic, appendicular, hepatic, gastric or intestinal, can be effected with the patient lying on his back even continuously, providing certain precautions are taken as to the nature and size of the tube. (3) Children seldom remain in the semi-erect Fowler posture for any length of time, yet who will say that the mortality of appendicitis is any higher in children? (4) Some surgeons who have never allowed the Fowler position at any time in their practice have yet obtained excellent results. That gravitation plays a very important part in abdominal, thoracic, or intracranial drainage is doubtful. The drainage of morbid substances from the body cavities outwards or from one part to another is mainly a vital process. The to-and-fro respiratory movements of the diaphragm and chest wall are undoubtedly the main agents; and drainage is effected by muscular movements rather than gravitation. The peritoneal cavity is normally a closed space with all the contained viscera in close apposition. Every movement of the diaphragm and abdominal muscles in the respiratory efforts presses the viscera, which are elastic and largely compressible, closely together in a to-and-fro rhythmic way. Any fluid or semi-fluid material that is present in, or has found its way into, either the abdominal or thoracic cavities is also similarly compressed. It now only needs a suitable opening, prevented from closing by the insertion of a proper drainage-tube, for automatic drainage to be established. In a similar manner, in the case of joints, the encouragement of movements materially assists drainage. In my opinion, the noticeable reduction in the mortality of appendicitis cases following the introduction of the Fowler and Murphy positions was probably not due to this postural form of treatment so much as to the contemporaneous use of saline injections.

Conclusion.

I wish to emphasise that in the nursing of children posture is especially important, and much, I think, may be gained for them in the future if the nursing profession is taught as a routine the methods of its application. The child instinctively and naturally assumes that position in which he is most comfortable, yet how often is he roused and put into some set position regardless of his protestations, only to lapse again as soon as possible into his old place.

PUBLIC HEALTH IN THE PUNJAB.*

THE population of the Punjab, according to the census of 1921, was 20,517,606, excluding dwellers in military cantonments. Calculated on this basis the birth-rate was 39·3, and the mortality-rate 22·1 per 1000. The health of the province was exceptionally good. Lieut.-Colonel W. H. C. Forster, I.M.S., Director of Public Health, who presents the report for 1922, states that the total death-rate was lower than it had been since 1878. He considers, however, that "if any improvement in the vital statistics is to be obtained, the preventive organisation will have to be expanded, such expansion of necessity connoting a corresponding curtailment of expenditure on the curative organisation." As to this there may be a difference of opinion, but the solution is, of course, that the better the preventive organisation, the less will be the sickness from preventable causes, and therefore the less will be the expenditure needed for treatment.

The *birth-rate* for the province was 39·3 per 1000, as compared with 41·5 in 1921 and 40·0 in the preceding quinquennium. The ratios varied from 21·0 in Simla district, 28·1 in Attock, and 28·8 in Muzaffargarh, to 46·6 in Gurgaon, [illegible] in Amritsar, and 49·1 in Lyallpur. All the districts in Lahore division, and all but one in Multan, showed an increase on the quinquennial average; while all in Rawal Pindi, and all but one in Jullundur, showed a decrease. The ratio for the province, as in the year preceding, was higher than in any other province in India, Central Provinces coming next (35·80); in Bengal the ratio was 27·4.

The *general death-rate* was 22·1 per 1000, a considerable improvement on the ratios for the preceding year (30·1), and for the quinquennium (39·2). The ratio is also lower than that for any other province, except the N.W. frontier (21·68) and Madras (21·0). In the various districts the mortality ranged from 15·2 in Montgomery and 15·4 in Sheikhupura, to 27·0 in Gurgaon and 30·8 in Karnal. The *infantile mortality* (under 1 year) showed a great improvement, 161·35 per 1000 births, as compared with 195·78 in 1921 and 211·23 for the previous five years. Among Mohammedans the ratios were 165·33 and 147·28, among Hindus 179·59 and 161·89, and for Indian Christians 89·57 and 71·26 for male and female infants respectively. For "other classes" the rates are stated as "4000·00 for males and 8400·00 for females." There is here a superabundance of ciphers. Possibly 400 and 840 are the ratios intended, or possibly 40 and 84 per 1000. The actual numbers of deaths are stated in Form IV., p. ix., as 52 males and 20 females.

Cholera had caused 19,215 deaths in the preceding year (0·94 per 1000); during 1922 there were 128 deaths (0·01 per 1000). 16 districts were affected, but only in Ambala was there an epidemic prevalence, with 78 deaths (0·12 per 1000), of which 75 occurred in June, July, and August. The first cases were recorded in Lahore in June, where the disease was introduced from Hardwar; Ludhiana district was next infected, also from Hardwar; then Ambala. The Sun Eclipse Fair at Thanesar (near Ambala) was attended by about 500,000 pilgrims. Cholera broke out, but there were only 16 cases and 8 deaths. This, the report states, speaks highly for the very efficient and elaborate arrangements made by the public health department to meet all contingencies. After the dispersal of the pilgrims one case and one death occurred in Panipat, but otherwise there was no spread of the disease in consequence of this Fair. It is to be hoped that some acknowledgment has been, or will be, made to the medical department for this magnificent success in dealing with a crisis of such urgency.

The *small-pox mortality* fell from 0·22 per 1000 in the previous year, and 0·33 in the quinquennium, to 0·08 (para. 23 and Form VIII.). Simla was quite free from the disease, and in the other districts the death-rate ranged from 0·002 in Karnal and in Ambala, to 0·33 in Lahore and 0·37 in Gujranwala. In the towns the ratio was 0·32, and in the rural areas 0·05; 114 out of the 156 towns escaped the disease altogether; in the remaining 42 there were 659 deaths; 286 of these occurred at Lahore (1·11 per 1000) and 159 at Gujranwala (4·20 per 1000).

There was an increase in *plague mortality* (7837 deaths, as compared with 2896 in 1921), but the death ratio (0·38 per 1000) was much less than the quinquennial average (1·21). Jhelum district suffered most with a ratio of 3·1; no other district exceeded 1·62 (Shahpur), and the whole of Ambala division, as well as Kangra, Hoshiarpur, Ferozepore, and Muzaffargarh districts were entirely free. The most noticeable feature in the history of the disease, says Colonel Forster, was the infection of Murree town. All indications point to the infection being introduced by infected fleas or rats carried in carts loaded with grain, fruit, or vegetables, but the outbreak was soon brought under control, and there were only eight deaths. It may be noted, he continues, that our hill stations have displayed a marked immunity to plague, Kasauli being the only other hill station definitely known to have suffered (in 1904). Rat destruction has been carried out systematically, and on the whole the attitude of the people towards anti-plague measures is improving. *Fever deaths* registered numbered 306,651 (14·95 per 1000, as compared with 20·62 in 1921, and 28·83 for the quinquennium). Karnal district suffered most (24·9), while in the adjoining district of Ambala the ratio was only 12·7 per 1000. Obviously it is not "climate," but local conditions that cause this mortality. This classification of relapsing fever may, however, account for some of this excessive death-rate. In the rural circles the fever mortality was 15·26, ranging from 10·47 in Sheikhupura (Lahore Division) and 10·71 in Jhang (Multan Division), to 19·15 in Mianwali (Rawal Pindi), 19·20 in Dera Ghazi Khan (Multan), and 25·69 in Karnal (Ambala). In the towns the mortality was 12·10. Gidarbaha in Ferozepore district and Chuharkana Mandi in Sheikhupura returned ratios of 0·77 and 0·78 per 1000 respectively; while at Kalabagh in Mianwali district the ratio was 28·11, and at Khudian (in Lahore) 42·16 per 1000.

The deaths recorded from *influenza* numbered 35, of which 13 occurred at Simla, where a mild form was somewhat prevalent throughout the year (115 cases). At Simla also diphtheria was *more* prevalent than usual, 28 cases and 3 deaths; 15 cases occurred at Bishop Cotton's school. The sanitary conditions were inspected, and remedial measures set in progress. Relapsing fever in a mild epidemic form was reported in the Hissar district early in the year; there were 150 cases and 78 deaths, In October it appeared also in a mild form in Rawal Pindi district (104 cases and 35 deaths); in the same month the disease broke out in a severe form in Muzaffagarh, but apparently was not recognised as such until December. "The extreme poverty and filthiness of the people rendered disinfection over such a wide area extremely difficult; most of the people had no clothes other than the vermin-infected rags that they wore." A rapid expansion of the system of district health officers is required to ensure prompt recognition of the disease. The adoption of a system of itinerating medical officers to give arsenical treatment is recommended. Typhus fever occurred in small outbreaks in Rawal Pindi district and in the Bhajji State (Simla Hills), but was quickly overcome; no typhoid prevalence is mentioned. A notable improvement is recorded in regard to *dysentery* and *diarrhœa*, the mortality from which was 0·34 per 1000, as compared with 0·58 in 1921 and 0·54 for the quinquennium. The ratio varied from 0·02 in Hoshiarpur and Sheikhupura districts, to 1·37 in Simla and 2·69 in Rawal Pindi. Respiratory diseases also showed a decrease, the mortality being 1·95 per 1000, against 2·72 and 2·47 for the preceding year and the quinquennium respectively. In Ambala and in Gurdaspur districts the ratios were 8:74 and 5·31. In Muzaffargarh and Shahpur only 0·21, and in Montgomery only 0·19 per 1000. *Deaths from injury* in the province numbered 6153, being in a ratio of 0·30, as compared with 0·32 per 1000 in 1921 and 0·34 for the quinquennium; most of these were from accident (4091). *Rabies* caused 130 deaths. At the Kasauli Pasteur Institute 1939 patients underwent treatment, against 1677 in the preceding year; 192 were Europeans. There were 7 deaths and 4 failures among Indians, apparently none among Europeans.

---

* Lahore: Government Press. 1923.

In the appendix it is stated that "the present annual grant of 4 lakhs falls far short of the needs of the Sanitary Board, which was petitioned for aid during the year to the extent of 9 lakhs. On account of financial stringency no increase in the allotment could be made, but when circumstances permit, it is hoped that the Board will be accorded generous treatment."

Punjab Lunatic Asylum.

In the report for 1922* it is stated that the total number of inmates fell from 1248 in 1920 and 1204 in 1921 to 1168 in 1922, the decline being due to decrease in admissions from overseas; but the daily average strength rose from 862·81 in 1920 to 864·6 in 1921, and 867·2 in 1922. The report states that the accommodation of the asylum is taxed to its utmost at present. The percentage of cures to average strength was 13·03, as compared with 12·40 in 1920 and 15·96 in 1921. The death-rate, 6·69 per cent. of strength, showed a great improvement on the ratios for 1921 (11·22) and 1920 (12·63). Of the total 1168 cases, 139 (all males) were suffering from the effects of *Cannabis indica;* 90 were epileptics (71 males), 84 idiots (55 males), and 23 imbeciles (20 males); while 175 (162 males) are returned under melancholia. Among the 342 admissions during the year *Cannabis indica* insanity heads the list with 55 cases (all males), as stated on p. xxiii. (Statement vii.); in Statement vi. the number admitted is shown as 47. As there are three obvious press errors in this page (xvii.), it may be presumed that the figure in Statement vii. is more likely to be correct. In regard to the general health of the inmates, dysentery and diarrhœa, as usual, accounted for most of the admissions to hospital (83 cases and 7 deaths). In 1921 there had been 142 admissions for these diseases, with 21 deaths. A tuberculous section of the asylum was opened in 1921, and better facilities are now available for the diagnosis and treatment of this disease in its early stages; 52 cases were treated during the year. This report is signed by Col. R. Heard, I.M.S., Inspector-General of Civil Hospitals for the province, who states that Major H. W. V. Cox, I.M.D., was in charge until Nov. 13th and administered the asylum with zeal and marked ability. He was succeeded by Capt. C. J. L. Patch, M.C., I.M.S.

WHY IT CANNOT BE PUBLISHED

In the June number of the *Nation's Health*, an American journal, there is a paper with the above heading, in which Lowell V. Collins and Susa P. Moore have attempted to analyse the controlling factors in the acceptance and rejection of manuscripts. They refer to a famous writer, whose name they withhold, who traced much of his success to an early understanding of the significance of the rejection slips with which he, like all young writers, was submerged. With rare perspicuity he came to the conclusion that the fault lay with himself. They suggest to writers on health subjects that they consider the time and labour required by the readers of their writings as well as the time and labour required by the author. In this connexion they refer to the following instructive incident. A short article on a health subject was written hurriedly and then read by the author at a normal rate which took 15 minutes. He then revised and condensed it, taking 40 minutes in the process. It was now found that his message could be read in about 10 minutes, and that the style of his article had considerably improved. After publication it was estimated that 25,000 persons would read the article, and each would save five minutes because of the author's revision. "In this way, more than 2000 hours of profitless reading was avoided at the cost of 40 minutes' revision." Reading aloud his own manuscript is a discipline which, it is urged, every author should inflict on himself, and the advice is none the less good because so old. The procedure serves to emphasise the clumsiness of reiteration, the importance of proper punctuation, or the need for rearrangement. Potential authors are reminded that health articles should sparkle with interest and originality, having the power to pique curiosity and hold interest continuously, and here we feel definitely antagonistic to the mentors, for articles written with the intention to sparkle, to hold, or to pique form the gloomiest literature that masquerades as scientific.

PENAL REFORM.

We have received a copy of the third issue of the *Howard Journal*, the organ of the Howard League for Penal Reform, which is described as "a review of modern methods for the prevention and treatment of crime and juvenile delinquency." This number contains original articles on such subjects as crime and insanity, and the medical examination of delinquents, a long review of the report of the Prison Commission, foreign news, and book reviews; the total contents run to rather more than 80 pages. The Howard League stands for an educative and humane rather than a punitive policy in prison administration, and favours the abolition of the death penalty. Particular emphasis is laid on the need for medical examination and treatment in the numerous cases where crime is possibly attributable to mental defect or disorder.

A PROTECTIVE SHIELD FOR WOMEN SUFFERING FROM MENORRHAGIA.

Women with menorrhagia often suffer more from the dread of insufficient protection than from the physical discomfort of excessive menstrual flow, and a form of neurasthenia amounting to an anxiety state occasionally results in those who cannot lie up at these times. Nash's self-fixing "Surmeto" Hygienic Mene Shield is an all-rubber shield, easily cleaned, rather larger than an ordinary sanitary towel, in which the latter can be securely fixed through strips of rubber without difficulty, and no further anxiety as to possible leakage need occur. The shield can be obtained from chemists or drapers, or direct from the proprietors, Messrs. Nash and Sons, 29, Kyverdale-road, London, N. 16, for 2*s*. 6*d*.

UNSIGHTLY WARTS.

To the Editor of The Lancet.

Sir,—I should be grateful if any fellow practitioner could advise as to the treatment of small, multiple soft warts on the back of the hand. Cauterisation with nitric or glacial acetic acid produces very unsightly scars with the larger ones, and does not affect the smaller ones, only causing burns of the surrounding skin surface. Lime-water taken internally has had no effect. The warts are unsightly, and cause annoyance to the patient.

I am, Sir, yours faithfully,
G. S. Sander, M.D.

Claremont, Wateringbury, Kent, July 27th, 1924.

ARTIFICIAL RESPIRATION.

To the Editor of The Lancet.

Sir,—I have read with interest Dr. E. Seaborn's notes on the above subject in The Lancet of July 19th, and being a devoted M.O. to an ambulance division I fancy the same would find acceptance as an "occasional lecture." I notice that there is no allusion to "Laborde's method," and we teach that it is useful in cases (1) of injury of chest and shoulder-girdle, (2) in children, (3) in electric shock, and as supplementary to other methods under various circumstances. Moreover, personally, being a sufferer from bronchial asthma with dyspnœa, I have fancied that (in private of course) the forcible protrusion of the tongue a few times resulted in ampler inspiration. Whether this is merely due to the after-effect of holding the breath while the tongue is being protruded, or due to the nervous mechanism, I do not like definitely to assert.

I am, Sir, yours faithfully,
H. C. Lamport.

Lancaster, July 25th, 1924.

An Address

[ABRIDGED]

ON

PROGRESS AND PROSPECTS IN CHEMOTHERAPY.

Delivered before the Section of Physiology of the British Association at Toronto on August 6th, 1924,

BY H. H. DALE, C.B.E., M.D. CAMB., F.R.S.,

PRESIDENT OF THE SECTION; DIRECTOR OF THE DEPARTMENT OF BIOCHEMISTRY AND PHARMACOLOGY AT THE NATIONAL INSTITUTE OF MEDICAL RESEARCH, HAMPSTEAD, LONDON.

THE THEORETICAL ORIGIN OF CHEMOTHERAPY.

CHEMOTHERAPY may be defined as the specific treatment of infections by artificial remedies. The object of those who study it is to find new remedies which will cure or arrest diseases due to infections, not by alleviating the symptoms or invigorating the patient, but by directly and specifically suppressing the infection. Chemotherapy, in this wide sense, is not entirely of recent growth. When the natives of Peru discovered the value in fevers of the cinchona bark, which the Jesuits brought to Europe in the seventeenth century, they had found a specific remedy for malaria, which is still the best available. Similarly the natives of Brazil had found in ipecacuanha, which reached Europe shortly after cinchona, a remedy for amœbic dysentery better than any other which our modern systematic and scientific efforts have produced. Modern chemistry, indeed, has separated the alkaloids from these drugs, and has made it possible to identify among them the actively therapeutic constituents; protozoology has revealed the nature of the infections. We know now that cinchona owes its curative action chiefly to quinine and quinidine, and that they act as specific exterminators of the malaria parasites, and not simply as remedies for fevers *in general*; and we know that ipecacuanha owes its action to emetine and cephaline, and that these act as exterminators of the entamœba causing tropical dysentery, and not simply as symptomatic remedies for dysenteries of any kind. But chemistry has produced no better remedy for malaria than quinine, or for amœbic dysentery than emetine; and the method by which either of these alkaloids cuts short the infection by a particular parasite, the nature of its specific action remains a fascinating problem.

The modern development of chemotherapy, as a new department in therapeutic science, claiming the coöperation of parasitologists, micro-biologists, and synthetic chemists, did not take origin, however, simply from the study of these traditional remedies. It may be regarded rather as an outcome of the study of the natural antibodies. The investigation of these natural antagonists to infection produced a new therapeutic ideal. Not only had they shown themselves to have an intensly specific affinity for the infecting organism of the toxin which caused their production, they were also perfectly harmless to the patient, behaving, in relation to his organism, as normal constituents of his body fluids and tissues. Ehrlich aptly compared them to magic bullets, constrained by a charm to fly straight to their specific objective, and to turn aside from anything else in their path.

Of the artificial remedies, on the other hand, which man had empirically discovered, even of drugs like those just mentioned as being specific for certain infections, the best that could be hoped was that they would eliminate the parasite before they poisoned the patient. And thus, when the limitations of natural immunity were becoming clearer, when it was realised that to certain forms of infection, several of which had proved to be infections by protozoa, the body was unable to produce antibodies of sufficient potency to eliminate the infection and leave the patient immune, the question arose whether, with the new and growing powers afforded by synthetic chemistry, man could not so far rival Nature's achievements as to produce, in the laboratory, substances specifically adapted to unite with and kill the protoplasm of these parasites, as the natural antibodies united with that of others, and to leave the tissues of the patient similarly unaffected. The ideal of this new and systematic chemotherapy, as the imaginative genius of Paul Ehrlich conceived it, was to be the production by synthesis of substances with a powerful specific affinity for, and a consequent toxic action on, the protoplasm of the parasites, and none for that of the host—of substances, to use Ehrlich's own terminology, which should be maximally parasitotropic and minimally organotropic.

I want to invite attention to the results which, during the last 20 years, have been produced under the stimulus of this bold conception; not, indeed, to attempt a survey or summary of all that has been done, but, in the light of a few of the suggestive facts which have emerged, to consider how far this hypothesis has justified itself, and whether it can be accepted as a safe guide to future progress, as it has undoubtedly provided the initiative and working basis for much of what has been accomplished hitherto. Before we deal with some of the actual results obtained, it may be well to consider a little more closely what Ehrlich's working hypothesis involved. The problem was to discover, by chemical synthesis, a compound which, in virtue of its chemical structure, should have a maximal affinity for the protoplasm of a microscopic parasite, such as a trypanosome, and a minimal affinity for that of the host's body cells. These affinities were pictured by Ehrlich, in the terms of his side-chain theory, as determined by certain side-chains of the complex protein molecule, or chemoreceptors, which endowed the protoplasm with specific combining properties. When it is remembered that knowledge of the chemistry of the protoplasm of a trypanosome is almost nil, and that what little we do know suggests that *it is very similar* to that of our own cells, it will be admitted that the enterprise was one calling for scientific courage and imagination in the highest degree. Complete failure would not have been surprising; the matter for surprise, and for admiration, is that so large a measure of practical success should, at the end of two decades, already claim record.

TRYPANOSOMES AND SPIROCHÆTES.

The Action of Dyes and Analogous Compounds.

The investigations leading, in the last few years, to a clear promise, at last, of the successful treatment of the diseases in man and animals due to infections with trypanosomes had at least two different starting-points, the action of dyes and the action of arsenic. Ehrlich's early interest in the synthetic dyes, and his observations of the curiously selective distribution which they often exhibited among the cells and tissues of the body, naturally suggested the possibility of finding in this group a substance which would selectively fix itself to the parasite and poison its protoplasm without injuring that of the host.

[Dr. Dale then described the steps whereby the compounds "trypan red" and "trypan blue" were arrived at by Ehrlich and Shiga, and Mesnil and Nicolle respectively. He proceeded :]

"Trypan blue" is the only one of the dyes which has hitherto had a genuine practical success in the treatment of a protozoal infection, not indeed by a trypanosome, but by an intracorpuscular parasite of the genus piroplasma, which infects dogs and cattle. This successful application of trypan blue to an animal disease has a special interest, in that it resulted from the joint labours of last year's President of this section, Prof. G. H. Nuttall, with a Canadian collaborator, Dr. Hadwen.

We may turn aside at this point to inquire how far the results even of these earlier investigations corresponded with the theory which gave them their impetus. Did these dyes really act by selectively staining and killing the parasites and leaving the host's cells untouched? The evidence was certainly not in favour of such a view. One point, however, appeared very significant, and it is met repeatedly in studying the action of effectively chemotherapeutic substances—namely, that the trypanosomes treated with the dye in vitro, though neither obviously stained nor visibly harmed, had lost their power of infection, and died out promptly if introduced into the body of a mouse. Under such conditions only minimal traces of the dye are introduced into the animal, and we are left with a series of alternative possibilities. It is possible that sufficient dye has been taken up by the trypanosomes to kill them eventually, the period of survival in vitro being inadequate to display its action; or that trypan red is converted by the influence of the body fluids and tissues into something which is effectively lethal for the parasite; or, again, that the effect of the drug is not directly to kill the trypanosomes, but, leaving their individual vitality and motility unimpaired, so to modify them that they have lost the power of rapidly reproducing themselves and invading the fluids and tissues of the mouse's body—in other words, have lost that complex of adjustments to the various factors of the host's natural resistance which we crudely summarise as "virulence." Such possibilities involve either storage or modification of the dye by the host's tissues, or their essential coöperation in its curative effect.

One other active dye must be mentioned as providing the link with a recent, most important advance. Mesnil and Nicolle in 1906 made some promising experiments with a dye, Afridol violet, which differed from any previously tested in that its central nucleus was diamino-diphenyl-urea. From this time onwards there was no further public indication of progress along these lines until 1920, when Handel and Joetten published the results obtained with a remarkable substance which, as the result of some 15 years of continuous work by their scientific staff, had been introduced by the great dye and chemical firm of Bayer. This substance, which is not a dye, but the colourless, water-soluble salt of a complex sulphonic acid, has hitherto been known as Bayer "205," and, for reasons which need not concern us, the firm decided not to publish its formula. There is a reasonable probability that its identity has now been settled by the recent work of Fourneau and his co-workers in the Pasteur Institute, who made and investigated an extensive series of compounds of this general type, and found one, which they numbered "309," which conspicuously excelled all others, even those closely related to it, in the favourable ratio which it displayed, between a just toxic dose and that which caused a trypanosome infection in mice to disappear. At least it may be said that, if Mr. Fourneau has not identified Bayer "205," he has discovered another compound having very similar, and probably as valuable, properties. The most remarkable property of "205" is the long persistence of its effect. A dose injected into a mouse, a rabbit, or a rat will not only free the animal, if already infected, from trypanosomes in a few days, but will also render it resistant to such infection for a period of weeks or even months. During that period its serum, or extracts from certain of its organs, exhibit a curative action if injected into another animal infected with trypanosomes.

Though there seems no reason to doubt that this substance has cured a number of cases of African sleeping-sickness in man, even some in which the disease was well advanced and in which all previously known remedies had failed, the mode of its action still presents a number of attractive obscurities. One thing seems perfectly clear—namely, that the action is a very complex one, involving the coöperation, in some way, of the host. For here again it is found that the curative action, on infections by the same strain of trypanosomes, varies enormously with the species infected, a mouse being cured with ease, an ox or a horse with difficulty or not at all. A curious fact is that the rapidly progressive and fatal infections produced in mice by certain pathogenic trypanosomes are easily and certainly cured, while the apparently harmless natural infection, seen in many wild rats, by *T. lewisi* is not affected at all. Then there are some curious records of treatment in man, in which the symptoms of sleeping-sickness have disappeared, but the trypanosomes are still found in the cerebro-spinal fluid suggesting that, though the parasites have not been killed, they have lost their virulence and their power of invading the brain substance.

It would be both useless and presumptuous for a mere onlooker to speculate in detail on the significance, for the curative action of "205," of properties which are only now beginning to be investigated. One conclusion, however, I think we are entitled to draw. It is sufficiently evident that here is no question of a substance curing simply on account of its affinity for parasites and lack of affinity for the host's tissues. What direct action on the parasite "205" itself may possess has still to be demonstrated; we may feel reasonably certain, on the other hand, that its affinities for the constituents of the host's blood and tissues play an important part in its remarkable and peculiar curative properties.

Derivatives of Arsenic.

In the case of the other series of investigations which I mentioned, that dealing with the organic derivatives of arsenic, we find again many difficulties, in the way of the simple theory, of a cure due to distribution by chemical affinities. None of the compounds of this series, which have reached practical trial and success in the treatment of spirochætal or trypanosomal infections, atoxyl, salvarsan, or tryparsamide, has a directly lethal action on the parasites in dilutions at all comparable to those which can be safely and effectively produced in the body of the host. The paradox of this direct inertness of atoxyl, the starting-point of the series, seemed to be explained when Ehrlich showed that its reduction to the corresponding arsenoxide produced a substance with an intense directly lethal action on trypanosomes. Similarly the partial oxidation of salvarsan, to the corresponding arsenoxide, produced a substance having the intensely lethal action on spirochætes or trypanosomes in vitro which salvarsan itself conspicuously and paradoxically lacked. In these cases, we may make the supposition, which Voegtlin and his co-workers especially have recently supported by detailed evidence, that the reduction or oxidation effected by contact with the tissues is the essential preliminary to the curative action; a supposition which, it will be noted, again introduces the host as an essential participant in the cure. The fact that the administration of these relatively inactive predecessors is therapeutically more effective than the injection of the directly active oxides derived from them, would then be explained on the assumption that the slow liberation of these latter in the body, at a rate which never produces a high concentration, provides the optimum condition for their persistent action on the parasites without danger to the host. This slow and persistent liberation of the directly active substance would be favoured by the physical properties of salvarsan, which at the reaction of the body is practically insoluble, and must be rapidly deposited after injection.

In their recent work on the action of tryparsamide, the compound, prepared by Jacobs and Heidelberger at the Rockefeller Institute, which has shared with Bayer "205" the credit of making the eventual conquest of African sleeping-sickness a hopeful possibility, Brown and Pearce find it necessary to introduce yet other considerations to explain its effects. Tested by Ehrlich's therapeutic index—the ratio between the lowest curative and the highest non-toxic dose—it gives a relatively unfavourable figure. Brown and Pearce practically abandon the attempt to account for its action on the supposition that it directly kills the parasites, and attribute its value largely to its power of penetrating easily into the tissues and reinforcing there the processes of natural resistance.

Action of Bismuth.

Another conception of the mode of action of these arsenical remedies, also involving a direct participation in the host's tissues, was put forward by Levaditi. He found that from atoxyl a directly parasiticidal preparation could be obtained by incubating it with an emulsion of fresh liver substance. As the first step, therefore, in the curative action of atoxyl, he postulated a combination of its reduction product with some constituent of the liver or other tissue, giving rise to the essential curative complex, which he named "trypanotoxyl." Levaditi's observations were explained by Ehrlich and Roehl as due simply to the reducing action of the liver substance on atoxyl; but it would be difficult to apply this explanation to the quite recently published observations by Levaditi and his colleagues on the mode of action of bismuth in curing spirochætal infections. A sodium potassium bismuthyl tartrate—a bismuth analogue of tartar emetic—had been found to have valuable curative properties in syphilis and other spirochætal infections. Later, various other bismuth salts, bismuth suboxide, and even finely divided metallic bismuth, were found to produce similar effects. According to Levaditi and Nicolau, these preparations have, by themselves, a relatively weak action, or none at all, on the spirochætes outside the body. If they are mixed, however, with a cell-free extract of liver, which is itself harmless to spirochætes, the mixture, after incubation, acquires a potent spirochæticidal action. The possibility of a mere reducing action of the liver extract seems here to be excluded, since bismuthous oxide, or metallic bismuth itself, yields a spirochæticidal mixture, containing Levaditi's hypothetical "bismoxyl," when incubated with the liver extract. If these observations are confirmed, there will be a strong indication that some cell-constituent enters into the composition of, or is essential to the formation of, the directly active substance from any of the derivatives of arsenic, antimony, or bismuth, as a preliminary to its action on an infection due to a trypanosome or a spirochæte. Again we have evidence of an organotropic property of the remedy, as an essential condition of its activity.

Resistant Strains of Trypanosomes.

In the phenomena of the acquisition of resistance by a strain of infecting trypanosomes to a particular curative drug we meet again with facts which can only with the greatest difficulty be reconciled with the assumption that the drug directly attacks the parasites. It was found, for example, that if a mouse infected with trypanosomes received an incompletely effective series of doses of atoxyl, the trypanosomes appearing in the blood at each relapse were more and more resistant to the drug, until they could not be caused to disappear by any dose of atoxyl which the mouse would tolerate. The strain, having once acquired this resistance, would retain it, on passage through an indefinitely long series of mice, without further treatment. Mesnil and Brimont, however, made the remarkable observation that, if the strain of trypanosomes was transferred to a rat, it immediately became in that animal susceptible again to treatment with atoxyl, remained so as long as it was kept in rats, to reacquire its old resistance to atoxyl as soon as it was retransferred to mice. Such a fact seems to be not at all explicable on the theory that the directly active agent, to which the trypanosome becomes resistant, is a mere reduction product of atoxyl; it is much more easily reconciled with a mechanism such as that described by Levaditi, in which a constituent of the host's tissues enters into the formation of the trypanocidal substance. We can imagine the trypanosome becoming immune to Levaditi's mouse-trypanotoxyl, and remaining susceptible to the corresponding rat-product.

SUGGESTED REACTION OF AN ARSENOXIDE WITH A SULPHYDRILE COMPOUND.

A recent suggestion by Voegtlin has interest in making at least an attempt at interpretation of these phenomena in definite biochemical terms. Voegtlin and his co-workers point out that arsenious oxide and its derivatives readily combine with substances containing a sulphydrile grouping, and find that the toxic action of the organic arsenoxides on trypanosome and mammal alike is depressed by the simultaneous injection of excess of various sulphydrile compounds.

$$\text{R·As} : \text{O} + \frac{\text{HS·R}}{\text{HS·R}} = \text{R·As}\begin{matrix}\diagup\text{S·R}\\ \diagdown\text{S·R}\end{matrix} + \text{H}_2\text{O}.$$

The work of Gowland Hopkins showing the importance of one such sulphydrile compound, reduced glutathione, in the hydrolytic oxidation-reduction processes of the cell suggests to Voegtlin that a combination with such groups, and consequent suppression of this vital function, may explain the toxic and curative actions of the arsenical derivatives, and that a formation by the trypanosome of the sulphydrile compound, in excess of its vital need, may be the basis of acquired resistance. If certain dyes similarly affect this cellular oxidation system, the production under their influence of strains of trypanosomes resistant to arsenic would also be explained. So stated the suggestion leaves many aspects of the problem still unconsidered; but it may at least be allowed the merit of an attempt to interpret the action of these drugs in terms of known biochemical facts.

EMETINE AND DYSENTERY.

To turn to another example of a chemotherapeutic problem, I may mention briefly some results obtained some years ago by Mr. Clifford Dobell and myself in an attempt to explore the curative action of emetine and the other alkaloids of ipecacuanha in amœbic dysentery with a view to finding a more effective treatment. At the time when we took up the problem it seemed simple. Leonard Rogers had recorded that the amœbæ obtained from a case of amœbic dysentery, and treated in vitro with emetine, were rapidly killed by the alkaloid in dilutions as high as one part in 100,000. This seemed to explain the action of emetine as a simple and direct one on the parasites, and to provide a rapid method for testing a series of compounds for their therapeutic possibilities. We failed, however, as other observers before and since have done, to confirm the observation; on the contrary, we found that the dysenteric amœbæ, obtained from cats secondarily infected, or, in a control observation, directly from man, were surprisingly insusceptible to the action of emetine, living for hours in concentrations much greater than the highest which they would tolerate of other alkaloids, which had no curative action in dysentery. One of the other natural alkaloids of ipecacuanha, methyl-psychotrine, and certain artificial derivatives of emetine, were much more effective in killing the amœbæ in the test-tube, and at the same time were practically devoid of the characteristic toxicity of emetine and cephæline for mammals and for man. Here, on the classical assumption of chemotherapy, should have been ideal remedies for amœbic infection—substances much more parasitotropic and much less organotropic than those already known to be effective. Yet each of them in turn, when administered to patients suffering from amœbic dysentery, in doses much larger than those in which emetine could be tolerated, produced no effect whatever on the dysentery, which promptly cleared up when emetine was subsequently given. Among the members of this group of alkaloids which were tried, the curative effect seemed to be proportional rather to their toxic and nauseating action on the patient, than to their lethal action on the isolated amœbæ. Yet emetine and cephæline are not mere symptomatic remedies; they definitely stop the progress of infection by the amœbæ, and, properly administered, eliminate them altogether from the body.

We may turn aside at this point to inquire how far the results even of these earlier investigations corresponded with the theory which gave them their impetus. Did these dyes really act by selectively staining and killing the parasites and leaving the host's cells untouched? The evidence was certainly not in favour of such a view. One point, however, appeared very significant, and it is met repeatedly in studying the action of effectively chemotherapeutic substances—namely, that the trypanosomes treated with the dye in vitro, though neither obviously stained nor visibly harmed, had lost their power of infection, and died out promptly if introduced into the body of a mouse. Under such conditions only minimal traces of the dye are introduced into the animal, and we are left with a series of alternative possibilities. It is possible that sufficient dye has been taken up by the trypanosomes to kill them eventually, the period of survival in vitro being inadequate to display its action; or that trypan red is converted by the influence of the body fluids and tissues into something which is effectively lethal for the parasite; or, again, that the effect of the drug is not directly to kill the trypanosomes, but, leaving their individual vitality and motility unimpaired, so to modify them that they have lost the power of rapidly reproducing themselves and invading the fluids and tissues of the mouse's body—in other words, have lost that complex of adjustments to the various factors of the host's natural resistance which we crudely summarise as "virulence." Such possibilities involve either storage or modification of the dye by the host's tissues, or their essential coöperation in its curative effect.

One other active dye must be mentioned as providing the link with a recent, most important advance. Mesnil and Nicolle in 1906 made some promising experiments with a dye, Afridol violet, which differed from any previously tested in that its central nucleus was diamino-diphenyl-urea. From this time onwards there was no further public indication of progress along these lines until 1920, when Handel and Joetten published the results obtained with a remarkable substance which, as the result of some 15 years of continuous work by their scientific staff, had been introduced by the great dye and chemical firm of Bayer. This substance, which is not a dye, but the colourless, water-soluble salt of a complex sulphonic acid, has hitherto been known as Bayer "205," and, for reasons which need not concern us, the firm decided not to publish its formula. There is a reasonable probability that its identity has now been settled by the recent work of Fourneau and his co-workers in the Pasteur Institute, who made and investigated an extensive series of compounds of this general type, and found one, which they numbered "309," which conspicuously excelled all others, even those closely related to it, in the favourable ratio which it displayed, between a just toxic dose and that which caused a trypanosome infection in mice to disappear. At least it may be said that, if Mr. Fourneau has not identified Bayer "205," he has discovered another compound having very similar, and probably as valuable, properties. The most remarkable property of "205" is the long persistence of its effect. A dose injected into a mouse, a rabbit, or a rat will not only free the animal, if already infected, from trypanosomes in a few days, but will also render it resistant to such infection for a period of weeks or even months. During that period its serum, or extracts from certain of its organs, exhibit a curative action if injected into another animal infected with trypanosomes.

Though there seems no reason to doubt that this substance has cured a number of cases of African sleeping-sickness in man, even some in which the disease was well advanced and in which all previously known remedies had failed, the mode of its action still presents a number of attractive obscurities. One thing seems perfectly clear—namely, that the action is a very complex one, involving the coöperation, in some way, of the host. For here again it is found that the curative action, on infections by the same strain of trypanosomes, varies enormously with the species infected, a mouse being cured with ease, an ox or a horse with difficulty or not at all. A curious fact is that the rapidly progressive and fatal infections produced in mice by certain pathogenic trypanosomes are easily and certainly cured, while the apparently harmless natural infection, seen in many wild rats, by *T. lewisi* is not affected at all. Then there are some curious records of treatment in man, in which the symptoms of sleeping-sickness have disappeared, but the trypanosomes are still found in the cerebro-spinal fluid suggesting that, though the parasites have not been killed, they have lost their virulence and their power of invading the brain substance.

It would be both useless and presumptuous for a mere onlooker to speculate in detail on the significance, for the curative action of "205," of properties which are only now beginning to be investigated. One conclusion, however, I think we are entitled to draw. It is sufficiently evident that here is no question of a substance curing simply on account of its affinity for parasites and lack of affinity for the host's tissues. What direct action on the parasite "205" itself may possess has still to be demonstrated; we may feel reasonably certain, on the other hand, that its affinities for the constituents of the host's blood and tissues play an important part in its remarkable and peculiar curative properties.

Derivatives of Arsenic.

In the case of the other series of investigations which I mentioned, that dealing with the organic derivatives of arsenic, we find again many difficulties, in the way of the simple theory, of a cure due to distribution by chemical affinities. None of the compounds of this series, which have reached practical trial and success in the treatment of spirochætal or trypanosomal infections, atoxyl, salvarsan, or tryparsamide, has a directly lethal action on the parasites in dilutions at all comparable to those which can be safely and effectively produced in the body of the host. The paradox of this direct inertness of atoxyl, the starting-point of the series, seemed to be explained when Ehrlich showed that its reduction to the corresponding arsenoxide produced a substance with an intense directly lethal action on trypanosomes. Similarly the partial oxidation of salvarsan, to the corresponding arsenoxide, produced a substance having the intensely lethal action on spirochætes or trypanosomes in vitro which salvarsan itself conspicuously and paradoxically lacked. In these cases, we may make the supposition, which Voegtlin and his co-workers especially have recently supported by detailed evidence, that the reduction or oxidation effected by contact with the tissues is the essential preliminary to the curative action; a supposition which, it will be noted, again introduces the host as an essential participant in the cure. The fact that the administration of these relatively inactive predecessors is therapeutically more effective than the injection of the directly active oxides derived from them, would then be explained on the assumption that the slow liberation of these latter in the body, at a rate which never produces a high concentration, provides the optimum condition for their persistent action on the parasites without danger to the host. This slow and persistent liberation of the directly active substance would be favoured by the physical properties of salvarsan, which at the reaction of the body is practically insoluble, and must be rapidly deposited after injection.

In their recent work on the action of tryparsamide, the compound, prepared by Jacobs and Heidelberger at the Rockefeller Institute, which has shared with Bayer "205" the credit of making the eventual conquest of African sleeping-sickness a hopeful possibility, Brown and Pearce find it necessary to introduce yet other considerations to explain its effects. Tested by Ehrlich's therapeutic index—the ratio between the lowest curative and the highest non-toxic dose—it gives a relatively unfavourable figure. Brown and Pearce practically abandon the attempt to account for its action on the supposition that it directly kills the parasites, and attribute its value largely to its power of penetrating easily into the tissues and reinforcing there the processes of natural resistance.

Action of Bismuth.

Another conception of the mode of action of these arsenical remedies, also involving a direct participation in the host's tissues, was put forward by Levaditi. He found that from atoxyl a directly parasiticidal preparation could be obtained by incubating it with an emulsion of fresh liver substance. As the first step, therefore, in the curative action of atoxyl, he postulated a combination of its reduction product with some constituent of the liver or other tissue, giving rise to the essential curative complex, which he named "trypanotoxyl." Levaditi's observations were explained by Ehrlich and Roehl as due simply to the reducing action of the liver substance on atoxyl; but it would be difficult to apply this explanation to the quite recently published observations by Levaditi and his colleagues on the mode of action of bismuth in curing spirochætal infections. A sodium potassium bismuthyl tartrate—a bismuth analogue of tartar emetic—had been found to have valuable curative properties in syphilis and other spirochætal infections. Later, various other bismuth salts, bismuth suboxide, and even finely divided metallic bismuth, were found to produce similar effects. According to Levaditi and Nicolau, these preparations have, by themselves, a relatively weak action, or none at all, on the spirochætes outside the body. If they are mixed, however, with a cell-free extract of liver, which is itself harmless to spirochætes, the mixture, after incubation, acquires a potent spirochæticidal action. The possibility of a mere reducing action of the liver extract seems here to be excluded, since bismuthous oxide, or metallic bismuth itself, yields a spirochæticidal mixture, containing Levaditi's hypothetical "bismoxyl," when incubated with the liver extract. If these observations are confirmed, there will be a strong indication that some cell-constituent enters into the composition of, or is essential to the formation of, the directly active substance from any of the derivatives of arsenic, antimony, or bismuth, as a preliminary to its action on an infection due to a trypanosome or a spirochæte. Again we have evidence of an organotropic property of the remedy, as an essential condition of its activity.

Resistant Strains of Trypanosomes.

In the phenomena of the acquisition of resistance by a strain of infecting trypanosomes to a particular curative drug we meet again with facts which can only with the greatest difficulty be reconciled with the assumption that the drug directly attacks the parasites. It was found, for example, that if a mouse infected with trypanosomes received an incompletely effective series of doses of atoxyl, the trypanosomes appearing in the blood at each relapse were more and more resistant to the drug, until they could not be caused to disappear by any dose of atoxyl which the mouse would tolerate. The strain, having once acquired this resistance, would retain it, on passage through an indefinitely long series of mice, without further treatment. Mesnil and Brimont, however, made the remarkable observation that, if the strain of trypanosomes was transferred to a rat, it immediately became in that animal susceptible again to treatment with atoxyl, remained so as long as it was kept in rats, to reacquire its old resistance to atoxyl as soon as it was retransferred to mice. Such a fact seems to be not at all explicable on the theory that the directly active agent, to which the trypanosome becomes resistant, is a mere reduction product of atoxyl; it is much more easily reconciled with a mechanism such as that described by Levaditi, in which a constituent of the host's tissues enters into the formation of the trypanocidal substance. We can imagine the trypanosome becoming immune to Levaditi's mouse-trypanotoxyl, and remaining susceptible to the corresponding rat-product.

SUGGESTED REACTION OF AN ARSENOXIDE WITH A SULPHYDRILE COMPOUND.

A recent suggestion by Voegtlin has interest in making at least an attempt at interpretation of these phenomena in definite biochemical terms. Voegtlin and his co-workers point out that arsenious oxide and its derivatives readily combine with substances containing a sulphydrile grouping, and find that the toxic action of the organic arsenoxides on trypanosome and mammal alike is depressed by the simultaneous injection of excess of various sulphydrile compounds.

$$R\cdot As:O + \frac{HS\cdot R}{HS\cdot R} = R\cdot As\begin{array}{l}\diagup S\cdot R\\ \diagdown S\cdot R\end{array} + H_2O.$$

The work of Gowland Hopkins showing the importance of one such sulphydrile compound, reduced glutathione, in the hydrolytic oxidation-reduction processes of the cell suggests to Voegtlin that a combination with such groups, and consequent suppression of this vital function, may explain the toxic and curative actions of the arsenical derivatives, and that a formation by the trypanosome of the sulphydrile compound, in excess of its vital need, may be the basis of acquired resistance. If certain dyes similarly affect this cellular oxidation system, the production under their influence of strains of trypanosomes resistant to arsenic would also be explained. So stated the suggestion leaves many aspects of the problem still unconsidered; but it may at least be allowed the merit of an attempt to interpret the action of these drugs in terms of known biochemical facts.

EMETINE AND DYSENTERY.

To turn to another example of a chemotherapeutic problem, I may mention briefly some results obtained some years ago by Mr. Clifford Dobell and myself in an attempt to explore the curative action of emetine and the other alkaloids of ipecacuanha in amœbic dysentery with a view to finding a more effective treatment. At the time when we took up the problem it seemed simple. Leonard Rogers had recorded that the amœbæ obtained from a case of amœbic dysentery, and treated in vitro with emetine, were rapidly killed by the alkaloid in dilutions as high as one part in 100,000. This seemed to explain the action of emetine as a simple and direct one on the parasites, and to provide a rapid method for testing a series of compounds for their therapeutic possibilities. We failed, however, as other observers before and since have done, to confirm the observation; on the contrary, we found that the dysenteric amœbæ, obtained from cats secondarily infected, or, in a control observation, directly from man, were surprisingly insusceptible to the action of emetine, living for hours in concentrations much greater than the highest which they would tolerate of other alkaloids, which had no curative action in dysentery. One of the other natural alkaloids of ipecacuanha, methyl-psychotrine, and certain artificial derivatives of emetine, were much more effective in killing the amœbæ in the test-tube, and at the same time were practically devoid of the characteristic toxicity of emetine and cephæline for mammals and for man. Here, on the classical assumption of chemotherapy, should have been ideal remedies for amœbic infection—substances much more parasitotropic and much less organotropic than those already known to be effective. Yet each of them in turn, when administered to patients suffering from amœbic dysentery, in doses much larger than those in which emetine could be tolerated, produced no effect whatever on the dysentery, which promptly cleared up when emetine was subsequently given. Among the members of this group of alkaloids which were tried, the curative effect seemed to be proportional rather to their toxic and nauseating action on the patient, than to their lethal action on the isolated amœbæ. Yet emetine and cephæline are not mere symptomatic remedies; they definitely stop the progress of infection by the amœbæ, and, properly administered, eliminate them altogether from the body.

Yet another puzzling observation, made by Dobell and myself, was that an amœbic infection which readily yielded to treatment with emetine in man was entirely uninfluenced by emetine when transferred to the cat. In no way is it possible to account for these facts without admitting a coöperation of the patient's tissues in the curative action; nor, with that admission, can we do more than consider possibilities. We only know that the truly parasitic *Entamœba histolytica*, which cannot live without invading the tissues, can be checked in this invasion and eliminated from the body by administering emetine, while other entamœbæ, which live on fæcal debris, remain unharmed. Whether the tissues are so altered that the amœbæ cannot invade them, or the amœbæ, without being directly killed, are so weakened in virulence that they cannot invade the tissue and obtain their food, but succumb in face of the normal resisting powers of the host, are possibilities on which we can only speculate, and no method of bringing them to the test of experiment has yet been found.

The work of Morgenroth and his co-workers, extending now over more than a decade, has again led them to emphasise, in connexion with the curative action of substances which they have examined, a fixation to the cells and tissues of the host, a definitely organotropic property, as an important factor in the effect. Two examples may be mentioned.

Quinine and Malaria.

One of the earliest of chemotherapeutic discoveries, that of the cure of malaria by quinine, had never been satisfactorily explained. There was no evidence establishing even a probability that quinine, in such concentrations as can be tolerated in the blood of the living subject, would directly kill the malarial plasmodia, especially if these were partly screened from its action by their position in the interior of the red corpuscles. Morgenroth, from the results of his determinations by biological methods of the distribution of quinine in blood, is led to the conception of quinine as acting on malaria, in virtue of its fixation by the red corpuscles, either killing the trophozoites in their interior, or blocking the entry into them of the merozoites of the asexual cycle. On this latter supposition it will be seen that quinine would act, not by killing the malarial parasites, but by rendering the blood unfitted for their multiplication. They are supposed to fall a prey to the natural defensive substances in the plasma, because a film of quinine denies them access to the red corpuscles, in the interior of which they could continue their development in safety. There are discrepancies between Morgenroth's determinations of the distribution of quinine in favour of the red corpuscles and those obtained by direct chemical means which would still need to be reconciled before either theory of the curative process in malaria could be fully accepted. Meanwhile, these suggestions are of interest as another example of the need found more and more by workers in this field, to regard an organotropic property of a drug, not as detrimental to its curative action, but as an essential factor in the chemotherapeutic process.

Remedies for Bacterial Infections.

This same property of fixing themselves to the red blood corpuscles or to the connective tissue has been observed by Morgenroth and his co-workers with the higher homologues of quinine, ethylhydrocupreine ("optochin"), and octylhydrocupreine ("vuzin"), and with the dyes of the acridine series, with which they have obtained promising results in the treatment of bacterial infections. In the treatment of pneumococcus infections by optochin several factors, other than those of immediately lethal action of the alkaloid on the pneumococci, appear to be concerned. Evidence was obtained by Moore, for example, which suggested that the defensive reaction of the host was an essential factor in the cure, optochin, in doses inadequate to kill the pneumococci, rendering them liable to the action of specific antibodies; and some experiments of Felton and Dougherty suggest that an excessive dose of an alkaloid of this class, by suppressing the natural defensive reaction, may even allow the fatal spread of an infection which a lower dose would cure. Morgenroth, on the other hand, emphasises the part played by the organotropic properties of optochin and vuzin in enabling the red corpuscles to act as carriers of the drug to the point of action, and the connective tissues to form local depôts of it.

An acridine dye, named trypaflavin, was under study in Ehrlich's laboratory in 1914 as a trypanocidal remedy, and was found during the war by Browning and his co-workers to have valuable properties as an antiseptic for infected wounds and mucous membranes, for which, under the name "acriflavine" it is still used. Since the war other dyes of this series have been investigated by Morgenroth and his school, and one of them, called "rivanol" (2-ethoxy 6, 9 diamino acridine), is stated to be particularly effective as a tissue antiseptic, especially in conditions of spreading infection due to streptococci. In the case of "rivanol" also, evidence has been brought forward that it is fixed by the red corpuscles and the subcutaneous tissues, protected thereby from excretion, or held at the point where its curative action is required. From these body cells it is suggested that the dye is gradually given up to the cocci, on which its action is exerted, by a process called "transgression" by Morgenroth. This is a process by which a substance is passed from one medium to another, when both have strong affinities for it, through a layer of an intervening medium for which it has no affinity, and in which it may be almost insoluble. In this process of depôt formation and gradual liberation of the active substance we are concerned with a phenomenon which certainly has a widespread importance for chemotherapeutic action. We have earlier seen evidence of such fixation and gradual release in the cases of Bayer "205" and salvarsan.

Another suggestive feature of the action of "rivanol" on streptococcal infections is that such organisms as escape the immediately lethal effect of the dye appear to have lost their hæmolytic properties, and to have been modified into a relatively avirulent strain.

Conclusion.

We have considered but a few examples of the directions in which chemotherapeutic investigation has proved practically fruitful, including some in which it shows, at the moment, the most hopeful signs of progress. If one considers any one group of investigations by itself, one may easily feel at the same time elated by the practical success obtained in the cure of some infection which but a few years ago seemed beyond the reach of treatment, and depressed by the disharmony between the results of experiment and the theoretical conceptions, hitherto available, of the nature of the chemotherapeutic process. Some of the most notable practical triumphs in this field have resulted, not from experimental investigations based on theory, but from an almost empirical trial, on human patients suffering from one type of infection, of a remedy which had experimentally shown promising results in infections of a different, and sometimes of a widely different, type. The partial success of tartar emetic in trypanosome infections might have justified a hope that it would have some effect in kala-azar, but hardly a prediction of its really remarkable efficacy in that previously intractable form of infection. Still less would it have justified expectation of the brilliant success of this same drug in infections by the schistosoma or bilharzia worm, which but recently seemed almost beyond the hope of any kind of treatment. With such instances in mind, one might, but a year or two ago, have been tempted to suggest that the attempts at theoretical investigation of the intimate mechanism of the chemotherapeutic process had contributed little to the practical achievements, and that a reasonably intelligent empiricism was still the safest guide. I do not think that the suggestion would even then have been defensible, and it would assuredly have been stultified by the results of the past few years. Patient, systematic exploration, by routes of which the initial sections were already mapped in the early days of chemotherapy, has in these recent years again led to results of major importance, both for practical therapeutics and for the theoretical basis of future advance. That the original theoretical framework begins to show itself inadequate for the expanding fabric is good reason for its reconstruction; but we may well beware of hasty and wholesale rejection, remembering that it served the early builders well. I think that it is especially encouraging to note that though in the action of almost every remedy which has proved its value in the specific cure of infection there are features which cannot be interpreted by a strict application of Ehrlich's distribution hypothesis, the discrepancies begin to show a new congruity among themselves. Repeatedly we find phenomena which point to the need of modifying the theoretical structure in the same direction. The conception of a remedy not killing the parasites immediately, but modifying their virulence, or lowering their resistance to the body's natural defences; of a remedy not acting as such, but in virtue of the formation from it in the body of some directly toxic product, either by a modification of its structure or by its union with some tissue constituent; of an affinity of the remedy for certain cells of the host's body, leading to the formation of a dépôt from which, in long persistent, never dangerous concentration, the curative substance is slowly released; all these conceptions present themselves again and again as necessary for our present rationalisation of the effects observed. It can hardly be doubted that they will potently influence the methods by which, in the immediate future, new and still better specific remedies are sought. But though our practical aim, in relation to the affinities of a remedy for the parasite and for the host's tissues, may be radically changed, the meaning of these specific affinities, so delicately adjusted to a precise molecular pattern, remains dark. Ehrlich's chemoreceptors may no longer satisfy us, but we have nothing equally definite to replace them. I have endeavoured to indicate what seem to me hopeful signs of new contacts between biochemistry and chemotherapy. There is promise, in another direction, that at least some aspects of the problem of immune specificity are being brought within the scope of strictly chemical investigation, as in the recent work of Avery and Heidelberger, on the constituent of a pneumococcus which combines with the specific precipitin. As in Ehrlich's pioneer work in chemotherapy, it can hardly be doubted that an increased understanding of the meaning of immune specificity, which but a short while ago might have seemed hopelessly beyond the range of attack by chemical weapons, will still influence ideas, and help to shape the course of further investigations on the chemotherapeutic process. As the biological complexity of the problem is realised, it becomes increasingly a matter for wonder and admiration that so much of practical value has already been achieved—the treatment of the spirochætal infections, syphilis, yaws, and relapsing fever revolutionised: leishmania infections, kala-azar and Baghdad boil, and bilharzia infections, which crippled the health of whole populations in countries such as Egypt, now made definitely curable: trypanosome infections, such as the deadly African sleeping-sickness, after years of alternating promise and disappointment, brought now at last within the range of effective treatment. And if such results have already been attained, in a period during which practice has often and inevitably outrun theory, we may well be hopeful for a future in which fuller understanding should make for more orderly progress.

GASTRIC FUNCTION BEFORE AND AFTER GASTRO-JEJUNOSTOMY.

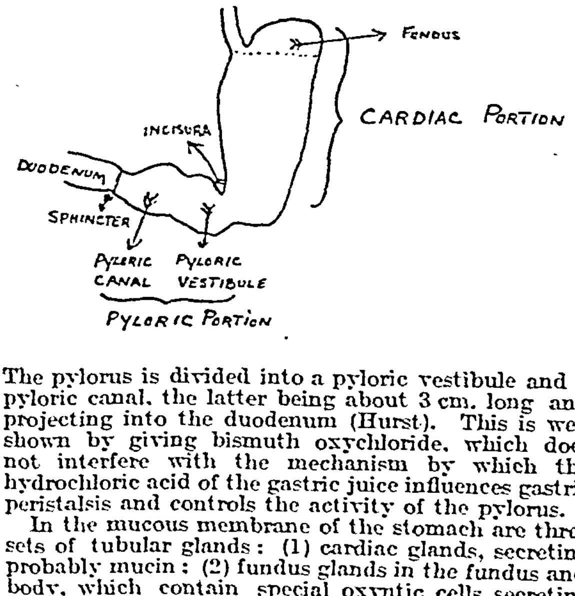
By T. G. D. BONAR, M.D., B.S. LOND., F.R.C.S. EDIN.,
RESIDENT SURGICAL OFFICER, GUY'S HOSPITAL.

IN considering the question of gastric function before and after gastro-jejunostomy—an operation done for a pathological lesion of the stomach or duodenum—normal gastric function must be mentioned.

Anatomy and Physiology.

The stomach has two main functions: (1) the secretion of gastric juice for digestive purposes; (2) peristaltic action to pass the partially digested food into the duodenum, where it is further digested by the pancreatic juice assisted by bile. If some pathological lesion of the stomach or duodenum exists, then presumably there will be some upset of these functions depending on (*a*) the position of the lesion, (*b*) the size of the lesion, (*c*) the nature of the lesion. Normally, the stomach varies in size and situation, depending on the position of the patient. Usually the greater curvature is below the umbilicus in the upright, and just above it in the horizontal posture. The fundus lies above the cardiac orifice and contains gas; the body is almost vertical, and to the left of the mid-line. The body is distinguished from the pyloric portion at the incisura angularis (Fig. 1).

FIG. 1.



The pylorus is divided into a pyloric vestibule and a pyloric canal, the latter being about 3 cm. long and projecting into the duodenum (Hurst). This is well shown by giving bismuth oxychloride, which does not interfere with the mechanism by which the hydrochloric acid of the gastric juice influences gastric peristalsis and controls the activity of the pylorus.

In the mucous membrane of the stomach are three sets of tubular glands: (1) cardiac glands, secreting probably mucin; (2) fundus glands in the fundus and body, which contain special oxyntic cells secreting hydrochloric acid; (3) pyloric glands, which probably produce a hormone causing the continued secretion of gastric juice by the fundus glands.

The secretion of gastric juice is largely under control of the central nervous system via the vagi, which serve as one of the factors to gastric secretion, the other being a chemical stimulant which enables gastric juice to be secreted as long as digestion lasts. Normally, gastric juice contains about 0·2 per cent. HCl; gastric chyme passes through the pylorus into the duodenum, and the HCl in the duodenum helps to regulate the pyloric sphincter (Von Mering). Normally, the epithelial cells of the stomach secrete an antibody—antipepsin—which prevents the stomach being digested.

Hurst has shown by X rays that when empty the upper third of the stomach contains gas. Food when swallowed causes relaxation of the stomach and the

Yet another puzzling observation, made by Dobell and myself, was that an amœbic infection which readily yielded to treatment with emetine in man was entirely uninfluenced by emetine when transferred to the cat. In no way is it possible to account for these facts without admitting a coöperation of the patient's tissues in the curative action; nor, with that admission, can we do more than consider possibilities. We only know that the truly parasitic *Entamœba histolytica*, which cannot live without invading the tissues, can be checked in this invasion and eliminated from the body by administering emetine, while other entamœbæ, which live on fæcal debris, remain unharmed. Whether the tissues are so altered that the amœbæ cannot invade them, or the amœbæ, without being directly killed, are so weakened in virulence that they cannot invade the tissue and obtain their food, but succumb in face of the normal resisting powers of the host, are possibilities on which we can only speculate, and no method of bringing them to the test of experiment has yet been found.

The work of Morgenroth and his co-workers, extending now over more than a decade, has again led them to emphasise, in connexion with the curative action of substances which they have examined, a fixation to the cells and tissues of the host, a definitely organotropic property, as an important factor in the effect. Two examples may be mentioned.

QUININE AND MALARIA.

One of the earliest of chemotherapeutic discoveries, that of the cure of malaria by quinine, had never been satisfactorily explained. There was no evidence establishing even a probability that quinine, in such concentrations as can be tolerated in the blood of the living subject, would directly kill the malarial plasmodia, especially if these were partly screened from its action by their position in the interior of the red corpuscles. Morgenroth, from the results of his determinations by biological methods of the distribution of quinine in blood, is led to the conception of quinine as acting on malaria, in virtue of its fixation by the red corpuscles, either killing the trophozoites in their interior, or blocking the entry into them of the merozoites of the asexual cycle. On this latter supposition it will be seen that quinine would act, not by killing the malarial parasites, but by rendering the blood unfitted for their multiplication. They are supposed to fall a prey to the natural defensive substances in the plasma, because a film of quinine denies them access to the red corpuscles, in the interior of which they could continue their development in safety. There are discrepancies between Morgenroth's determinations of the distribution of quinine in favour of the red corpuscles and those obtained by direct chemical means which would still need to be reconciled before either theory of the curative process in malaria could be fully accepted. Meanwhile, these suggestions are of interest as another example of the need found more and more by workers in this field, to regard an organotropic property of a drug, not as detrimental to its curative action, but as an essential factor in the chemotherapeutic process.

REMEDIES FOR BACTERIAL INFECTIONS.

This same property of fixing themselves to the red blood corpuscles or to the connective tissue has been observed by Morgenroth and his co-workers with the higher homologues of quinine, ethylhydrocupreine ("optochin"), and octylhydrocupreine ("vuzin"), and with the dyes of the acridine series, with which they have obtained promising results in the treatment of bacterial infections. In the treatment of pneumococcus infections by optochin several factors, other than those of immediately lethal action of the alkaloid on the pneumococci, appear to be concerned. Evidence was obtained by Moore, for example, which suggested that the defensive reaction of the host was an essential factor in the cure, optochin, in doses inadequate to kill the pneumococci, rendering them liable to the action of specific antibodies; and some experiments of Felton and Dougherty suggest that an excessive dose of an alkaloid of this class, by suppressing the natural defensive reaction, may even allow the fatal spread of an infection which a lower dose would cure. Morgenroth, on the other hand, emphasises the part played by the organotropic properties of optochin and vuzin in enabling the red corpuscles to act as carriers of the drug to the point of action, and the connective tissues to form local depôts of it.

An acridine dye, named trypaflavin, was under study in Ehrlich's laboratory in 1914 as a trypanocidal remedy, and was found during the war by Browning and his co-workers to have valuable properties as an antiseptic for infected wounds and mucous membranes, for which, under the name "acriflavine" it is still used. Since the war other dyes of this series have been investigated by Morgenroth and his school, and one of them, called "rivanol" (2-ethoxy, 6, 9 diamino acridine), is stated to be particularly effective as a tissue antiseptic, especially in conditions of spreading infection due to streptococci. In the case of "rivanol" also, evidence has been brought forward that it is fixed by the red corpuscles and the subcutaneous tissues, protected thereby from excretion, or held at the point where its curative action is required. From these body cells it is suggested that the dye is gradually given up to the cocci, on which its action is exerted, by a process called "transgression" by Morgenroth. This is a process by which a substance is passed from one medium to another, when both have strong affinities for it, through a layer of an intervening medium for which it has no affinity, and in which it may be almost insoluble. In this process of depôt formation and gradual liberation of the active substance we are concerned with a phenomenon which certainly has a widespread importance for chemotherapeutic action. We have earlier seen evidence of such fixation and gradual release in the cases of Bayer "205" and salvarsan.

Another suggestive feature of the action of "rivanol" on streptococcal infections is that such organisms as escape the immediately lethal effect of the dye appear to have lost their hæmolytic properties, and to have been modified into a relatively avirulent strain.

CONCLUSION.

We have considered but a few examples of the directions in which chemotherapeutic investigation has proved practically fruitful, including some in which it shows, at the moment, the most hopeful signs of progress. If one considers any one group of investigations by itself, one may easily feel at the same time elated by the practical success obtained in the cure of some infection which but a few years ago seemed beyond the reach of treatment, and depressed by the disharmony between the results of experiment and the theoretical conceptions, hitherto available, of the nature of the chemotherapeutic process. Some of the most notable practical triumphs in this field have resulted, not from experimental investigations based on theory, but from an almost empirical trial, on human patients suffering from one type of infection, of a remedy which had experimentally shown promising results in infections of a different, and sometimes of a widely different, type. The partial success of tartar emetic in trypanosome infections might have justified a hope that it would have some effect in kala-azar, but hardly a prediction of its really remarkable efficacy in that previously intractable form of infection. Still less would it have justified expectation of the brilliant success of this same drug in infections by the schistosoma or bilharzia worm, which but recently seemed almost beyond the hope of any kind of treatment. With such instances in mind, one might, but a year or two ago, have been tempted to suggest that the attempts at theoretical investigation of the intimate mechanism of the chemotherapeutic process had contributed little to the practical achievements, and that a reasonably intelligent empiricism was still the safest guide. I do not think that the suggestion would even then have been defensible, and it would assuredly have been stultified by the results of the past few years. Patient, systematic exploration, by routes of which the initial sections were already mapped in the early days of chemotherapy, has in these recent years again led to results of major importance, both for practical therapeutics and for the theoretical basis of future advance. And if such results have already been attained, in a period during which practice has often and inevitably outrun theory, we may well be hopeful for a future in which fuller understanding should make for more orderly progress.

GASTRIC FUNCTION BEFORE AND AFTER GASTRO-JEJUNOSTOMY.

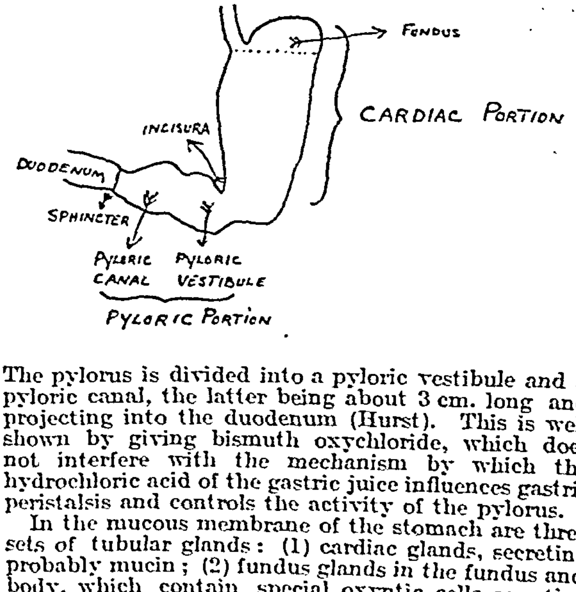
BY T. G. D. BONAR, M.D., B.S. LOND.,
F.R.C.S. EDIN.,
RESIDENT SURGICAL OFFICER, GUY'S HOSPITAL.

IN considering the question of gastric function before and after gastro-jejunostomy—an operation done for a pathological lesion of the stomach or duodenum—normal gastric function must be mentioned.

Anatomy and Physiology.

The stomach has two main functions: (1) the secretion of gastric juice for digestive purposes; (2) peristaltic action to pass the partially digested food into the duodenum, where it is further digested by the pancreatic juice assisted by bile. If some pathological lesion of the stomach or duodenum exists, then presumably there will be some upset of these functions depending on (*a*) the position of the lesion, (*b*) the size of the lesion, (*c*) the nature of the lesion. Normally, the stomach varies in size and situation, depending on the position of the patient. Usually the greater curvature is below the umbilicus in the upright, and just above it in the horizontal posture. The fundus lies above the cardiac orifice and contains gas; the body is almost vertical, and to the left of the mid-line. The body is distinguished from the pyloric portion at the incisura angularis (Fig. 1).

FIG. 1.



The pylorus is divided into a pyloric vestibule and a pyloric canal, the latter being about 3 cm. long and projecting into the duodenum (Hurst). This is well shown by giving bismuth oxychloride, which does not interfere with the mechanism by which the hydrochloric acid of the gastric juice influences gastric peristalsis and controls the activity of the pylorus.

In the mucous membrane of the stomach are three sets of tubular glands: (1) cardiac glands, secreting probably mucin; (2) fundus glands in the fundus and body, which contain special oxyntic cells secreting hydrochloric acid; (3) pyloric glands, which probably produce a hormone causing the continued secretion of gastric juice by the fundus glands.

The secretion of gastric juice is largely under control of the central nervous system via the vagi, which serve as one of the factors to gastric secretion, the other being a chemical stimulant which enables gastric juice to be secreted as long as digestion lasts. Normally, gastric juice contains about 0·2 per cent. HCl; gastric chyme passes through the pylorus into the duodenum, and the HCl in the duodenum helps to regulate the pyloric sphincter (Von Mering). Normally, the epithelial cells of the stomach secrete an antibody—antipepsin—which prevents the stomach being digested.

Hurst has shown by X rays that when empty the upper third of the stomach contains gas. Food when swallowed causes relaxation of the stomach and the systematic movements commence, which first begin gently, but gradually increase in intensity. Cannon showed that the pyloric end is the seat of continuous peristalsis as long as food is present, and that immediately after a small portion of food is passed into the duodenum the pylorus goes into tonic activity. Note, however, that the fundus and body do not undergo rhythmic contractions, but maintain strong tonicity so that the cardiac portion of the stomach exerts a positive pressure on the food contained. So long as food is solid the pyloric sphincter will not relax, and Cannon showed that a piece of solid food knocking against the open pyloric sphincter at once caused its closure. Therefore, for the pyloric sphincter to open, the chyme must be sufficiently acid and sufficiently thin. Associated with the absence of gastric secretion the pyloric sphincter becomes relaxed, and pancreatic juice, bile, and intestinal secretion flow back into the stomach (Boldireff).

Potential Cause of Gastric Ulcer.

From some of the observations a potential cause of gastric ulcer may be inferred. Ulcers commonly occur as pyloric ulcers. Now the mucous membrane of the stomach in the neighbourhood of the pylorus is particularly liable to injury during digestion, and the injured or inflamed cells, being no longer able to produce antipepsin, are rapidly digested and so form an early ulcer. This may cause a hypersecretion of acid by reflex stimulation, and give rise to the so-called "hunger pain," which is probably a spasmodic contraction of the pylorus brought about by the acidity. In gastric carcinoma there is a hypochlorhydria, and this is due to the destruction of the cells producing the gastric hormone with a lack of stimulation of the oxyntic cells and the formation of less acid. In the pyloric vestibule food is most intimately mixed with gastric juice, and it is here that solid food is most likely to injure the mucous membrane of the stomach and so predispose to the formation of ulcer.

Methods of Investigation.

The methods used in the investigation of patients before and after gastro-jejunostomy were the fractional test-meal and X ray examination. Rehfuss[1] was the pioneer of this method, and the technique carried out was the modification of Rehfuss's method suggested by Ryle,[2] where, for the test-meal two tablespoonfuls of oatmeal were added to a quart of water, which was boiled down to a pint and then strained—the resulting gruel being given to the patient about 9.30 A.M. after a 12-hours' fast from food and fluid. In every case an attempt was made to obtain resting juice by getting the patient to swallow the Einhorn's tube first. Every quarter of an hour up to, on an average, three hours (or until no more fluid could be extracted) a sample of the meal was removed for estimation of HCl and total acidity. The materials used for this purpose were N/10 sodium hydroxide and dimethylaminoazobenzol and phenolphthalein as indicators. Sugar and starch were tested for by Fehling's solution and iodine, and their absence was used as an indication as to when the stomach was empty. The presence of bile, mucus, or blood was also noted. In this manner the acidity in the stomach was known at any given moment, and could be compared with the acidity after operation at the same time interval. This method was considered to be more accurate and valuable in this research work than the old test-meal of tea and toast as recommended by Ewald. Ryffel,[3] comparing the two types of meal, suggested the greater value of Ewald's technique for cases of carcinoma of the stomach. Certainly with Ewald's meal mineral chlorides can be estimated, which would be extremely difficult in the case of the fractional meal, but, as will be shown later, carcinoma of the stomach is diagnosable by means of the fractional test-meal in a high percentage of cases.

All patients were submitted to an X ray examination before and after the operation, the material used being bismuth oxycarbonate made into an emulsion with water. Before operation, with a view to diagnosis of the pathological lesion present, the condition of the stomach as to size, shape, position, and tone was noted. After operation the effect of the gastro-jejunostomy on the stomach as regards size, shape, position, and tone was observed, care being taken to ascertain whether any of the opaque meal was leaving the stomach via the pylorus as well as by the stoma. It is to be noted that X ray examination may give a false impression concerning the rate of emptying of the stomach, for the heavy weight of the meal is sufficient to allow it to fall through the gastro-jejunostomy opening, especially if the patient be examined in the erect posture.

Ryle,[4] working in conjunction with Bennett, made investigations on a hundred normal students. They showed that there was a marked uniformity in gastric motility during health, and that cases with high acidity tended to empty more slowly than the average, whilst those with low acidity and especially with achlorhydria emptied more rapidly. They came to the conclusion, however, that a so-called normal curve could be given for 80 per cent. of cases, and that this could be taken as a standard (Fig. 3). This will be used later for comparison with the cases of gastro-jejunostomy that have been investigated. One other important point to notice is that, according to Bell,[5] the acidity of the gastric secretion does not tend to become less with advancing age, and the acid curve for women is usually lower than that for men.

The type of patient examined was that entering the ordinary hospital wards, and the second series of investigations were carried out about eight to nine months after the patient was discharged from hospital —i.e., about ten months after operation.

In many cases, where patients had been apparently relieved completely of symptoms, it was extraordinarily difficult to get them to submit to these further investigations, some refusing both the fractional test-meal and the X ray examination, some the fractional test-meal only. This unfortunately makes a difference in the percentage results of the cases examined. Patients who were examined were those who had gastric, pyloric, or duodenal ulcers; those with pyloric stenosis due to ulcer or carcinoma, and cases of carcinoma of the stomach. A number were also examined who had undergone an excision of the ulcer alone or with gastro-jejunostomy. In the series also are some cases of gastrectomy with anastomosis between the stomach and jejunum, and some cases of gastro-jejunal and jejunal ulcers. In all cases which were examined at operation notes were carefully made as to the site, size, and nature of the lesion, also as to the type of operation performed.

Statistics.

The ages of people suffering from ulcer lay between 21 and 50, and the average age of cases who had gastric ulcers was 35 years; pyloric ulcers, 30 years; and duodenal ulcers, 29 years. The average ages of patients who suffered from pyloric stenosis due to ulcer was 39; due to carcinoma, 52 (Fig. 2).

Altogether 100 cases were examined, with the following results: (1) Gastric ulcers, 14; (2) pyloric ulcers, with or without stenosis, 30; (3) duodenal ulcers, 33; (4) carcinoma of the stomach, 20; (5) gastro-jejunal or jejunal ulcers, 3. The number of men examined was 70, and of women 30. Men suffering from gastric ulcer numbered 6; from pyloric ulcer, 21; duodenal ulcer, 33; carcinoma, 18; whereas the corresponding figures for women were: gastric ulcer, 8; pyloric ulcer, 9; duodenal ulcer, nil; carcinoma, 2.

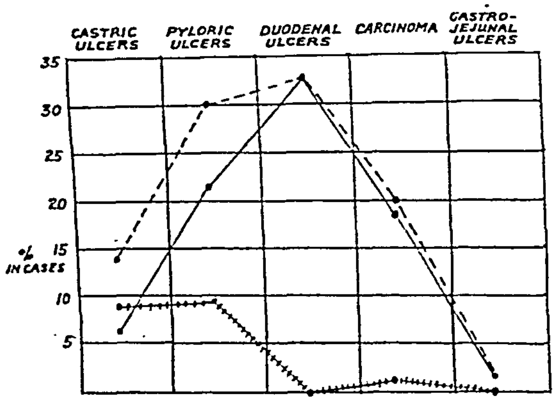
Fig. 3 represents the average curve as given by Ryle and Bennett (80 per cent. of normal cases) for comparison with the curves which are shown later corresponding to their respective groups before and after gastro-jejunostomy.

Group 1.—Gastric Ulcers.

An investigation into 14 cases shows that on an average this type of case presents before operation a fractional test-meal curve which resembles very much the normal. The resting juice has usually about 20 per cent. HCl (N/10 NaOH) total acidity, with little or no free HCl. The rise of acidity to a maximum takes about 2–2¼ hours, and then the acidity gradually falls. The rate of emptying of the stomach varies between 2¼ hours to 3 hours (the indication being the absence of both starch and sugar).

FIG. 2.



Curves showing corresponding percentages between men and women for the different lesions.

...... % occurr. of cases.
+ + + % occurr. in women.
——— % occurr. in men.

After gastro-jejunostomy has been performed it is to be noticed that the resting juice is on the average lower in total acidity than before operation. The total acidity reaches a maximum in about 1½–1¾ hours, and then rapidly falls. Note also that the total acidity does not reach such a high level as before operation, although this at no time reaches a hyperchlorhydria. A very important observation is that after operation there exists in 80 per cent. of cases an achlorhydria, and that the remaining 20 per cent. of cases have a marked hypochlorhydria. In all cases the stomach emptied rapidly, the average time interval being ¾ hour to 1½ hours (normal. 2¼ hours). In all cases after operation bile was present in the stomach at some time during the meal.

The X ray appearances of this group of cases are interesting. In most cases an ulcer was discovered, which filled with the bismuth meal. Most cases before operation showed that the stomach had a tendency to ptosis, was hypotonic, and that the motility was poor. After operation in 85 per cent. of cases the meal was seen to be leaving by the stoma, and in the remaining 15 per-cent. via the stoma and pylorus. In all cases the stomach was seen to be emptying rapidly.

In two cases of gastric ulcer excision of the ulcer together with a gastro-jejunostomy was performed. The after operation investigation of these cases shows that they fall into line with the above almost identically, both as regards the fractional test-meal and the X ray results. As a side issue, in two cases of gastric ulcer the stomach was opened and the ulcer cauterised. In one case a gastro-jejunostomy was also performed. Both cases agreed with the above results in the main. There was, however, to be noticed the following differences when no gastro-jejunostomy was performed: (1) the stomach did not empty as quickly as in the other cases; and (2) bile was not present at any time during the meal. In 80 per cent. of cases examined the pain had been completely relieved, and the patients had put on weight. Fæces were only examined in three cases after operation, and of these two showed no blood spectrum (? healed ulcer).

Figs. 4 and 5 show the average before and after operation results of gastric ulcers when treated by (1) gastro-jejunostomy alone; or (2) excision of the ulcer together with gastro-jejunostomy.

Group 2.—Pyloric Ulcers.

This group can be subdivided into (1) those ulcers occurring without stenosis and (2) those with stenosis. Altogether 30 cases of pyloric ulcer were investigated, of which 20 cases were placed in Group 1, and the remainder into Group 2. Of these, 21 cases occurred in men and nine in women. The percentage occurrence of pyloric ulcer is 30 per cent. in my series, of which 69 per cent. were in men and 31 per cent. in women.

(1) *Cases without Stenosis.*—On the average the test-meal showed that before operation patients had a resting juice which was slightly above normal, and after the introduction of the meal there was the usual fall of acidity in the first 15 minutes. After this period the free acid and total acidity steadily rose to a hyperchlorhydria, reaching a maximum in 1½–2¼ hours. The stomach showed a tendency to empty rather quicker than usual, the average time being two hours. After operation the resting juice was found to be slightly lower than before operation in acidity, but after the introduction of the meal the acidity rose to about the same level as before operation—i.e., a hyperchlorhydria was present. Bile was present in all samples withdrawn throughout the meal, and the stomach, as shown by the absence of starch or sugar, emptied more rapidly than before operation. X ray examination, in this type of case, showed the presence of an ulcer in the pylorus with a hypotonicity in a high percentage of cases, peristalsis was frequent, and motility was good. After operation the opaque meal was seen to be leaving by the stoma, and the stomach emptied rapidly.

(2) *Cases with Stenosis due to Ulcer.*—In these cases the fractional test-meal showed much the same type of curve as in section 1 of this group. There was the same slow rise of acid to a hyperchlorhydria. In this group starch and sugar could always be detected up to a period of 2¾ hours or more—thus showing the delay of emptying of the stomach. The stenosis caused by ulcer is shown by the hyperchlorhydria which is present (cf., later, pyloric stenosis due to carcinoma). After operation the meal showed that, as in section 1, the hyperchlorhydria still persisted, but was reached in quicker time than before operation. Bile was present throughout the meal and the stomach emptied rapidly. X ray appearances in these cases showed the degree of pyloric stenosis and the condition of the stomach proximal to the lesion. In a few cases some of the meal could be seen passing through an irregular pylorus as a streak; if the stenosis was complete then no meal was observed passing through it. Depending on the degree of stenosis present the X rays showed that the stomach was dilated in all cases, and was lower than usual in the erect posture. If the stenosis was not complete and not of long standing, the stomach was seen to be contracting violently, and the peristaltic waves were more frequent and vigorous than usual in their attempt to overcome the partial obstruction. In cases of pyloric stenosis of long period the stomach, in addition to being dilated, was hypotonic, and the peristaltic waves, if present at all, were of small amplitude and very infrequent. About a year after the operation the stomach was found not nearly so dilated, although always appearing a little large. Peristalsis

was normal, but hypotonus still existed. In all cases the meal was seen to be passing through the stoma and none via the pylorus, which still showed the deformity previously noticed (Figs. 6 and 7).

Group 3.—Duodenal Ulcers.

Of the 100 cases which have been examined 33 cases at operation were duodenal. All of these occurred in men. The fractional test-meal in these cases showed that all duodenal ulcers have a highly acid-resting juice—a marked hyperchlorhydria. In a number of the cases bile was found in varying quantities in the resting juice. After giving the meal the first sample withdrawn after 15 minutes always showed a large fall in the total acidity, which in some cases persisted up to half an hour. By one hour the acid level was always very high again, and this high level persisted throughout the remaining samples (hypersecretion). In all cases there was a rapid emptying of the stomach, as shown by the starch and sugar indicator—the stomach being free from these substances in 1¼–2 hours (the latter only occurring rarely). After operation the fractional test-meal showed that the resting juice still remained at the same high level of total acidity as before operation, but the free hydrochloric acid was reduced slightly, although marked hyperchlorhydria was still present. After the administration of the meal, in the first sample withdrawn there was the same fall of both total acidity and free hydrochloric acid. These rapidly rose to a hyperchlorhydria value about the same as before operation.

The time required to reach this value was from three-quarters of an hour to one hour, and it is to be noticed that this practically corresponds to the time interval before operation. There is the same tendency to hypersecretion both before and after operation, and the stomach empties in about the same time as before the operation. In some few cases this was a trifle quicker. Bile was present throughout the meal. The X ray appearances showed the presence of a duodenal ulcer in most cases. The stomach was found to be very hypertonic and peristaltic waves were rapidly following on one another in a few cases, but with the majority the stomach was hypotonic, peristalsis being fair and the motility indifferent. The stomach emptied rapidly. After operation the meal was seen leaving via the stoma, and very rapidly.

In cases of duodenal ulcer, when an excision of the ulcer was carried out together with a gastro-jejunostomy (in some cases also an appendicectomy) the type of curve after operation followed the same general rule mentioned above. The X ray appearances also conformed (Figs. 8 and 9).

Group 4.—Carcinoma of the Stomach.

These cases can be grouped into two: (1) where gastro-jejunostomy only has been performed, and (2) cases in which a partial excision of the stomach was carried out together with a gastro-jejunostomy. Twenty cases of carcinoma ventriculi were investigated, of which 18 cases occurred in men and two in women. Six cases only have been examined in which it was suspected that a carcinoma had followed on an ulcer of the pylorus. These cases fall into the general grouping of carcinoma ventriculi as regards investigation results.

(1) *Carcinoma with Gastro-jejunostomy Only.*—This group includes those cases where an irremovable growth was found with or without a pyloric stenosis. (All cases examined were growths of the pylorus, some of which had invaded the body of the stomach.) Fractional test-meals carried out on the same lines as before showed in most cases a low total acidity and low free acid in the resting juice. The free acid was always low throughout the meal, and in some cases a complete achylia was present. The total acidity rarely reached a high level, and in the great majority of cases rarely got above 30 per cent. HCl (N/10NaOH). Blood was found in all cases except one—in some cases visible, in others a positive guaiac test only was obtainable. The stomach showed delayed emptying, even though no marked pyloric stenosis could be shown by X ray examination (cf. leather-bottle stomach, when emptying of the stomach is rapid). In cases of pyloric stenosis there was marked delay in emptying of the stomach—in two cases the stomach not being free from starch or sugar after three hours, when the Einhorn tube was withdrawn. After operation it was found that there was complete achylia both in the resting juice and throughout the whole meal. The total acidity was low also. Bile was present throughout the whole meal and the stomach was emptying fairly rapidly (1½–2 hours). X ray examination before operation showed in most cases an appearance suggestive of carcinoma with varying degrees of pyloric stenosis. The stomach in some cases was dilated, and in most cases hypotonic. Peristalsis was present, but not at the site of the growth. Motility was fair. Peristalsis was only vigorous in one case examined—a case of partial pyloric stenosis. After operation the whole meal was observed to be leaving by the stoma, and the stomach had not recovered its tone or normal size, nor had it contracted down to a size at all approaching that in the case of stomachs with pyloric stenosis due to ulcer. Blood was still demonstrable.

(2) *Carcinoma with Partial Gastrectomy and Gastro-jejunostomy.*—In this group partial gastrectomy was performed, together with a gastro-jejunostomy. It should be noted that the type of anastomosis made no appreciable difference to the type of curve after operation—whether the operation be a partial gastrectomy with a posterior no-loop gastro-jejunostomy, or a Polya-Mayo operation where the jejunum is joined to the stomach some 15 inches from the duodeno-jejunal junction. (N.B.—In the Polya-Mayo operation the stomach empties at once.) The fractional test-meal before operation, with the X ray appearances correspond much as in pyloric ulcers with stenosis. After operation bile is present in the stomach throughout the meal. There exists a complete achylia with a very low total acidity. No blood was demonstrable. The stomach emptied very much quicker than in the cases in Group 1. Rarely was starch or sugar to be found after a quarter of an hour; in one case it persisted till half an hour. The X ray appearances showed that the stomach was small, and that the meal was leaving via the anastomosis rapidly and well (Figs. 10, 11, 12, and 13).

Gastro-jejunal and Jejunal Ulcers.

Three cases have been examined, but only in one case was a complete series of curves obtainable.

CASE 1.—Patient was admitted for a duodenal ulcer which was confirmed at operation. Before operation he gave a typical test-meal curve. Six months after operation, which had apparently relieved his condition, he was readmitted for symptoms almost identical with those for which he had been previously admitted. Test-meal curve showed a curve resembling a duodenal ulcer type. At a second operation a gastro-jejunal ulcer was found which was excised. Six months after the second operation his fractional test-meal curve still fitted into the duodenal group.

CASES 2 and 3 were only examined before their second operation was performed and six months after this operation. The operations originally were for duodenal ulcers, and a posterior gastro-jejunostomy had been performed. Both cases at both examinations showed curves which fitted into the duodenal group.

Two other cases are of interest for comparison:—

A case of duodenal ulcer, which had been definitely diagnosed by X ray and fractional test-meal, was treated medicinally for a considerable period—the patient eventually becoming relieved of his symptoms. Twelve months after the relief of symptoms he was admitted for perforation of his duodenal ulcer, which was confirmed and was sewn up. Six months after his operation a test-meal was carried out, and the curve presented corresponded, with remarkable accuracy, to his curve obtained when he had been in hospital previously for duodenal ulcer and treated medicinally. (Some have stated that after perforation an ulcer heals.)

A case of duodenal ulcer (not examined previously) was admitted for perforation. The ulcer was sewn over and a

was normal, but hypotonus still existed. In all cases the meal was seen to be passing through the stoma and none via the pylorus, which still showed the deformity previously noticed (Figs. 6 and 7).

Group 3.—Duodenal Ulcers.

Of the 100 cases which have been examined 33 cases at operation were duodenal. All of these occurred in men. The fractional test-meal in these cases showed that all duodenal ulcers have a highly acid-resting juice—a marked hyperchlorhydria. In a number of the cases bile was found in varying quantities in the resting juice. After giving the meal the first sample withdrawn after 15 minutes always showed a large fall in the total acidity, which in some cases persisted up to half an hour. By one hour the acid level was always very high again, and this high level persisted throughout the remaining samples (hypersecretion). In all cases there was a rapid emptying of the stomach, as shown by the starch and sugar indicator—the stomach being free from these substances in 1¼–2 hours (the latter only occurring rarely). After operation the fractional test-meal showed that the resting juice still remained at the same high level of total acidity as before operation, but the free hydrochloric acid was reduced slightly, although marked hyperchlorhydria was still present. After the administration of the meal, in the first sample withdrawn there was the same fall of both total acidity and free hydrochloric acid. These rapidly rose to a hyperchlorhydria value about the same as before operation.

The time required to reach this value was from three-quarters of an hour to one hour, and it is to be noticed that this practically corresponds to the time interval before operation. There is the same tendency to hypersecretion both before and after operation, and the stomach empties in about the same time as before the operation. In some few cases this was a trifle quicker. Bile was present throughout the meal. The X ray appearances showed the presence of a duodenal ulcer in most cases. The stomach was found to be very hypertonic and peristaltic waves were rapidly following on one another in a few cases, but with the majority the stomach was hypotonic, peristalsis being fair and the motility indifferent. The stomach emptied rapidly. After operation the meal was seen leaving via the stoma, and very rapidly.

In cases of duodenal ulcer, when an excision of the ulcer was carried out together with a gastro-jejunostomy (in some cases also an appendicectomy) the type of curve after operation followed the same general rule mentioned above. The X ray appearances also conformed (Figs. 8 and 9).

Group 4.—Carcinoma of the Stomach.

These cases can be grouped into two: (1) where gastro-jejunostomy only has been performed, and (2) cases in which a partial excision of the stomach was carried out together with a gastro-jejunostomy. Twenty cases of carcinoma ventriculi were investigated, of which 18 cases occurred in men and two in women. Six cases only have been examined in which it was suspected that a carcinoma had followed on an ulcer of the pylorus. These cases fall into the general grouping of carcinoma ventriculi as regards investigation results.

(1) *Carcinoma with Gastro-jejunostomy Only.*—This group includes those cases where an irremovable growth was found with or without a pyloric stenosis. (All cases examined were growths of the pylorus, some of which had invaded the body of the stomach.) Fractional test-meals carried out on the same lines as before showed in most cases a low total acidity and low free acid in the resting juice. The free acid was always low throughout the meal, and in some cases a complete achylia was present. The total acidity rarely reached a high level, and in the great majority of cases rarely got above 30 per cent. HCl (N/10NaOH). Blood was found in all cases except one—in some cases visible, in others a positive guaiac test only was obtainable. The stomach showed delayed emptying, even though no marked pyloric stenosis could be shown by X ray examination (cf. leather-bottle stomach, when emptying of the stomach is rapid). In cases of pyloric stenosis there was marked delay in emptying of the stomach—in two cases the stomach not being free from starch or sugar after three hours, when the Einhorn tube was withdrawn. After operation it was found that there was complete achylia both in the resting juice and throughout the whole meal. The total acidity was low also. Bile was present throughout the whole meal and the stomach was emptying fairly rapidly (1¼–2 hours). X ray examination before operation showed in most cases an appearance suggestive of carcinoma with varying degrees of pyloric stenosis. The stomach in some cases was dilated, and in most cases hypotonic. Peristalsis was present, but not at the site of the growth. Motility was fair. Peristalsis was only vigorous in one case examined—a case of partial pyloric stenosis. After operation the whole meal was observed to be leaving by the stoma, and the stomach had not recovered its tone or normal size, nor had it contracted down to a size at all approaching that in the case of stomachs with pyloric stenosis due to ulcer. Blood was still demonstrable.

(2) *Carcinoma with Partial Gastrectomy and Gastro-jejunostomy.*—In this group partial gastrectomy was performed, together with a gastro-jejunostomy. It should be noted that the type of anastomosis made no appreciable difference to the type of curve after operation—whether the operation be a partial gastrectomy with a posterior no-loop gastro-jejunostomy, or a Polya-Mayo operation where the jejunum is joined to the stomach some 15 inches from the duodeno-jejunal junction. (N.B.—In the Polya-Mayo operation the stomach empties at once.) The fractional test-meal before operation, with the X ray appearances correspond much as in pyloric ulcers with stenosis. After operation bile is present in the stomach throughout the meal. There exists a complete achylia with a very low total acidity. No blood was demonstrable. The stomach emptied very much quicker than in the cases in Group 1. Rarely was starch or sugar to be found after a quarter of an hour; in one case it persisted till half an hour. The X ray appearances showed that the stomach was small, and that the meal was leaving via the anastomosis rapidly and well (Figs. 10, 11, 12, and 13).

Gastro-jejunal and Jejunal Ulcers.

Three cases have been examined, but only in one case was a complete series of curves obtainable.

CASE 1.—Patient was admitted for a duodenal ulcer which was confirmed at operation. Before operation he gave a typical test-meal curve. Six months after operation, which had apparently relieved his condition, he was readmitted for symptoms almost identical with those for which he had been previously admitted. Test-meal curve showed a curve resembling a duodenal ulcer type. At a second operation a gastro-jejunal ulcer was found which was excised. Six months after the second operation his fractional test-meal curve still fitted into the duodenal group.

CASES 2 and 3 were only examined before their second operation was performed and six months after this operation. The operations originally were for duodenal ulcers, and a posterior gastro-jejunostomy had been performed. Both cases at both examinations showed curves which fitted into the duodenal group.

Two other cases are of interest for comparison:—

A case of duodenal ulcer, which had been definitely diagnosed by X ray and fractional test-meal, was treated medicinally for a considerable period—the patient eventually becoming relieved of his symptoms. Twelve months after the relief of symptoms he was admitted for perforation of his duodenal ulcer, which was confirmed and was sewn up. Six months after his operation a test-meal was carried out, and the curve presented corresponded, with remarkable accuracy, to his curve obtained when he had been in hospital previously for duodenal ulcer and treated medicinally. (Some have stated that after perforation an ulcer heals.)

A case of duodenal ulcer (not examined previously) was admitted for perforation. The ulcer was sewn over and a

posterior gastro-jejunostomy was performed. Six months after operation a curve was obtained typical of the duodenal series obtainable after operation.

Fractional Test-Meal Results.

Group 1: Gastric Ulcers.—This group gives an almost normal fractional test-meal curve before operation, and X ray shows that there is a tendency to hypotonus. After gastro-jejunostomy the free hydrochloric acid is markedly diminished (hypochlorhydria or achlorhydria); the total acidity is also diminished. The stomach empties rapidly after operation and bile is present. This result holds good whether the ulcer is excised or cauterised if a gastro-jejunostomy is performed.

Group 2: Pyloric Ulcers.—In this group there is a resting juice which is higher than normal and a steady rise of acidity to a hyperchlorhydria, which is reached in about two and a quarter hours (average). Before operation there is a hypotonicity of the stomach. After operation the resting juice was reduced slightly, but later the acidity reached almost the same level as before operation. Bile was present, and the stomach emptied more rapidly than before. Pyloric ulcers with stenosis agree with the above both before and after operation, except that before operation there is delay in the emptying of the stomach. After operation the stomach shows a tendency to recover its normal size and tone.

Group 3: Duodenal Ulcers.—These cases show a highly acid resting juice, which rapidly falls after giving the meal but as quickly rises to a hyperchlorhydria with a hypersecretion. The stomach is either hypertonic or hypotonic, and empties rapidly. After operation, whether only gastro-jejunostomy has been performed or has been combined with excision of the ulcer, a highly acid resting juice persists which, after falling on administration of the meal, rapidly rises to a hyperchlorhydria. The stomach empties rapidly and bile is present.

Gastro-jejunal and jejunal ulcers, if following on operations for duodenal ulcers, fall into this group as regards the results obtained before and after operation.

Group 4: Carcinoma of the Stomach.—These cases show low total acidity throughout the meal, and in most cases an achlorhydria. There may be a higher acidity (resembling that obtained in pyloric ulcers) present if the carcinoma is following on an ulcer. Blood is usually present, and there is delay in the emptying of the stomach (whether stenosis be present or not, except in cases of "leather-bottle" stomach). Regardless of the type of operation—excision or gastro-jejunostomy—a hypochlorhydria or achylia exists after operation. The stomach empties rapidly and bile is present—particularly in cases of gastrectomy.

This summary of results bears out what was anticipated by me on the results of a few cases published some time ago.[6]

X Ray Results.

Group 1: Gastric Ulcers.—Stomachs in this group are usually hypotonic, the peristalsis is fair, and the motility usually fairly good. After operation the meal passes out of the stomach usually via the stoma. The stomach still remains hypotonic with a fair peristaltic action.

Group 2: Pyloric Ulcers.—(1) Without stenosis: Most of these cases show hypotonic stomachs, the peristalsis is fair and the motility good. After operation the observations are as before operation, except that the meal is seen leaving via the stoma. (2) With stenosis: In these cases the stomach is hypotonic with a poor motility. The stomach is dilated and peristalsis, if the case be early, is exaggerated, but, if late, there may be no peristalsis at all, or else the peristaltic waves are irregular and of small amplitude. After operation the meal leaves via the stoma, and some dilatation still persists. The motility is still poor, and peristaltic waves are fairly frequent but of small size.

Group 3: Duodenal Ulcers.—In these cases the stomach is more often hypotonic than hypertonic. The peristaltic waves are frequent and the motility in some cases was good, in others bad. After operation the meal was leaving via the stoma, but the observations were otherwise the same as before operation.

Carcinoma Ventriculi.—(1) Cases without stenosis: Peristalsis was observable on both sides of the growth but was absent at the site of the growth. The stomach was hypotonic but the motility was good. After operation the same observations held good, except that the meal was now leaving via the stoma. (2) Cases with stenosis: This group corresponds very much with stenosis due to pyloric ulcers. The stomach is hypotonic with a poor motility. It is dilated and no peristalsis is usually seen. If waves be present they are of very small size and occur proximal to the growth. After operation the meal leaves via the stoma. In cases in which a resection of the stomach had been carried out (e.g., Polya-Mayo operation) the after X ray results showed the meal to be passing at once into the jejunum, and the stomach to be of very small size.

Conclusions.

(1) In most cases of pathological lesions of the stomach, whether ulcer or carcinoma, the stomach has a tendency to hypotonicity. The peristaltic waves do not vary in size or frequency, except in cases of pyloric stenosis, when the waves may be exaggerated if the case be early, or there may be complete absence of waves if the stenosis be almost complete. In all these cases of stenosis the motility is poor, and no waves are to be seen in the neighbourhood of the ulcer or growth. Gastro-jejunostomy allows a certain degree of recovery of the stomach to occur as regards size in cases of stenosis due to ulcer, but there is never so much recovery in cases due to carcinoma. Peristalsis remains as before.

(2) Test-meal curves show that four types of curve are usually obtainable: (*a*) Gastric ulcers tend to give a curve resembling the normal; (*b*) pyloric ulcers a curve rising to a hyperchlorhydria after a period of about two hours (in some few cases this type of curve was not obtained but a curve rather of the hypochlorhydria variety); (*c*) duodenal ulcers a curve with a highly acid resting juice and a rapidly rising hypersecretory curve; (*d*) carcinoma of the stomach a curve with a low acidity is usually present, and in some cases a complete achylia. The time of emptying of the stomach in each group agrees with X ray findings; in gastric ulcers the stomach empties in normal time, pyloric ulcers without stenosis empty slightly quicker than normally, pyloric stenosis causes delay in emptying, and in carcinoma there is usually a slightly delayed emptying.

(3) Gastro-jejunostomy, as proved both by X rays and test-meal, allows the stomach to empty more quickly than usual (except in some few cases of duodenal ulcer). The meal leaves via the stoma and in only a very few cases via the pylorus as well. Particularly is the rate of emptying increased in cases of pyloric stenosis whether due to ulcer or growth, and this is very marked in cases of partial gastrectomy with gastro-jejunostomy, where the meal passes at once into the jejunum.

(4) Gastro-jejunostomy in cases of gastric ulcer causes a reduction in the free hydrochloric acid value, but the total acidity remains much as before.

(5) Gastro-jejunostomy in cases of pyloric ulcer does not alter to any material extent the curve—a hyperchlorhydria still exists.

(6) A highly acid resting juice with a hyperchlorhydria and hypersecretion still exists in duodenal ulcer curves after gastro-jejunostomy.

(7) Carcinomata have a low free and total acidity after gastro-jejunostomy, and in cases of partial gastrectomy an achylia is found.

---

[6] Bonar: THE LANCET, 1921, ii., 955.

(8) Gastro-jejunal or jejunal ulcers, if occurring after a gastro-jejunostomy for duodenal ulcer, still retain the characteristic curve of their original group—i.e., duodenal ulcer.

(9) In all cases bile gets back into the stomach during some part of or during all the test-meal.

(10) The maximum amount of upset to gastric secretion occurs in lesions in the pylorus or duodenum, ulcers giving high acidities, growths low acidities.

(11) In cases of ulcers with high acidities gastro-jejunostomy does not cause to any extent a reduction of the acidity. Its operative value therefore must be merely mechanical, constituting an attempt to rest the ulcer by short-circuiting food through the stoma. This therefore strongly points to medicinal treatment being persisted in for pyloric ulcers (where no stenosis exists) and duodenal ulcers. Pyloric stenosis is a positive indication for gastro-jejunostomy—i.e., a mechanical means of outlet for the meal must be provided. In cases of stenosis due to ulcer the acidity value is not materially altered after gastro-jejunostomy.

(12) In cases of carcinoma of the stomach gastro-jejunostomy works in much the same way as in gastric and pyloric ulcers, depending on whether a gastrectomy has been carried out at the same time or not. If a gastrectomy has been performed as well as the gastro-jejunostomy *no* free hydrochloric acid is present (cf. gastric ulcers), but in this case the total acidity is reduced as well (cf. gastric ulcers where the total acidity almost reaches the same level as before operation). In cases where only a gastro-jejunostomy has been performed the free hydrochloric acid is reduced almost to an achylia, but the total acidity may only be reduced to a small extent (particularly in cases of growth following on ulcer).

(13) Hurst[7] states "that the predisposing cause of a duodenal ulcer is a hypertonic stomach with excessive acid secretion, and whatever operation is done the patient still has the same hypertonic stomach." From these results it appears that a hypersecretion does exist in duodenal ulcers, but not necessarily a hypertonic stomach, for in the majority of my cases a hypotonic stomach was found by X rays.

(14) Gastric function is permanently upset in cases of growths of the stomach.

(15) Gastric function is permanently upset in cases of ulcers unless they heal.

(16) Gastro-jejunostomy is only indicated in cases of pyloric stenosis to act mechanically in providing an outlet for food. It relieves the pain caused by ulcer, but does not reduce acidity by allowing the entrance of bile into the stomach in cases of high acid-producing ulcers.

(17) There is a tendency for the formation of gastro-jejunal or jejunal ulcers (three cases out of 100 *in my series*) after gastro-jejunostomy in cases with high acidity.

(18) That medical treatment will be required in all cases when a gastro-jejunostomy has been performed in an attempt to reduce high acidity and to prevent gastro-jejunal ulcers.

(19) That only pyloric and duodenal ulcers cause spasm of the pylorus and therefore a resultant hypersecretion—sufficient bile never getting into the stomach to reduce the acidity to any material extent. Gastric ulcers do not cause a pyloro-spasm and therefore there is no hypersecretion. Carcinomata, by their infiltration, prevent pyloro-spasm, and therefore a low acidity is to be anticipated.

(20) Gastro-jejunostomy in pyloric and duodenal ulcers apparently does not cause a release from the pyloro-spasm, and even though bile enters the stomach in greater quantities than before operation it is not sufficient to cause a reduction in the acidity to a marked extent. In cases of carcinoma one would anticipate that more bile entering the stomach would cause a reduction in the acidity, and this is proved by the results before mentioned.

CHANGES IN THE POLARITY OF THE FŒTUS

DURING THE LATER WEEKS OF PREGNANCY.

BY A. LOUISE McILROY, M.D., D.Sc. GLASG.,

AND

DOROTHY LEVERKUS, M.B., B.S. LOND.

(From the Obstetrical and Gynæcological Unit of the Royal Free Hospital, London School of Medicine for Women.)

OWING to antenatal work the subject of pelvic presentations has assumed fresh importance. The object of the present research is to investigate the frequency of the occurrence of spontaneous version of the fœtus in the uterus, and its influence upon the prognosis and treatment of obstetrical cases. Very little information has been hitherto available in the literature. To those engaged in antenatal research it is obvious that pelvic presentations occur much more frequently during the later weeks of pregnancy than has been generally supposed.

In the Obstetrical Unit pelvic presentations occurred in 1·74 per cent. of all labours of the patients who had been under observation in the antenatal clinic and in the wards. These include cases where podalic version was performed during pregnancy and at the onset of labour. Attention has also been drawn to the facility with which the fœtus tends to right itself in the majority of cases to a head presentation. It is difficult to arrive at any definite conclusion as to the cause of spontaneous version and the persistence of pelvic presentations. The fœtus, with very few exceptions, accommodates its long axis to the vertical axis of the uterus, therefore we are mainly concerned with changes from cephalic to pelvic presentations and vice versa. As the fœtus has relatively much more power of movement in the earlier weeks of pregnancy, when its position cannot be ascertained with accuracy, the present investigation is confined to the later weeks of pregnancy, more especially from the twenty-eighth week onwards.

The normal attitude of the fœtus is one of flexion which enables it to occupy the smallest space possible. The pressure from the uterus, as the fœtus grows in size, tends to maintain it in the bipolar position and in an attitude of flexion. As a head presentation is much more frequent than a pelvic presentation there must be some reason for this fact, and various theories as to its ætiology are current.

Theories as to Relative Frequency of Head Presentations.

1. *The Relationship of the Shape of the Uterus to the Fœtus in its Position of Flexion.*—The uterus in its normal pregnant condition is broader at the fundus than at the lower segment. The nearly full-time fœtus is broader at its pelvic than at its cephalic pole. Therefore the most usual position is for the pelvic pole to occupy the fundus, giving the normal cephalic presentation. The uterine walls, as pregnancy advances, tend to maintain this position by their uniform pressure upon the fœtus, or to rotate the fœtus by their contractions into the most adaptable position possible, and if either factor in this relationship be abnormal a pelvic presentation may result. This is shown by the occurrence of pelvic presentations in cases of hydrocephalus, fœtal goitre, and pre-maturity where the head is out of proportion to the body, or where changes in the shape of the uterus have occurred as the result of pathological complications.

2. *Gravity* (Matthews Duncan) is said to be a factor in maintaining the head presentation, the centre of gravity of the fœtus being in the region of the shoulders.

3. *Activity on the part of the fœtus* itself which enables it to kick itself out of the region of the pelvis and to rotate so that the head should occupy the lower zone of the uterine cavity. If the pelvic pole of the fœtus is in the fundus the fœtus has no bony resistance to kick against, and therefore it is more difficult to bring about a rotation.

Explanation of Causation and Persistence of Pelvic Presentations.

Many other theories are given for the causation and persistence of pelvic presentations, but as they posterior gastro-jejunostomy was performed. Six months after operation a curve was obtained typical of the duodenal series obtainable after operation.

Fractional Test-Meal Results.

Group 1: Gastric Ulcers.—This group gives an almost normal fractional test-meal curve before operation, and X ray shows that there is a tendency to hypotonus. After gastro-jejunostomy the free hydrochloric acid is markedly diminished (hypochlorhydria or achlorhydria); the total acidity is also diminished. The stomach empties rapidly after operation and bile is present. This result holds good whether the ulcer is excised or cauterised if a gastro-jejunostomy is performed.

Group 2: Pyloric Ulcers.—In this group there is a resting juice which is higher than normal and a steady rise of acidity to a hyperchlorhydria, which is reached in about two and a quarter hours (average). Before operation there is a hypotonicity of the stomach. After operation the resting juice was reduced slightly, but later the acidity reached almost the same level as before operation. Bile was present, and the stomach emptied more rapidly than before. Pyloric ulcers with stenosis agree with the above both before and after operation, except that before operation there is delay in the emptying of the stomach. After operation the stomach shows a tendency to recover its normal size and tone.

Group 3: Duodenal Ulcers.—These cases show a highly acid resting juice, which rapidly falls after giving the meal but as quickly rises to a hyperchlorhydria with a hypersecretion. The stomach is either hypertonic or hypotonic, and empties rapidly. After operation, whether only gastro-jejunostomy has been performed or has been combined with excision of the ulcer, a highly acid resting juice persists which, after falling on administration of the meal, rapidly rises to a hyperchlorhydria. The stomach empties rapidly and bile is present.

Gastro-jejunal and jejunal ulcers, if following on operations for duodenal ulcers, fall into this group as regards the results obtained before and after operation.

Group 4: Carcinoma of the Stomach.—These cases show low total acidity throughout the meal, and in most cases an achlorhydria. There may be a higher acidity (resembling that obtained in pyloric ulcers) present if the carcinoma is following on an ulcer. Blood is usually present, and there is delay in the emptying of the stomach (whether stenosis be present or not, except in cases of "leather-bottle" stomach). Regardless of the type of operation—excision or gastro-jejunostomy—a hypochlorhydria or achylia exists after operation. The stomach empties rapidly and bile is present—particularly in cases of gastrectomy.

This summary of results bears out what was anticipated by me on the results of a few cases published some time ago.[6]

X Ray Results.

Group 1: Gastric Ulcers.—Stomachs in this group are usually hypotonic, the peristalsis is fair, and the motility usually fairly good. After operation the meal passes out of the stomach usually via the stoma. The stomach still remains hypotonic with a fair peristaltic action.

Group 2: Pyloric Ulcers.—(1) Without stenosis: Most of these cases show hypotonic stomachs, the peristalsis is fair and the motility good. After operation the observations are as before operation, except that the meal is seen leaving via the stoma. (2) With stenosis: In these cases the stomach is hypotonic with a poor motility. The stomach is dilated and peristalsis, if the case be early, is exaggerated, but, if late, there may be no peristalsis at all, or else the peristaltic waves are irregular and of small amplitude. After operation the meal leaves via the stoma, and some dilatation still persists. The motility is still poor, and peristaltic waves are fairly frequent but of small size.

Group 3: Duodenal Ulcers.—In these cases the stomach is more often hypotonic than hypertonic. The peristaltic waves are frequent and the motility in some cases was good, in others bad. After operation the meal was leaving via the stoma, but the observations were otherwise the same as before operation.

Carcinoma Ventriculi.—(1) Cases without stenosis: Peristalsis was observable on both sides of the growth but was absent at the site of the growth. The stomach was hypotonic but the motility was good. After operation the same observations held good, except that the meal was now leaving via the stoma. (2) Cases with stenosis: This group corresponds very much with stenosis due to pyloric ulcers. The stomach is hypotonic with a poor motility. It is dilated and no peristalsis is usually seen. If waves be present they are of very small size and occur proximal to the growth. After operation the meal leaves via the stoma. In cases in which a resection of the stomach had been carried out (e.g., Polya-Mayo operation) the after X ray results showed the meal to be passing at once into the jejunum, and the stomach to be of very small size.

Conclusions.

(1) In most cases of pathological lesions of the stomach, whether ulcer or carcinoma, the stomach has a tendency to hypotonicity. The peristaltic waves do not vary in size or frequency, except in cases of pyloric stenosis, when the waves may be exaggerated if the case be early, or there may be complete absence of waves if the stenosis be almost complete. In all these cases of stenosis the motility is poor, and no waves are to be seen in the neighbourhood of the ulcer or growth. Gastro-jejunostomy allows a certain degree of recovery of the stomach to occur as regards size in cases of stenosis due to ulcer, but there is never so much recovery in cases due to carcinoma. Peristalsis remains as before.

(2) Test-meal curves show that four types of curve are usually obtainable: (*a*) Gastric ulcers tend to give a curve resembling the normal; (*b*) pyloric ulcers a curve rising to a hyperchlorhydria after a period of about two hours (in some few cases this type of curve was not obtained but a curve rather of the hypochlorhydria variety); (*c*) duodenal ulcers a curve with a highly acid resting juice and a rapidly rising hypersecretory curve; (*d*) carcinoma of the stomach a curve with a low acidity is usually present, and in some cases a complete achylia. The time of emptying of the stomach in each group agrees with X ray findings; in gastric ulcers the stomach empties in normal time, pyloric ulcers without stenosis empty slightly quicker than normally, pyloric stenosis causes delay in emptying, and in carcinoma there is usually a slightly delayed emptying.

(3) Gastro-jejunostomy, as proved both by X rays and test-meal, allows the stomach to empty more quickly than usual (except in some few cases of duodenal ulcer). The meal leaves via the stoma and in only a very few cases via the pylorus as well. Particularly is the rate of emptying increased in cases of pyloric stenosis whether due to ulcer or growth, and this is very marked in cases of partial gastrectomy with gastro-jejunostomy, where the meal passes at once into the jejunum.

(4) Gastro-jejunostomy in cases of gastric ulcer causes a reduction in the free hydrochloric acid value, but the total acidity remains much as before.

(5) Gastro-jejunostomy in cases of pyloric ulcer does not alter to any material extent the curve—a hyperchlorhydria still exists.

(6) A highly acid resting juice with a hyperchlorhydria and hypersecretion still exists in duodenal ulcer curves after gastro-jejunostomy.

(7) Carcinomata have a low free and total acidity after gastro-jejunostomy, and in cases of partial gastrectomy an achylia is found.

---

[6] Bonar: THE LANCET, 1921, ii., 955.

(8) Gastro-jejunal or jejunal ulcers, if occurring after a gastro-jejunostomy for duodenal ulcer, still retain the characteristic curve of their original group—i.e., duodenal ulcer.

(9) In all cases bile gets back into the stomach during some part of or during all the test-meal.

(10) The maximum amount of upset to gastric secretion occurs in lesions in the pylorus or duodenum, *ulcers giving high acidities, growths low acidities.*

(11) In cases of ulcers with high acidities gastro-jejunostomy does not cause to any extent a reduction of the acidity. Its operative value therefore must be merely mechanical, constituting an attempt to rest the ulcer by short-circuiting food through the stoma. This therefore strongly points to medicinal treatment being persisted in for pyloric ulcers (where no stenosis exists) and duodenal ulcers. *Pyloric stenosis is a positive indication for gastro-jejunostomy*—i.e., a mechanical means of outlet for the meal must be provided. In cases of stenosis due to ulcer the acidity value is not materially altered after gastro-jejunostomy.

(12) In cases of carcinoma of the stomach gastro-jejunostomy works in much the same way as in gastric and pyloric ulcers, depending on whether a gastrectomy has been carried out at the same time or not. If a gastrectomy has been performed as well as the gastro-jejunostomy no free hydrochloric acid is present (cf. gastric ulcers), but in this case the total acidity is reduced as well (cf. gastric ulcers where the total acidity almost reaches the same level as before operation). In cases where only a gastro-jejunostomy has been performed the free hydrochloric acid is reduced almost to an achylia, but the total acidity may only be reduced to a small extent (particularly in cases of growth following on ulcer).

(13) Hurst[7] states "that the *predisposing cause of a duodenal ulcer is a hypertonic stomach with excessive acid secretion, and whatever operation is done the patient still has the same hypertonic stomach.*" From these results it appears that a hypersecretion does exist in duodenal ulcers, but not necessarily a hypertonic stomach, for in the majority of my cases a hypotonic stomach was found by X rays.

(14) Gastric function is permanently upset in cases of growths of the stomach.

(15) Gastric function is permanently upset in cases of ulcers unless they heal.

(16) Gastro-jejunostomy is only indicated in cases of pyloric stenosis to act mechanically in providing an outlet for food. It relieves the pain caused by ulcer, but does not reduce acidity by allowing the entrance of bile into the stomach in cases of high acid-producing ulcers.

(17) There is a tendency for the formation of gastro-jejunal or jejunal ulcers (three cases out of 100 in my series) after gastro-jejunostomy in cases with high acidity.

(18) That medical treatment will be required in all cases when a gastro-jejunostomy has been performed in an attempt to reduce high acidity and to prevent gastro-jejunal ulcers.

(19) That only pyloric and duodenal ulcers cause spasm of the pylorus and therefore a resultant hypersecretion—sufficient bile never getting into the stomach to reduce the acidity to any material extent. Gastric ulcers do not cause a pyloro-spasm and therefore there is no hypersecretion. Carcinomata, by their infiltration, prevent pyloro-spasm, and therefore a low acidity is to be anticipated.

(20) Gastro-jejunostomy in pyloric and duodenal ulcers apparently does not cause a release from the pyloro-spasm, and even though bile enters the stomach in greater quantities than before operation it is not sufficient to cause a reduction in the acidity to a marked extent. In cases of carcinoma one would anticipate that more bile entering the stomach would cause a reduction in the acidity, and this is proved by the results before mentioned.

CHANGES IN THE POLARITY OF THE FŒTUS

DURING THE LATER WEEKS OF PREGNANCY.

BY A. LOUISE McILROY, M.D., D.SC. GLASG.,

AND

DOROTHY LEVERKUS, M.B., B.S. LOND.

(From the Obstetrical and Gynæcological Unit of the Royal Free Hospital, London School of Medicine for Women.)

OWING to antenatal work the subject of pelvic presentations has assumed fresh importance. The object of the present research is to investigate the frequency of the occurrence of spontaneous version of the fœtus in the uterus, and its influence upon the prognosis and treatment of obstetrical cases. Very little information has been hitherto available in the literature. To those engaged in antenatal research it is obvious that pelvic presentations occur much more frequently during the later weeks of pregnancy than has been generally supposed.

In the Obstetrical Unit pelvic presentations occurred in 1·74 per cent. of all labours of the patients who had been under observation in the antenatal clinic and in the wards. These include cases where podalic version was performed during pregnancy and at the onset of labour. Attention has also been drawn to the facility with which the fœtus tends to right itself in the majority of cases to a head presentation. It is difficult to arrive at any definite conclusion as to the cause of spontaneous version and the persistence of pelvic presentations. The fœtus, with very few exceptions, accommodates its long axis to the vertical axis of the uterus, therefore we are mainly concerned with changes from cephalic to pelvic presentations and vice versa. As the fœtus has relatively much more power of movement in the earlier weeks of pregnancy, when its position cannot be ascertained with accuracy, the present investigation is confined to the later weeks of pregnancy, more especially from the twenty-eighth week onwards.

The normal attitude of the fœtus is one of flexion which enables it to occupy the smallest space possible. The pressure from the uterus, as the fœtus grows in size, tends to maintain it in the bipolar position and in an attitude of flexion. As a head presentation is much more frequent than a pelvic presentation there must be some reason for this fact, and various theories as to its ætiology are current.

Theories as to Relative Frequency of Head Presentations.

1. *The Relationship of the Shape of the Uterus to the Fœtus in its Position of Flexion.*—The uterus in its normal pregnant condition is broader at the fundus than at the lower segment. The nearly full-time fœtus is broader at its pelvic than at its cephalic pole. Therefore the most usual position is for the pelvic pole to occupy the fundus, giving the normal cephalic presentation. The uterine walls, as pregnancy advances, tend to maintain this position by their uniform pressure upon the fœtus, or to rotate the fœtus by their contractions into the most adaptable position possible, and *if either factor in this relationship be abnormal a pelvic presentation may result.* This is shown by the occurrence of pelvic presentations in cases of hydrocephalus, fœtal goitre, and pre-maturity where the head is out of proportion to the body, or where changes in the shape of the uterus have occurred as the result of pathological complications.

2. *Gravity* (Matthews Duncan) is said to be a factor in maintaining the head presentation, the centre of gravity of the fœtus being in the region of the shoulders.

3. *Activity on the part of the fœtus* itself which enables it to kick itself out of the region of the pelvis and to rotate so that the head should occupy the lower zone of the uterine cavity. If the pelvic pole of the fœtus is in the fundus the fœtus has no bony resistance to kick against, and therefore it is more difficult to bring about a rotation.

Explanation of Causation and Persistence of Pelvic Presentations.

Many other theories are given for the causation and persistence of pelvic presentations, but as they concern more or less the ætiology of pelvic deliveries, they cannot be adopted in many cases of pelvic presentation which occur during pregnancy, and which are more or less transient.

Of these theories the following may be mentioned:

1. *Prematurity.*—In early pregnancy the fœtal head is larger in proportion to the fœtal pelvis than when nearer term, therefore it may adapt itself more easily to the fundus. The frequency of pelvic presentations at delivery is greater in premature cases than at term (1 in 30 as compared with 1 in 62 at term, Pinard). For the purpose of the present investigation 1900 cases were taken which had been followed through the antenatal clinic and completed delivery in the wards. These cases were under the care of the unit senior staff, which included Dr. Gertrude Dearnley, Dr. Catherine Houlton, and Dr. Edith Hall.

Pelvic presentations were found during pregnancy at one time or another in 600 cases. Of these, 33 were delivered as pelvic presentations. In 18 out of these 33 the fœtus was premature. It must be taken into consideration, however, that pregnancy was interrupted or that premature labour occurred in a number of cases, owing to pathological conditions of the mother.

Of all cases investigated where the pelvic pole had presented during pregnancy 25 were delivered prematurely, of which 16 were primigravidæ and nine multiparæ. They were delivered with the head in advance, after the performance of version or the occurrence of spontaneous version.

It would seem as if prematurity were not the main or primary factor in the causation of pelvic polar presentations, but rather that labour had occurred or was induced at a stage when the fœtus was occupying an inverted position in the uterus. If nothing interferes with its continued occupation of the uterus the fœtus will, in the majority of cases, right itself some weeks before labour is due.

2. *Multiparity*, because of the roomy cavity and lax uterine walls, is said to favour the persistence of pelvic presentations. Winckel found 1 in 80 cases of primigravidæ and 1 in 23 cases of multiparæ. Of the total 600 cases investigated during pregnancy we found that 340 were primigravidæ and 147 in their second pregnancy, and the remaining numbers diminished as the number of previous pregnancies increased. In the pelvic presentation cases at delivery the primigravidæ numbered 19 and the multiparæ 14.

The statistics are open to error in the matter of multiparity, as the majority of the cases attending the clinic are primigravidæ, and the next in frequency are in their second pregnancy.

If the uterus is lax and its cavity enlarged it should tend to facilitate the effect of gravity to some extent in bringing about a head presentation. Once a head presentation is established, however, the pressure of the uterus on the fœtus may not be sufficient to keep it in position. In the pelvic deliveries, although the primigravidæ predominated in number, eight of these were premature. This fact, as already stated, complicates the investigation of possible causes.

3. *Obstruction at the pelvic inlet by tumours, placenta prævia, &c.*, may influence pelvic deliveries, but it cannot be said to affect the spontaneous version of the fœtus during pregnancy. Three cases of fibroid tumours occurred among the 600 cases, and in each instance delivery took place by the cephalic pole. Spontaneous version occurred several weeks before the onset of labour. There were 8 cases of placenta prævia (primigravidæ 3, multiparæ 5), 4 being delivered with the head presentation.

Placenta Prævia (Eight Cases).

Cephalic Pole Delivery.

Spontaneous version.	Week.	
1 case	30th	Delivery by Cæsarean section.
1 ,, ...	37th	
1 ,, ...	26th	Delivery normal.
1 ,, ...	30th	

Pelvic Pole Delivery.

Version.	Week.	
1 case was performed	38th	Delivery by Cæsarean section.
1 ,, ,, ,,	26th	Delivery as footling.
1 ,, ,, ,,	32nd	
1 ,, ,, ,,	28th	

4. The *age of the mother* had no influence upon spontaneous version. The statistics corresponded to the average reproductive age. Five primigravidæ were between 36 and 41 years. None of the others was over 33

5. The *sex of the fœtus* corresponded with the average cephalic rate and had no influence upon spontaneous version.

6. A minor degree of *pelvic contraction* was observed in a considerable number of cases, but did not seem to bear much relationship to the polar rotation of the fœtus, nor did it much influence pelvic deliveries, as out of 33 pelvic polar deliveries only two cases of pelvic contraction were observed. Every case was carefully measured at the first examination. The proportion of pelvic contraction cases was about the same as that found in those in which spontaneous version did not take place.

It is possible that pelvic contraction may favour obliquity of the uterine and fœtal axis, but further research is being carried out with regard to this.

7. *Twins.*—Eleven cases of twins were investigated but not included with the other cases. In five cases both fœtuses were born head first; in five cases one fœtus was born head first, and the other breech first, and in one case both fœtuses were born breech first. In one of these labour occurred before term. There was one case of triplets where labour was premature, two of the fœtuses were born head first, and one breech first. It would seem that for better adaptation of two fœtuses in the uterus less room is taken up when one presents by the head and the other by the breech.

8. *Hydramnios* was present in four cases of twin pregnancy, but only in four of the single pregnancy cases. It is very difficult to estimate with any degree of accuracy the amount of liquor amnii in any given case.

9. *Deformities of the fœtus* obviously tend to change its normal presentation. In one case only was hydrocephalus observed, and in one spina bifida.

10. *Other factors* were investigated with regard to their influence upon polar rotation of the fœtus, but gave no evidence of their importance. These were *length* and *weight* of the fœtus, and *length of the umbilical cord.*

Before discussing the influence of these factors, it will be well to give some account of the behaviour of the fœtus with regard to polar rotation in the later weeks of pregnancy.

Spontaneous version from the pelvic to the cephalic pole occurred in 451 cases. (Table I.)

Spontaneous version occurs most frequently between the thirtieth and thirty-sixth weeks, as a rule before the thirty-sixth week, and most frequently between the thirty-second and thirty-fourth weeks.

Version was successfully performed in 69 cases, the greatest number occurring between the thirty-second and thirty-fourth weeks. (Table II.)

TABLE II.—*Version Successfully Performed Once in Pelvic Presentations.*

Week.	Primi-gravidæ.	Multi-paræ.	Total	Week.	Primi-gravidæ.	Multi-paræ.	Total
26th	0	1	1	35th	2	2	4
28th	1	0	1	36th	5	6	11
30th	4	3	7	38th	3	3	6
32nd	8	7	15	40th	1	2	3
34th	6	15	21				

Anæsthetics were given in four of these cases. The infants were all born alive. Spontaneous rotation to a pelvic presentation occurred again in five cases, but the fœtus righted itself before onset of labour.

Attempts at version failed in 27 cases, 17 of which were primigravidæ and 10 multiparæ. Spontaneous version occurred subsequently in 13 cases. Version was again attempted and successfully performed in 8 cases. Failure was found to be due to extended legs in 6 of the cases, anæsthetics were given in 11 cases in which the legs were extended, but version was successful in only 5. Anæsthesia, therefore, is of little help in rotating the fœtus if the legs and back are extended.

Transverse Presentations.

Twenty-four cases were diagnosed as transverse, of which 8 were primigravidæ and 16 multiparæ. Spontaneous version occurred in 19 cases, in the majority between the thirtieth and thirty-fourth weeks, and in 2 cases at the onset of labour. Version was performed in 5 cases, 1 at the thirtieth week, 1 at the thirty-second week, 1 at the thirty-fourth week, and 2 at the thirty-sixth week. In one of the latter spontaneous version took place to the transverse, and spontaneous version to head presentation. All 24 cases ended in vertex deliveries except one, which was a case of hydramnios with pelvic delivery. Three cases showed a minor degree of pelvic contraction, 1 being delivered by Cæsarean section and 2 by induction of labour.

Factors Influencing Spontaneous Version Rotation.

Influence of Length of the Fœtus on Spontaneous Version Rotation.—The fœtuses were measured at birth, and the average lengths were found to correspond closely with those of other cases where the cephalic presentation remained throughout pregnancy. The average lengths were divided into four main groups which gave in order of frequency 20 inches, 21 inches, 19 inches, and 22 inches. The longest fœtus measured was 25 inches. It was found that the length of the fœtus had little or no influence upon failure to perform version.

In one case of transverse presentation version was easily performed at the thirty-sixth week, the fœtus at birth being 24 inches in length. Version failed in one case at the thirty-third week, and delivery occurred at term by the pelvic pole. The length of the fœtus was 18 inches.

In cases where failure to perform version occurred the fœtus was found in every case to be of average length at birth. In cases where version was easy or occurred spontaneously the fœtus was up to the average length or longer. In some cases in which attempts at version failed, spontaneous version occurred a few weeks later when the fœtus was longer. We therefore came to the conclusion that, contrary to our expectations, the length of the fœtus has little if any influence upon its polar rotation.

Weight of the Fœtus.—The infants born at term were of average standard weight. The most frequent weight found was 6 lb. 12 oz.; the next was 7 lb. 12 oz.; the next was 7 lb. 4 oz.; and the next was 7 lb. 8 oz.

Spontaneous version occurred in two cases at the thirty-eighth week: in the first case the weight was 10 lb. at birth, in the second the weight was 9 lb. 12 oz. at birth; one case at the thirty-second week, weight 9 lb. 6 oz. at birth. Version was performed easily in one case at the thirtieth week, weight at birth 9 lb. 8 oz. In one case version was performed at the thirty-fourth and again at the thirty-sixth week, weight 9 lb. 9 oz. These weights were well above the average and might be expected to influence version. In 12 cases in which attempts at version failed, the weight at birth was average or below average. Spontaneous version occurred later in eight of these cases and pelvic delivery in four cases.

Length of the Umbilical Cord.—A short cord has no influence upon the rotation of the fœtus or on failure to perform version. Spontaneous version occurred in 1 case of a cord 10 inches, 2 cases of 12 inches, 1 case of 13 inches, and 9 cases of 14 inches. Version was performed easily in 1 case of a cord 10 inches, 2 cases of 12 inches, 1 case of 13 inches, and 1 case of 14 inches, and 1 case of 15 inches. Spontaneous version or version was performed in all short cord cases. When version failed the cords were of normal length. In one case of a cord of 12 inches attempts at version were discontinued at the thirty-sixth week, as the patient was faint. Spontaneous version took place at the thirty-eighth week. As in cephalic presentations, long cords have a greater tendency to loop round the neck or body. The occurrence of loops in the cord was not more frequent than in the control cases.

Pelvic Polar Presentations.

Thirty-three cases were delivered as pelvic presentations. Of these, 11 were primigravidæ at term and 4 multiparæ at term. 18 were premature, of which 8 were primiparæ and 10 multiparæ. Appended are details of the cases. (Table III.)

In the cases at term the pelvic presentation was due in 7 cases to extended legs, version having failed in 3 cases, and 2 were not diagnosed before delivery. The causes of the remaining cases could not be ascertained, some were not seen more than once or twice during pregnancy, and in others the fœtus again rotated after version had been successfully performed. In the premature 8 were due to placenta prævia or toxæmia, 3 to general patho-

Case.	First diagnosed.	Management.	Cause.	Results to child.
1	38th.	Version failed.	E.L.	Alive. 6¼ lb.
2	32nd.	Version 34th week, spontaneous version again 38th week followed by spont. version to pelvic pole.	Uk.	Alive. 8 lb. 6 oz.
3	33rd.	Diagnosed as vertex later.	Uk.	Alive. 5 lb. 6 oz.
4	34th.	—	Uk.	Alive. 6 lb. 12 oz.

Uk. = Unknown. E.L. = Extended legs.

C.—*Primigravidæ (Premature).*

Case.	First diagnosed.	Management and complications.	Result.
1	30th.	Version failed under anæsthesia at 36th week. Footling presentation at labour 38th.	Child alive. 5 lb. 8 oz.
2	30th.	Toxæmia severe with œdema, version not attempted as fear of injury to placenta 38th week.	Dead. Hydrocephalus; spina bifida.
3	34th.	A.P.H. 34th week.	Stillbirth.
4	32nd.	Version failed 35th week with anæsthesia, cause unknown, patient syphilitic.	Stillbirth.
5	30th.	Version 30th week, not seen again until in labour at 36th week, extended legs.	Alive. 4 lb. 1 oz.
6	36th.	Version failed 37th week, extended legs 38th.	Alive. 5 lb. 12¼ oz.
7	33rd.	38th week prolapsed cord, small pelvic Cæsarean section.	Alive. 4 lb. 13 oz.
8	38th.	Version at 38th week, central placenta prævia, Cæsarean section.	Alive.

D.—*Multiparæ (Premature).*

Case.	First diagnosed.	Management and complications.	Result.
1	28th.	Toxæmia, A.P.H. 28th week, sudden onset of labour, extended legs, cord prolapsed.	Lived 4 hours.
2	28th.	Cardiac disease, 36th week.	Alive. 5 lb. 4¼ oz.
3	26th.	27th week, cause unknown.	Stillbirth.
4	26th.	Placenta prævia, hæmorrhage, 26th week.	Stillbirth.
5	30th.	33rd week, cause unknown.	Did not survive.
6	28th.	Version at 32nd week, again rotated version failed at 36th week and labour began.	Alive. Spina bifida. 6 lb. 15 oz.
7	32nd.	A.P.H., central placenta prævia, induction of labour 32nd week.	Stillbirth.
8	32nd.	Placenta prævia, A.P.H., version and foot brought down.	Lived 14 hrs. Mother died of broncho-pneumonia.
9	—	25th week induction, pulmonary hæmorrhage.	Stillbirth.
10	—	Placenta prævia, version, and delivery 28th week.	Lived 2 days.

logical conditions, and 1 to contracted pelvis with prolapsed cord in which Cæsarean section was performed. In 3 cases labour followed within a few days after version had been attempted or performed.

Seven *fœtal deaths* occurred in the cases of head presentations due to fœtal distress and application of forceps at term. In all of these spontaneous version had taken place some weeks before term. The other deaths were due to early onset of labour where the fœtus was not viable.

Extended Legs.—The chief factor which influences the persistence of pelvic presentations is extended legs, where the lower limbs act as a brace to prevent the natural flexion of the spine taking place. This is one of the most obstinate conditions with which we have to deal, and the most common cause of failure to perform version. X ray examinations have demonstrated the extension of the lower limbs and back. If the spine of the fœtus is curved and the limbs flexed rotation easily takes place. Any interference with this attitude may influence the persistence of pelvic presentations. In some cases it cannot be overcome by anæsthesia, which to a certain extent renders the performance of version easy by relaxing the resistance of the abdominal and uterine walls. Although manipulations under anæsthesia cannot in every case alter the abnormal attitude of the fœtus, it may alter later spontaneously to a head presentation.

Diagnosis of Pelvic Presentations during Pregnancy.

Special attention must be paid to the mobility, roundness, and hardness of the head in the fundus of the uterus, and to the groove of the neck together with the absence of this pole from the lower uterine zone. It must be remembered, however, that in cases of extended legs the pelvic pole is compact and hard, and easily mistaken for the cephalic pole, more especially when it is deeply engaged in the cavity of the maternal pelvis.

We did not find the localisation of fœtal heart sounds round the umbilicus to be a reliable guide. The diagnosis in a large number of the cases was confirmed or contradicted by X ray examinations, and accurate information as to the attitude of the fœtus was obtained, more especially in cases of persistent pelvic presentations in which the fœtal spine was seen to be extended, and attempts at version failed, owing to the rigid condition of the spine and lower limbs.

We are much indebted to Dr. Ulysses Williams and Sister Cooper for their keen enthusiasm and help in procuring skiagraphs. So far no harmful results to the fœtus have been observed as a result of exposure to X rays.

The weeks in which spontaneous version occurred were charted as near as possible to a particular week, and although no doubt errors and mistakes in diagnosis have occurred the observations have been carried out with the expenditure of much time and care on the part of the staff. There are gaps in the diagnosis in some cases owing to the patients failing to attend at regular intervals for abdominal examination. Calculations as to the date of pregnancy were based on the menstrual period as being, of all the unreliable methods, the most reliable. Confirmation was gained by estimating the size and height of the uterus, and the relation of the presenting part to the maternal pelvis.

Treatment of Pelvic Presentations during Pregnancy.

Since spontaneous version occurs so frequently it is as well to leave the fœtus alone to adjust itself in the earlier weeks, and as spontaneous version as a rule takes place between the twenty-eighth and thirty-fourth weeks no attempt at interference should be made before the latter date. If version is easily performed it would in all probability have taken place spontaneously, and experience has shown that in some cases of failure spontaneous version has occurred subsequently. If the pelvic presentation persists in a primigravida after the thirty-sixth week version is advisable, as it may prevent complications in labour, or failure may at least give an indication of difficulties ahead. In multiparæ version is seldom indicated, as in a number of cases where it has been performed the fœtus has again rotated on its axis. In cases of elderly primigravidæ in which version has failed owing to extension of the legs, delivery by Cæsarean section should be considered, as the results to the fœtus are otherwise unsatisfactory.

The chief dangers of version are the bringing on of premature labour by sensitising the uterus, strangulation of the cord, and separation of the placenta by undue manipulation with consequent formation of retro-placental hæmatoma and death of the fœtus.

Summary.

This investigation has not clearly disclosed the factors which influence pelvic presentations. Deformities of the fœtus can be eliminated to a large extent as only one case of hydrocephalus was observed. The length and weight of the fœtus, or the length of the umbilical cord, have been shown to be of little value as determinant factors in spontaneous version or in the prevention of version. Excessive liquor amnii may be a factor, but, as the percentage of cases was small, much importance cannot be given to it. Twins, for their better accommodation, have a tendency for one fœtus to occupy the lower portion of the uterus with its pelvic pole. The occurrence of pelvic deliveries is frequently due to the premature onset of labour. Deformities of the pelvis are not a marked factor as only two were found in 33 pelvic deliveries. Other cases of pelvic contraction corresponded in frequency with those found in the control cases. There were 21 cases of induction of labour, mainly for fœtal and pelvic disproportion or for cardiac and pulmonary diseases, 8 in primigravidæ and 13 in multiparæ. With two exceptions the disproportion cases resulted in head deliveries.

It was observed that in a considerable number of cases the occiput failed to rotate to the front early in labour, and many of these required manual rotation. Globularity in the shape of the uterus has been given as a cause of pelvic presentations, but our investigations furnish no new information regarding this hypothesis. It is difficult to estimate the degree of globularity of the uterus during pregnancy with any flexed standard; in pelvic polar presentations the effect is difficult to separate from the cause. In cases of extended legs there can be little globularity present. The influence of placenta prævia is difficult to estimate, owing to the frequency of interrupted pregnancies and the complication of treatment by version to bring about a footling presentation. There were only two cases in which death of the fœtus might be associated with a pelvic presentation. Tumours occurred in three cases, and in all these spontaneous cephalic version took place. Prematurity is closely associated with pelvic presentations at delivery, owing to the onset of labour occurring before the fœtus has had time to right itself by spontaneous cephalic version. According to our experience this frequently takes place. The onset of premature labour occurs, as it were, at a time when the fœtus is more or less in an unstable position. Had pregnancy advanced the fœtus would have been more likely to settle down in a permanent head presentation, say, after the thirty-fourth or thirty-sixth week.

While abnormal presentations can, in some cases, be assigned to specific causes, no reason can be ascribed for the vast majority. Why a fœtus which starts with a vertex presentation should be spontaneously transposed into a breech presentation, or why one starting with a breech should be spontaneously transposed into a vertex, or why a vertex should become a breech and then be re-transposed into a vertex, is at present an inscrutable mystery. The development of antenatal work is likely to extend our knowledge of these strange happenings.

We desire to direct special attention to the table containing details of the case of spontaneous version from breech to vertex. This proves that, in most instances, nature may be trusted to do what is needful. If, however, spontaneous version is deferred beyond the thirty-sixth week, it is usually wise to resort to version. It may be necessary to perform version in some cases of pelvic presentations in order to estimate the relation of the fœtal head to the diameters of the maternal pelvis.

The results of these investigations show the value and importance of antenatal work. It is only by careful and continuous examination of the pregnant woman from an early stage that we can hope to discover the causes leading to obstetric abnormalities —a prolific cause of morbidity and death in childbirth.

MULTIPLE ABORTIVE CASES OF ENCEPHALITIS LETHARGICA.

BY C. O. STALLYBRASS, M.D. LOND., D.P.H.,
ASSISTANT M.O.H., LIVERPOOL;
AND
A. S. McNEIL, L.R.C.P. & S. EDIN.

IT has often been stated that multiple cases of encephalitis in one house are very rare. In view of the wide extension of encephalitis in Lancashire and Cheshire at the present time, the following associated groups which have been observed by us are of interest. In one household four cases which were regarded as encephalitis have occurred, in another three cases affecting three generations, and in a third household the father and son-in-law were affected.

In the first two instances attention was directed to the household through the occurrence of one well-marked case. Upon inquiry, other and preceding cases came to light who had not sought medical advice. In all instances, however, the occurrence of nystagmus (in eight of the nine cases) or other focal signs points to the sickness from which they have been suffering having also been encephalitis.

Group I.—Mrs. D., aged 21. Slight fever; pulse 136; frontal headache and sleeplessness followed by intense drowsiness for three or four nights and days, muscular twitchings accompanied by sharp pains, nystagmus and strabismus, constipation and dirty tongue. Inquiries showed that her mother, aged 50, and grandmother, aged 80, had previously been ill, the onsets dating back 10 days and 21 days respectively. The mother had general weakness and feeling of faintness and noticed that she was dropping things; she was feverish for some days and had a sore-throat. The grandmother had headache and marked drowsiness; lay in bed for three days sleeping most of the time. One day she felt "as if a brown veil were over her face" obscuring vision. Nystagmus was present in both cases.

Group II.—M. M. B., aged 21. Had an attack in February, 1923, of what was then regarded as influenza, with pain and weakness in the legs. She had a similar attack in February last and continued in indifferent health till March 25th, when she had severe headache, marked drowsiness combined with inability to sleep, aching and weakness in the legs. Nystagmus is present. About a month ago Mrs. C., sister-in-law of the patient, felt as if she had no energy; definite lethargy. Now appears well except that nystagmus is present. A fortnight later Mrs. B., the step-mother, suffered from headache and sleeplessness and felt tired. Says that her symptoms resembled those of Mrs. C. Definite ptosis and nystagmus are now present. Baby B., aged 11 months, step-sister, had diarrhœa, which lasted a few days, and marked irritability, also retraction of the head and nuchal tenderness which raised suspicions of cerebrospinal meningitis. This passed off spontaneously in a few days, but the child is now sleeping more than usual.

Group III.—A. J. E., aged 60. Diarrhœa for three days, followed by headache and nocturnal restlessness; general weakness. When seen at the end of the week nystagmus was present and persists. His son-in-law, 25 years, also suffered from headache, diarrhœa, and slight fever (up to 100° F.); nystagmus is also present.

It may be added that all three groups of cases are immediately adjacent to each other and have occurred during March, 1924. The following group of cases was seen on May 22nd last:—

Group IV.—L. E., aged 7. Onset May 15th. Vomiting and headache, some abdominal pain and diarrhœa. Sleeping continually, nocturnal delirium. Diplopia on May 21st. Nystagmus present.

D. E., aged 10. Onset May 20th. Headache, feverish, slightly delirious one night. Nystagmus.

E. E., aged 8. Onset May 21st. Severe headache. Flushed, but at times cyanotic. Rambling delusions, saw birds flying in through the door. Diplopia, but no strabismus or nystagmus.

When examining the last case the mother volunteered the statement that about Christmas, 1920, she had a similar illness, that she was three weeks in bed, very ill and "saw monkeys and birds." She has never been well since then. Has headaches, is very nervous, and sleeping very badly. Recently the headaches have been worse, and she has been abnormally sleepy. There can be little doubt that in 1920 she suffered from an attack of encephalitis which was missed, and during a slight relapse she became infective and infected her three children, none escaping. The three children were removed to hospital and all made good recoveries without any further developments.

Several other cases of a similar character have come to light, but they have been sporadic. The nystagmus has to be looked for, but is quite definite when found.

Attention was directed to the occurrence of these abortive cases of encephalitis by Kling and Liljenquist[1]; Fyfe[2] reported four ambulatory cases amongst children belonging to one school; and one of us[3] has reported five cases, of which four were abortive, affecting teachers in the infants' department of a school. In Liverpool during 1923, 9 per cent. of cases were found to have been associated with a preceding case. In two instances two cases occurred in one household, two other cases were cousins, and next-door neighbours were affected on three occasions. It would appear that abortive cases are much more frequent than is generally recognised, but that they do not seek medical advice or are regarded as gastric influenza, &c. Numerous cases of post-encephalitic conditions have also come to light within the past few years in which a history of an attack similar to those given above has been obtained. The occurrence of nystagmus during convalescence gives a clear guide to the nature of the sickness suffered from.

During the spring of 1923 a considerable outbreak of encephalitis lethargica affected Liverpool and vicinity, the Wirral area in Cheshire and the western side of South Lancashire being simultaneously affected. This year there has been an extensive outbreak in the south-eastern area of Lancashire and the north-eastern area of Cheshire, Manchester in the centre of this district being especially attacked. The area affected last year has largely escaped this year, and it seems not improbable that the area surrounding Liverpool has been immunised to a considerable extent.

The phenomenon is similar to that reported by Wickman[4] and W. Wernstedt[5] in Sweden in relation to epidemic poliomyelitis, with which disease epidemic encephalitis presents the closest epidemiological analogies. The latter states:—

> "A comparison between the localisation of the principal centres of the large epidemics of infantile paralysis thus displays: (1) that in most places the new and old centres are immediately adjacent to each other; and (2) that, notwithstanding this, only a few scattered cases of infantile paralysis were observed during 1911 within the limits of the old centres, while, *on the other hand*, in 1905 only a few scattered cases occurred in those places which during 1911 became the seats of the large foci."

Draper[6] states "as a rule localities which have been visited one year by an epidemic of poliomyelitis have fewer or no cases the next year." Although many mild cases have been reported in Liverpool this year, it would appear that this observation is proving roughly true with regard to encephalitis, but one cannot expect that the immunity produced by an epidemic in a large town would be effective throughout its whole area in the manner that may be produced in a small rural community.

Treatment of Pelvic Presentations during Pregnancy.

Since spontaneous version occurs so frequently it is as well to leave the fœtus alone to adjust itself in the earlier weeks, and as spontaneous version as a rule takes place between the twenty-eighth and thirty-fourth weeks no attempt at interference should be made before the latter date. If version is easily performed it would in all probability have taken place spontaneously, and experience has shown that in some cases of failure spontaneous version has occurred subsequently. If the pelvic presentation persists in a primigravida after the thirty-sixth week version is advisable, as it may prevent complications in labour, or failure may at least give an indication of difficulties ahead. In multiparæ version is seldom indicated, as in a number of cases where it has been performed the fœtus has again rotated on its axis. In cases of elderly primigravidæ in which version has failed owing to extension of the legs, delivery by Cæsarean section should be considered, as the results to the fœtus are otherwise unsatisfactory.

The chief dangers of version are the bringing on of premature labour by sensitising the uterus, strangulation of the cord, and separation of the placenta by undue manipulation with consequent formation of retro-placental hæmatoma and death of the fœtus.

Summary.

This investigation has not clearly disclosed the factors which influence pelvic presentations. Deformities of the fœtus can be eliminated to a large extent as only one case of hydrocephalus was observed. The length and weight of the fœtus, or the length of the umbilical cord, have been shown to be of little value as determinant factors in spontaneous version or in the prevention of version. Excessive liquor amnii may be a factor, but, as the percentage of cases was small, much importance cannot be given to it. Twins, for their better accommodation, have a tendency for one fœtus to occupy the lower portion of the uterus with its pelvic pole. The occurrence of pelvic deliveries is frequently due to the premature onset of labour. Deformities of the pelvis are not a marked factor as only two were found in 33 pelvic deliveries. Other cases of pelvic contraction corresponded in frequency with those found in the control cases. There were 21 cases of induction of labour, mainly for fœtal and pelvic disproportion or for cardiac and pulmonary diseases, 8 in primigravidæ and 13 in multiparæ. With two exceptions the disproportion cases resulted in head deliveries.

It was observed that in a considerable number of cases the occiput failed to rotate to the front early in labour, and many of these required manual rotation. Globularity in the shape of the uterus has been given as a cause of pelvic presentations, but our investigations furnish no new information regarding this hypothesis. It is difficult to estimate the degree of globularity of the uterus during pregnancy with any flexed standard; in pelvic polar presentations the effect is difficult to separate from the cause. In cases of extended legs there can be little globularity present. The influence of placenta prævia is difficult to estimate, owing to the frequency of interrupted pregnancies and the complication of treatment by version to bring about a footling presentation. There were only two cases in which death of the fœtus might be associated with a pelvic presentation. Tumours occurred in three cases, and in all these spontaneous cephalic version took place. Prematurity is closely associated with pelvic presentations at delivery, owing to the onset of labour occurring before the fœtus has had time to right itself by spontaneous cephalic version. According to our experience this frequently takes place. The onset of premature labour occurs, as it were, at a time when the fœtus is more or less in an unstable position. Had pregnancy advanced the fœtus would have been more likely to settle down in a permanent head presentation, say, after the thirty-fourth or thirty-sixth week.

While abnormal presentations can, in some cases, be assigned to specific causes, no reason can be ascribed for the vast majority. Why a fœtus which starts with a vertex presentation should be spontaneously transposed into a breech presentation, or why one starting with a breech should be spontaneously transposed into a vertex, or why a vertex should become a breech and then be re-transposed into a vertex, is at present an inscrutable mystery. The development of antenatal work is likely to extend our knowledge of these strange happenings.

We desire to direct special attention to the table containing details of the case of spontaneous version from breech to vertex. This proves that, in most instances, nature may be trusted to do what is needful. If, however, spontaneous version is deferred beyond the thirty-sixth week, it is usually wise to resort to version. It may be necessary to perform version in some cases of pelvic presentations in order to estimate the relation of the fœtal head to the diameters of the maternal pelvis.

The results of these investigations show the value and importance of antenatal work. It is only by careful and continuous examination of the pregnant woman from an early stage that we can hope to discover the causes leading to obstetric abnormalities —a prolific cause of morbidity and death in childbirth.

MULTIPLE ABORTIVE CASES OF ENCEPHALITIS LETHARGICA.

By C. O. STALLYBRASS, M.D. Lond., D.P.H.,
Assistant M.O.H., Liverpool;
and
A. S. McNEIL, L.R.C.P. & S. Edin.

It has often been stated that multiple cases of encephalitis in one house are very rare. In view of the wide extension of encephalitis in Lancashire and Cheshire at the present time, the following associated groups which have been observed by us are of interest. In one household four cases which were regarded as encephalitis have occurred, in another three cases affecting three generations, and in a third household the father and son-in-law were affected.

In the first two instances attention was directed to the household through the occurrence of one well-marked case. Upon inquiry, other and preceding cases came to light who had not sought medical advice. In all instances, however, the occurrence of nystagmus (in eight of the nine cases) or other focal signs points to the sickness from which they have been suffering having also been encephalitis.

Group I.—Mrs. D., aged 21. Slight fever; pulse 136; frontal headache and sleeplessness followed by intense drowsiness for three or four nights and days, muscular twitchings accompanied by sharp pains, nystagmus and strabismus, constipation and dirty tongue. Inquiries showed that her mother, aged 50, and grandmother, aged 80, had previously been ill, the onsets dating back 10 days and 21 days respectively. The mother had general weakness and feeling of faintness and noticed that she was dropping things; she was feverish for some days and had a sore-throat. The grandmother had headache and marked drowsiness; lay in bed for three days sleeping most of the time. One day she felt "as if a brown veil were over her face" obscuring vision. Nystagmus was present in both cases.

Group II.—M. M. B., aged 21. Had an attack in February, 1923, of what was then regarded as influenza, with pain and weakness in the legs. She had a similar attack in February last and continued in indifferent health till March 25th, when she had severe headache, marked drowsiness combined with inability to sleep, aching and weakness in the legs. Nystagmus is present. About a month ago Mrs. C., sister-in-law of the patient, felt as if she had no energy; definite lethargy. Now appears well except that nystagmus is present. A fortnight later Mrs. B., the step-mother, suffered from headache and sleeplessness and felt tired. Says that her symptoms resembled those of Mrs. C. Definite ptosis and nystagmus are now present. Baby B., aged 14 months, step-sister, had diarrhœa, which lasted a few days, and marked irritability, also retraction of the head and nuchal tenderness which raised suspicions of cerebrospinal meningitis. This passed off spontaneously in a few days, but the child is now sleeping more than usual.

Group III.—A. J. E., aged 60. Diarrhœa for three days, followed by headache and nocturnal restlessness: general weakness. When seen at the end of the week nystagmus was present and persists. His son-in-law, 25 years, also suffered from headache, diarrhœa, and slight fever (up to 100° F.); nystagmus is also present.

It may be added that all three groups of cases are immediately adjacent to each other and have occurred during March, 1924. The following group of cases was seen on May 22nd last:—

Group IV.—L. E., aged 7. Onset May 15th. Vomiting and headache, some abdominal pain and diarrhœa. Sleeping continually, nocturnal delirium. Diplopia on May 21st. Nystagmus present.

D. E., aged 10. Onset May 29th. Headache, feverish, slightly delirious one night. Nystagmus.

R. E., aged 8. Onset May 21st. Severe headache, flushed, but at times cyanotic. Rambling delusions, saw birds flying in through the door. Diplopia, but no strabismus or nystagmus.

When examining the last case the mother volunteered the statement that about Christmas, 1920, she had a similar illness, that she was three weeks in bed, very ill and "saw monkeys and birds." She has never been well since then. Has headaches, is very nervous, and sleeping very badly. Recently the headaches have been worse, and she has been abnormally sleepy. There can be little doubt that in 1920 she suffered from an attack of encephalitis which was missed, and during a slight relapse she became infective and infected her three children, none escaping. The three children were removed to hospital and all made good recoveries without any further developments.

Several other cases of a similar character have come to light, but they have been sporadic. The nystagmus has to be looked for, but is quite definite when found.

Attention was directed to the occurrence of these abortive cases of encephalitis by Kling and Liljenquist[1]; Fyfe[2] reported four ambulatory cases amongst children belonging to one school; and one of us[3] has reported five cases, of which four were abortive, affecting teachers in the infants' department of a school. In Liverpool during 1923, 9 per cent. of cases were found to have been associated with a preceding case. In two instances two cases occurred in one household, two other cases were cousins, and next-door neighbours were affected on three occasions. It would appear that abortive cases are much more frequent than is generally recognised, but that they do not seek medical advice or are regarded as gastric influenza, &c. Numerous cases of post-encephalitic conditions have also come to light within the past few years in which a history of an attack similar to those given above has been obtained. The occurrence of nystagmus during convalescence gives a clear guide to the nature of the sickness suffered from.

During the spring of 1923 a considerable outbreak of encephalitis lethargica affected Liverpool and vicinity, the Wirral area in Cheshire and the western side of South Lancashire being simultaneously affected. This year there has been an extensive outbreak in the south-eastern area of Lancashire and the north-eastern area of Cheshire, Manchester in the centre of this district being especially attacked. The area affected last year has largely escaped this year, and it seems not improbable that the area surrounding Liverpool has been immunised to a considerable extent.

The phenomenon is similar to that reported by Wickman[4] and W. Wernstedt[5] in Sweden in relation to epidemic poliomyelitis, with which disease epidemic encephalitis presents the closest epidemiological analogies. The latter states:—

> "A comparison between the localisation of the principal centres of the large epidemics of infantile paralysis thus displays: (1) that in most places the new and old centres are immediately adjacent to each other; and (2) that, notwithstanding this, only a few scattered cases of infantile paralysis were observed during 1911 within the limits of the old centres, while, on the other hand, in 1905 only a few scattered cases occurred in those places which during 1911 became the seats of the large foci."

Draper[6] states "as a rule localities which have been visited one year by an epidemic of poliomyelitis have fewer or no cases the next year." Although many mild cases have been reported in Liverpool this year, it would appear that this observation is proving roughly true with regard to encephalitis, but one cannot expect that the immunity produced by an epidemic in a large town would be effective throughout its whole area in the manner that may be produced in a small rural community.

logical conditions, and 1 to contracted pelvis with prolapsed cord in which Cæsarean section was performed. In 3 cases labour followed within a few days after version had been attempted or performed.

Seven *fœtal deaths* occurred in the cases of head presentations due to fœtal distress and application of forceps at term. In all of these spontaneous version had taken place some weeks before term. The other deaths were due to early onset of labour where the fœtus was not viable.

Extended Legs.—The chief factor which influences the persistence of pelvic presentations is extended legs, where the lower limbs act as a brace to prevent the natural flexion of the spine taking place. This is one of the most obstinate conditions with which we have to deal, and the most common cause of failure to perform version. X ray examinations have demonstrated the extension of the lower limbs and back. If the spine of the fœtus is curved and the limbs flexed rotation easily takes place. Any interference with this attitude may influence the persistence of pelvic presentations. In some cases it cannot be overcome by anæsthesia, which to a certain extent renders the performance of version easy by relaxing the resistance of the abdominal and uterine walls. Although manipulations under anæsthesia cannot in every case alter the abnormal attitude of the fœtus, it may alter later spontaneously to a head presentation.

Diagnosis of Pelvic Presentations during Pregnancy.

Special attention must be paid to the mobility, roundness, and hardness of the head in the fundus of the uterus, and to the groove of the neck together with the absence of this pole from the lower uterine zone. It must be remembered, however, that in cases of extended legs the pelvic pole is compact and hard, and easily mistaken for the cephalic pole, more especially when it is deeply engaged in the cavity of the maternal pelvis.

We did not find the localisation of fœtal heart sounds round the umbilicus to be a reliable guide. The diagnosis in a large number of the cases was confirmed or contradicted by X ray examinations, and accurate information as to the attitude of the fœtus was obtained, more especially in cases of persistent pelvic presentations in which the fœtal spine was seen to be extended, and attempts at version failed, owing to the rigid condition of the spine and lower limbs.

We are much indebted to Dr. Ulysses Williams and Sister Cooper for their keen enthusiasm and help in procuring skiagraphs. So far no harmful results to the fœtus have been observed as a result of exposure to X rays.

The weeks in which spontaneous version occurred were charted as near as possible to a particular week, and although no doubt errors and mistakes in diagnosis have occurred the observations have been carried out with the expenditure of much time and care on the part of the staff. There are gaps in the diagnosis in some cases owing to the patients failing to attend at regular intervals for abdominal examination. Calculations as to the date of pregnancy were based on the menstrual period as being, of all the unreliable methods, the most reliable. Confirmation was gained by estimating the size and height of the uterus, and the relation of the presenting part to the maternal pelvis.

Treatment of Pelvic Presentations during Pregnancy.

Since spontaneous version occurs so frequently it is as well to leave the fœtus alone to adjust itself in the earlier weeks, and as spontaneous version as a rule takes place between the twenty-eighth and thirty-fourth weeks no attempt at interference should be made before the latter date. If version is easily performed it would in all probability have taken place spontaneously, and experience has shown that in some cases of failure spontaneous version has occurred subsequently. If the pelvic presentation persists in a primigravida after the thirty-sixth week version is advisable, as it may prevent complications in labour, or failure may at least give an indication of difficulties ahead. In multiparæ version is seldom indicated, as in a number of cases where it has been performed the fœtus has again rotated on its axis. In cases of elderly primigravidæ in which version has failed owing to extension of the legs, delivery by Cæsarean section should be considered, as the results to the fœtus are otherwise unsatisfactory.

The chief dangers of version are the bringing on of premature labour by sensitising the uterus, strangulation of the cord, and separation of the placenta by undue manipulation with consequent formation of retro-placental hæmatoma and death of the fœtus.

Summary.

This investigation has not clearly disclosed the factors which influence pelvic presentations. Deformities of the fœtus can be eliminated to a large extent as only one case of hydrocephalus was observed. The length and weight of the fœtus, or the length of the umbilical cord, have been shown to be of little value as determinant factors in spontaneous version or in the prevention of version. Excessive liquor amnii may be a factor, but, as the percentage of cases was small, much importance cannot be given to it. Twins, for their better accommodation, have a tendency for one fœtus to occupy the lower portion of the uterus with its pelvic pole. The occurrence of pelvic deliveries is frequently due to the premature onset of labour. Deformities of the pelvis are not a marked factor as only two were found in 33 pelvic deliveries. Other cases of pelvic contraction corresponded in frequency with those found in the control cases. There were 21 cases of induction of labour, mainly for fœtal and pelvic disproportion or for cardiac and pulmonary diseases, 8 in primigravidæ and 13 in multiparæ. With two exceptions the disproportion cases resulted in head deliveries.

It was observed that in a considerable number of cases the occiput failed to rotate to the front early in labour, and many of these required manual rotation. Globularity in the shape of the uterus has been given as a cause of pelvic presentations, but our investigations furnish no new information regarding this hypothesis. It is difficult to estimate the degree of globularity of the uterus during pregnancy with any flexed standard; in pelvic polar presentations the effect is difficult to separate from the cause. In cases of extended legs there can be little globularity present. The influence of placenta prævia is difficult to estimate, owing to the frequency of interrupted pregnancies and the complication of treatment by version to bring about a footling presentation. There were only two cases in which death of the fœtus might be associated with a pelvic presentation. Tumours occurred in three cases, and in all these spontaneous cephalic version took place. Prematurity is closely associated with pelvic presentations at delivery, owing to the onset of labour occurring before the fœtus has had time to right itself by spontaneous cephalic version. According to our experience this frequently takes place. The onset of premature labour occurs, as it were, at a time when the fœtus is more or less in an unstable position. Had pregnancy advanced the fœtus would have been more likely to settle down in a permanent head presentation, say, after the thirty-fourth or thirty-sixth week.

While abnormal presentations can, in some cases, be assigned to specific causes, no reason can be ascribed for the vast majority. Why a fœtus which starts with a vertex presentation should be spontaneously transposed into a breech presentation, or why one starting with a breech should be spontaneously transposed into a vertex, or why a vertex should become a breech and then be re-transposed into a vertex, is at present an inscrutable mystery. The development of antenatal work is likely to extend our knowledge of these strange happenings.

We desire to direct special attention to the table containing details of the case of spontaneous version from breech to vertex. This proves that, in most instances, nature may be trusted to do what is needful. If, however, spontaneous version is deferred beyond the thirty-sixth week, it is usually wise to resort to version. It may be necessary to perform version in some cases of pelvic presentations in order to estimate the relation of the fœtal head to the diameters of the maternal pelvis.

able all day, the internal piles are greatly reduced in size, and when they do occasionally protrude a little after a constipated motion are easily reduced and do not prolapse again. I have no feeling of "bearing-down," no bleeding, and no burning sensation.

I am unable to say how the treatment acts. The B.P. does not include pitch, the nearest approach to it being tar (pix liquida). Hale-White (1918) states: "Some of its constituents are excreted by mucous membranes, especially the bronchial, on which it acts as a disinfectant stimulating expectorant."

A CASE OF

RUPTURE OF MUSCULAR BELLY OF BICEPS BRACHII DUE TO DIRECT VIOLENCE.

BY GEORGE A. MASON, M.B., B.S. DURH.,
CASUALTY OFFICER, ROYAL NORTHERN HOSPITAL, LONDON.

CASES of ruptured muscles, apart from lacerations, are sufficiently uncommon to be of interest, and the present instance of rupture of a portion of the muscular belly of the biceps brachii seems worth recording.

E. P., aged 34, spinster. She was seen first on Jan. 22nd, 1924, complaining of injury to the right arm, sustained about an hour previously. As she was stepping off a bed on to a chair she tripped, and whilst trying to push away the chair with her right hand she missed it, and the back of the chair hit the inner side of the right arm. The blow was followed by a very violent pain, which she likened to a cut, and she noticed a "gap" in her muscle. On examination there was an obvious gap in the inner portion of the muscular belly of the right biceps brachii in its lower third. This gap was very painful to the touch; it could be felt to widen when the muscle was actively contracted, and to diminish when in the fully relaxed position—in full flexion and supination. The full ranges of movements were present, but associated with pain, and a definite diminution in power.

Treatment.—The muscle was immobilised in its fully relaxed position, and a compress of lotio plumbi c. opio applied. Two days later the gap was no longer obvious, owing to the evidence of bruising of the skin and subcutaneous tissues, but was still definitely palpable. The compress was reapplied, the arm re-fixed, and the patient advised to undergo operation for repair of the muscle. This was carried out on Jan. 28th, six days after the injury.

Operation.—Dr. Benzecry induced anæsthesia with chloroform and maintained it with open ether. The limb was fixed to an arm table, fully supinated, and at right angles to the body. A "hockey stick" incision about six inches long was made over the right biceps in the vicinity of the rupture. The ecchymosis was found to be purely subcutaneous and not to extend beneath the deep fascia, which was opened in the line of the skin incision. The muscle sheath was opened over the site of the rupture, and the severed fibres at once exposed to view. There was no evidence of either blood-clot or effusion between the ends of the fibres, which were quite cleanly divided. The severance just involved that portion of the belly internal to the mesial septum, and did not extend right through the thickness of the muscle, a few fibres posteriorly being still intact. The severed portions were carefully reapproximated with interrupted sutures of catgut, going through the whole thickness of the divided half of the muscle. The muscle sheath was closed with catgut sutures and the skin and fascia closed in layers with the same material. A firm dry dressing was applied and the arm bandaged with the forearm fixed in full flexion and supination. The wound was quite healed twelve days later and massage commenced. After a further seven days this was supplemented by active and passive movements. On March 14th, 1924, or about six weeks after the accident, the arm being satisfactory in every respect, the patient was discharged.

Comments.

1. Presumably the muscle must have been in a state of active contraction when it received the blow. It is difficult to conceive of a flaccid muscle rupturing under such circumstances. 2. The loss of movement immediately after the accident was almost negligible. 3. The clean-cut appearance of the severed edges of the muscle, the absence of any infusion, and the limitation of the bruising to the skin and subcutaneous tissues may be usual in such cases, but occasioned the writer considerable surprise. 4. The "hockey stick" incision gave satisfactory exposure, obviated the use of retractors, and consequently is of great help where the operator is unassisted, as in this case.

Reviews and Notices of Books.

ON THE BREAST.

By DUNCAN C. L. FITZWILLIAMS, C.M.G., M.D., Ch.M., F.R.C.S. London: Heinemann. 1924. Pp. xv. + 440. 30s.

THE purpose of a large monograph upon a single small portion of the body may be presumed to be to present in an accessible form all the known facts concerning the part which may throw light upon the pathology and treatment of the diseases to which it is subject. It is disappointing, therefore, to find at the outset that the author of this book regards it as unnecessary to include "in a book whose primary object is to deal with the surgery of the breast" any account of the physiology of that organ. The physiology of the breast is a difficult and complicated subject, but it is so intimately bound up with the pathology of the breast, and therefore with its surgery, that this omission is to be regarded as unfortunate. Since more than 50 pages are devoted to the interesting, but relatively unimportant, subject of congenital abnormality and gynæcomastia, lack of balance is one of the first impressions received by the reader. This is not, however, a charge that can be levelled at the remainder of the book, provided that it be understood that few authoritative statements upon pathological problems are to be expected. The book is packed with accurate clinical observations and bears evidence throughout of extensive clinical experience and wide reading on the part of the author. The various pathological conditions found in the breast are dealt with serially, and each receives its just modicum of attention. The arrangement is in some respects peculiar, and reflects the uncertainty upon many pathological points with which the author is evidently troubled. Thus sections upon a condition called "lobar mastitis" and upon "chronic mastitis in the male," are separated by nearly a hundred pages from the section dealing with "chronic interstitial mastitis" in the female. As to cysts of the breast, the author leaves the subject in almost the same confusion as enveloped it in the days of Sir Astley Cooper. However, if the author's pathological judgments are obscure, his clinical pronouncements are assured, and these, being based upon wide experience, are undoubtedly of the greatest value.

The illustrations, no list of which is vouchsafed, are numerous and consist almost entirely of line drawings. These are admirably adapted for presenting certain aspects of the breast; the 33 drawings, for instance, of supernumerary and aberrant breasts are almost uniformly clear and interesting. It may be doubted, however, whether the curious object depicted on page 45 as growing upon the thigh of a man is really a mammary gland at all; the text contains no reference to this intriguing case. The majority of the drawings of pathological specimens are so rough that they convey little to anyone not already very familiar with the subjects represented. It is not part of the author's plan to give any attention to the histology of the diseases described. The book does contain reproductions of three microscopic sections borrowed from other authors, but it is difficult to see why these three in particular should have been chosen to the exclusion of all others.

Mr. Fitzwilliams is to be congratulated upon a gallant attempt to fill what he feels to be a gap in medical literature. The statement in the preface, however, that no book on the breast has appeared for 20 years is not wholly correct, for a monograph of about the same extent as the present one was published last year and was reviewed in THE LANCET of Oct. 6th, 1923. No surgeon can fail to be interested and informed by reading either monograph, but the book which will materially advance knowledge of diseases of the breast, for those who are fully acquainted with the literature, still remains to be written.

Clinical and Laboratory Notes.

A NOTE ON FIVE CASES OF EPIDEMIC PLEURISY.

By Eric I. Lloyd, M.B., B.Ch. Camb., F.R.C.S. Eng.,
RESIDENT MEDICAL SUPERINTENDENT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

The Lancet has recently published two communications [1] [2] dealing with the above, and it is hoped that the following notes of a small epidemic amongst the nursing staff of the Hospital for Sick Children, Great Ormond-street, will be of interest. This epidemic was strikingly similar to that described by Williamson as occurring at the country branch of the Paddington Green Children's Hospital, and was contemporary with it. It is curious that the last four patients were nurses from the same ward (we have eight large "general" wards), although there was no such illness amongst the children in the ward from which they came or elsewhere in the hospital.

General Characteristics of the Cases of Epidemic Pleurisy.

No. of case.	Date of onset and duration of illness.	Symptoms at onset.	Headache.	Abdominal pain.	Pain in chest.	Friction sounds detected.	Degree of pyrexia.	Course.
1.	10/6/24. 32 days.	"Not feeling well." Abdominal pain and pain on breathing.	Severe, and lasting about 10 days.	Severe.	Severe.	4th day.	104° on 4th day.	Temp. normal on 5th day, but rose to 103° on 10th day and again on 17th day. Afterwards uneventful.
2.	14/6/24. 23 days.	"Pain in chest."	Moderately severe.	Nil.	Present.	4th day.	103° on 1st day.	Temp. normal on 5th day. On 12th day rose to 102°. Uneventful afterwards.
3.	5/7/24. 12 days.	"Feeling ill." Pain in chest next day.	Present.	,,	,,	? 2nd day.	103·6° on 4th day.	No relapse. Convalescence uninterrupted.
4.	9/7/24. 6 days.	"Headache and pain in chest."	Severe.	,,	,,	9th day.	103° on 4th day.	Ditto.
5.	12/7/24. 14 days.	"Sudden attack of severe abdominal pain and pain on breathing."	Present.	Severe.	,,	Never heard.	103° on 1st day.	Ditto.

The five examples so closely resemble those already described in The Lancet that it is unnecessary to do more than to indicate their general characteristics in tabular form.

Pain in the chest and headache were the usual complaints, but Cases 1 and 5 at their onset closely simulated an early acute appendicitis for the first 12 hours, and one of them had some right rectus rigidity. The pain caused by deep breathing was so severe that the patients would not willingly indulge in it, and the probability is that pleural friction was present in all five cases, but escaped detection in some owing to the quiet respiration enforced by pain. For the same reason it was difficult to be certain of the absence of other abnormal physical signs in the chest, but as the maximum rate of respiration in three patients was 28 and in two 32, the lung substance cannot have been extensively involved; there was also an entire absence of cough. Apart from the relapses in Cases 1 and 2 (vide table) convalescence was uninterrupted, and there have been, so far, no after-effects.

I am indebted to Dr. F. J. Poynton and Dr. J. H. Thursfield for permission to publish this note.

A CASE OF HERNIA OF THE OVARY.

By W. H. Simmons, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond.

The following case of hernia of the ovary I believe sufficiently uncommon to prove of interest.

A female child, aged 3, was brought to hospital, her mother complaining that a small lump had appeared and persisted in the groin for about the last year. On examination a movable oval tumour, about half an inch in length and a quarter of an inch in width, was felt at about the position of the right external ring. There was little or no sensibility to be demonstrated. It rolled easily under the skin, but could not be moved over the deep structures. There appeared to be a slight impulse on crying.

The child was admitted and the inguinal canal explored by Mr. A. J. R. O'Brien. A hernial sac was found and when opened the tumour proved to be the ovary. An elongated extension of the broad ligament was present, and at about the middle of this a thickened band was adherent to the sac. This was freed, when the ovary slipped easily back into the abdomen. The sac was excised and recovery has been uneventful.

Gold Coast Hospital, Korley Bu, Accra.

A NOTE ON THE TREATMENT OF HÆMORRHOIDS BY PITCH TAKEN INTERNALLY.

By H. W. Webber, M.S., M.D. Lond.,
SURGEON, P. AND O. STEAM NAVIGATION COMPANY.

It seems to me that a note of a personal experience of the above treatment may be of interest.

I have been a sufferer from intero-external piles about 40 years, and the condition has got worse with advancing age. Recently the boatswain of the ship of which I am surgeon, hearing of my complaint, volunteered to cure me if I would follow his treatment. I assented.

At nearly every evacuation there was a protrusion of the size of a bunch of currants. I reduced it every time after smearing with ung. gallæ c. opio and ung. zinci, equal parts, washed the anus well, and practised as far as possible voluntary contraction of the sphincter muscles. The trouble did not improve, and often I had to reduce the prolapsed mass two, three, or more times a day. The anus was, moreover, in a chronic condition of discomfort. On April 12th the boatswain sent along about a dozen pitch pills rolled by himself. I commenced the treatment. An average-sized pill weighed 10 gr. I took one with my tea at 6.30 A.M., and one with afternoon tea at 4 P.M. Improvement was noticeable in about a week, and on April 24th, after a constipated motion passed with much straining, there was no prolapse, the first time for many years. Now, May 9th, I am comfort-the average systolic and pulse pressures of the boys were appreciably higher than in a more easy-going school, whilst the pulse-rate was reduced in compensation.

---

[1] Williamson, Bruce: The Lancet, 1924, ii., 64.
[2] Sutherland, G. A.: Ibid., 194.

It will be seen that Dr. Stocks has made observations upon a number of important points and it is possible that some of his findings will be challenged. In accuracy of method and clearness of exposition the memoir reaches the usual standard of the Galton Laboratory, which is very high praise and in itself adequate reason for congratulating the author.

The Principles of Vital Statistics.

By I. S. Falk, Ph.D., Department of Public Health, Yale University. London and Philadelphia: W. B. Saunders Company. 1923. Pp. 258. 12*s.* 6*d.*

This little book describes the method of taking a census, the principal averages used in vital statistics, and some of the more important source of statistical fallacies. It is intended mainly for American readers and does not show much familiarity with modern statistical methods, but it is clearly written and can be read with advantage by most medical men—unless they are hypersensitive to violations of the rules of old-fashioned English grammar.

Cytology.

An Introduction to the Study of Cytology. By L. Doncaster. Second edition, revised by J. Gray. Cambridge: University Press. 1924. With 24 plates and 31 text figures. Pp. 280. 21*s.*

Prof. Leonard Doncaster died soon after the publication of this popular book in 1920. It has been revised for a second edition by Dr. J. Gray, who has added a certain amount of fresh material, especially on the experimental side with which he is specially familiar. There is no need to commend the book to our readers. Pending the new edition which is promised of Prof. E. B. Wilson's "The Cell in Development and Inheritance"—and perhaps even then—it is certainly the best available book on a subject which in some parts has advanced so wonderfully in recent years. The chapter on the rôle of the cytoplasm is of special interest. It indicates a line forward which by general consent is likely to be fruitful. What is remarkable about the book is the fact that the contents deal only with a limited section of the subject named in the title. By far the greater part is occupied by germ-cells, fertilisation, and inheritance, and anyone who looks in it for a discussion of the cytology of secretion—surely at least as important if a less dramatic subject—will be disappointed. Unless the scope of the book is altered we would suggest that the title should be reconsidered in the third edition.

The price of the book strains our goodwill, and the descriptions of some of the plates are printed on their backs—an inconvenient arrangement.

Functional Testing of the Eye.

Die Funktionsprüfung des Auges. By Dr. W. Wick, Senior Surgeon of the Eye Clinic at Düsseldorf. Berlin: S. Karger. With 90 figures. Pp. 146. 5·40 gold marks.

This little book contains an account of refraction in theory and practice, including the shadow test, the astigmatic fan, and the ophthalmometer; an account of tests for the field of vision, in which, however, there is no mention of the modern modifications of the perimeter for testing the light sense: a plan resembling, but apparently inferior, to Perceval's test is mentioned; and sections on binocular vision, squint, and the detection of simulation follow. The book ends with a chapter on the physiology and pathology of the pupil, illustrated by useful diagrams, and appears to be a useful elementary guide to its subject.

Manipulation de Chimie Colloidale.

By W. Ostwald. Translated by Edmond Vellinger. Paris: Gauthier Villars. 1924. Pp. 201. Fr.6·50.

The German edition of this work is well known to most teachers. The translator in his preface states that he has attempted to adhere to the original German conception of the book and that he hopes to have rendered service to all French workers in the field of colloidal chemistry. That he will have accomplished his object there can be no doubt, since the whole spirit of the book is reproduced in the French language. The methods of preparing, testing, and experimenting with all the common colloidal solutions are fully described, and the book merits success.

Forensic Medicine.

Practical Forensic Medicine. A Police Surgeon's Emergency Guide. Third edition. By C. Graham Grant, V.D., L.R.C.P. & S. Edin., Lieut.-Col. R.A.M.C. (T.); Barrister-at-Law, Gray's Inn; Ex-Divisional Surgeon, H. and Thames Divisions, Metropolitan Police; Ex-Surgeon, Poplar Hospital; Clerk of Arraigns, Central Criminal Court. London: H. K. Lewis and Co., Ltd. 1924. Pp. 98. 4*s.* 6*d.*

This little manual, now in its third edition, contains a considerable amount of information of a practical type. The police surgeon faced with emergency work has to consider not only the immediate treatment of the case, but also possible future legal proceedings; he will find in this little pocket-book a wealth of sound advice by one who has had years of experience in police work. The material is well arranged and the writer may be congratulated on having set forth so much information within so small a space. The section on poisoning is sound, but details of treatment are occasionally so brief as to be difficult to interpret. Emphasis might be laid on the importance of washing out the stomach with the antidote, especially as there is often great difficulty in swallowing, and time is an important factor in many cases. The indications for general restorative treatment might be given briefly and the use of antagonistic drugs. In connexion with strychnine poisoning there is no mention of chloral hydrate. A glossary of trade names for various chemical substances might also be added with great advantage. Medical men are made familiar in the course of their training with the scientific names of substances, but when a patient is brought by his mates having swallowed a substance described as "spent acid," "oil of tar," or "butter of antimony" for example, much valuable time may be lost in determining the exact nature of the poison in question. A pronouncement as to a medical man's duty in a case of attempted suicide who refuses and resists treatment might also have been given. The adoption of these suggestions. in the subsequent issue that will be called for, would not materially increase the bulk of the book and would make it even more useful to those harassed, patient, and competent medical officers for whom it is intended.

A Handbook of Medical Jurisprudence and Toxicology. Fifth edition, revised. By William A. Brend, M.A. Camb., M.D., B.Sc. (Lond., of the Inner Temple, Barrister-at-Law; Lecturer on Forensic Medicine, Charing Cross Hospital; Medical Referee under the Workmen's Compensation Act. London: Charles Griffin and Co. 1924. Pp. 317. 10*s.* 6*d.*

This volume is too well known to require any lengthy review. The present edition has been brought up to date, and new matter introduced such as the recent legislation affecting medical men.

A BIBLIOGRAPHY OF SIR THOMAS BROWNE, KT., M.D.

By GEOFFREY KEYNES, M.A., M.D., F.R.C.S. Cambridge: At the University Press. 1924. Pp. 256. 42*s*.

To review a bibliography is not easy, for the work is such that if it is well done the reviewer must know much less of the subject than does the bibliographer. To lovers of Sir Thomas Browne, Mr. Geoffrey Keynes's work will be a source of great pleasure, while he gives a reproduction of a hitherto unpublished portrait of Sir Thomas and of the only known portrait of that admirable woman, Dorothy Browne, his wife. (See figure.) There is an appendix dealing with the writings of Dr. Edward Browne (of whom the late Sir Norman Moore has written), and another one giving an account of Simon Wilkin, the printer and publisher of Norwich to whom we owe the best edition of the collected works of Browne, an edition published 1835–36. The book is dedicated to the memory of William Osler, and were he alive to see it no one would appreciate it more at its proper worth than that cultivated and charming physician who had many of the characteristics of the scholar physician whom he loved so well.

Reduced reproduction of the frontispiece of Mr. Keynes's "Bibliography of Sir Thomas Browne."

(By permission of the Cambridge University Press.)

A STATISTICAL STUDY OF BLOOD PRESSURE.

Blood Pressure in Early Life: A Statistical Study. By PERCY STOCKS, M.D., D.P.H., assisted by M. NOEL KARN. Cambridge: At the University Press. 1924. Pp. 88. 12*s*.

THIS addition to the series of research memoirs, issued by the Department of Applied Statistics of University College, contains a careful study of blood pressure readings by Dr. Percy Stocks. The author deals with material covering the period from childhood to early middle life, and prefaces his statistical analysis with a critical consideration of the various methods of measurement. In his opinion, the auscultatory method is much more reliable than the palpatory, and he finds that the latter method gives readings for systolic pressure averaging 14 mm. less than those of the auscultatory method in young adults. For diastolic pressure, Dr. Stocks finds the best index to be the end of the third phase of sound, marking the change from a clear to a dull sound, audible on gradually releasing the pressure of the armlet. The changes which occur in pressure and pulse-rate on rising from sitting to standing posture vary much in different individuals; the mean effect in males is a rise of 3 mm. in systolic and of 10 mm. in diastolic pressure. The average increase of pulse-rate is 7·5 beats and there is a fall of 7 mm. in pulse pressure. In females there is on the average no increase in systolic pressure and that of diastolic pressure is about 5 mm. The changes in pulse-rate and pulse pressure are similar to those observed in males. Dr. Stocks did not find any evidence that these reactions could be used as an index of physical fitness, but he does not discuss Flack's work on this point.

Both racial and social differentiation were found to be associated with differences of average systolic pressure, but Dr. Stocks did not find any evidence in support of the commonly accepted opinion that blood pressure increases throughout life. Up to 11 years of age the mean systolic pressure rises uniformly, and during adolescence the gradient is temporarily increased, but the pressure attains a uniform adult level at about 18 years of age, showing no further tendency to increase up to the age of 35–40. The diastolic pressure reaches a maximum at about 20 and then falls slightly until the age of 35 years. Pulse pressure increases uniformly to the age of 15 years, during adolescence attains a high maximum at 16–18, then falls to its original level by 20, and thereafter slowly increases up to the age of 40. Blood pressure is correlated with bodily development apart from age, and the author provides graphs and tables to define the limits of probable normality for persons of known age, weight, stature, and pulse-rates. In this way the range of variability may be reduced, but is still considerable, since other factors, such as social class and heredity, are involved. Regular physical exercise tends to keep the diastolic pressure at a lower level, but there is little evidence of correlation between vital capacity or efficiency in tests of respiratory force and blood pressure. The influence of psychological factors upon blood pressure is considerable. In schools where a strict discipline was maintained

THE LANCET.

LONDON: SATURDAY, AUGUST 9, 1924.

THE PREVENTION OF DISEASE.

The Presidential Address at the meeting of the British Association for the Advancement of Science, which opened this week in Toronto, was delivered by Major-General Sir David Bruce, President of the Association, who with characteristic simplicity estimated the honour of the position which he enjoyed as a recognition through him of the magnificent work performed by medical officers during the war, both for the prevention of disease and the alleviation of pain and suffering. He took for his subject the prevention of disease and treated it, in spite of its vastness, in a symmetrical and succinct manner, so that a heterogeneous mass of information was assorted into a coherent story; and to-day, when far-reaching researches are being undertaken at many widely separated centres, when the old knowledge is being sifted and sorted for rejection or for adaptation to the new, and when all society is in a state that is producing new factors for good or ill, this is an achievement.

Sir David Bruce first dealt with the infectious diseases, which he subdivided into three groups, bacterial, protozoal, and undetermined, in accordance with their ætiology. A glance at the comparative size and importance of these groups forms remarkable testimony to the research work which has been and is being carried on by men whose names, like the name of David Bruce, occur repeatedly wherever a writer or a speaker attempts to tell the story of the progress of science. Prevention as a sequel to cause is displayed in each group. As soon as it was recognised that infectious diseases are caused by living germs a series of magnificent discoveries were made, and tuberculosis, typhoid fever, cholera, diphtheria, tetanus, and Malta fever, all in turn, yielded their secrets and became susceptible to scientific prophylaxis. In the second great group of infectious diseases, the protozoal, the discovery of the malaria parasites inaugurated research which led to the discovery of the causes of Texas fever, nagana or tsetse-fly disease, sleeping sickness, yellow fever, and kala-azar, and in some proportion to the extent to which the natural history of these different diseases has been worked out is it evident that prevention can be attempted. But in addition to the bacterial and protozoal infectious diseases there is a third and large class, styled by Sir David Bruce the undetermined group, where no parasite, bacterial or protozoal, has been identified, in which category is included the common diseases such as measles, scarlet fever, and small-pox, as well as dengue fever, sand-fly fever, and the vaguely defined condition known as trench fever. To this undetermined class belongs foot-and-mouth disease, whose incidence is so disastrous and so costly upon animals, as well as the other plagues which are assumed to be due to a filter-passing virus, though in the case of foot-and-mouth disease there is now good evidence that the living germ has been identified. Concerning each disease, as it falls under one or other of these groups, Sir David Bruce furnished brief and accurate information, attributing to the various workers their share in the task of discovery, and indicating the lines on which medical science could devise schemes of prevention with the coöperation of the intelligent public.

From this point the speaker went on to indicate that scientific advance had not been limited to the infectious groups, but could be recorded in conditions which did not belong to that category, notably in diseases due to dietetic deficiency. In words that would have appealed to Rousseau, Sir David Bruce pointed out that the untutored savage, living on the natural fruits of the earth and the chase, knew no deficiency disease; the habits of civilisation with its unnatural environments and sophisticated foodstuffs being associated with these conditions. An exemption similar to that enjoyed by the savage may, however, be the lot of man when he is living in comfort and drawing his food-supply from far-ranging sources, which allow of full variety in diet; but where, in what purport to be civilised conditions, adults and children live in unnatural circumstances—such as prevail in institutions—or where armies are on active service, or when extremes of climate have to be encountered, deficiency diseases appear; and where young children, whose range of diet is restricted, have to go short of the needful provision these diseases develop with particular mischief to the race, for social inefficiency results if the deprivation is severe or prolonged. And in speaking of the treatment of deficiency diseases Sir David Bruce laid full stress on the value of sunlight, quoting here the researches into the interaction of diet and light in the prevention and cure of rickets in infants which were carried out by Dr. Harriette Chick and her colleagues in Vienna, and which from time to time have been fully recorded in The Lancet. The Presidential Address fully justified the choice of a physician for its delivery, for it placed medicine in the forefront of the activities which make for good in the world.

◆

FUNDAMENTAL CANCER KNOWLEDGE.

The fourth instalment of the summaries issued by the Departmental Committee on Cancer has just been sent out by the Ministry of Health to local authorities throughout the country, and is available for general information at a nominal cost. The pamphlet is abstracted on page 285. It is the result of an invitation to Dr. J. A. Murray, Director of the Imperial Cancer Research Fund, in consultation with other members of the Committee, to furnish a brief review of the main lines followed by experimental cancer research in recent years, and of the broad conclusions, negative as well as positive, which may now be adduced. The circular, as we have noted, is addressed to local authorities in England and Wales, and it may be asked: What has experimental research to do with the practical hygiene of the community? It is well that this question should be put and answered. For a generation or more all the scientific work on the cancer problem was conducted without noise or clamour, almost without making itself audible at all to the ear of popular opinion. If examples were necessary in support of this statement we should mention the recent statement of a well-known dietarian that advanced investigators are agreed that cancer is "due to a toxic irritated and stimulated condition of the system"; another, from a well-known author, who asserts, without the slightest fear of contradiction, that cancer "can only grow from a cancer

There is no doubt that the volume has proved of great value both to students and practitioners. Although in important matters, where a full knowledge of a subject is required, it is necessary to consult the larger text-books, especially as to details of cases, Dr. Brend's book may be relied on to supply anyone with a sound general view of the majority of forensic and toxicological questions.

The volume is of convenient size; it is perhaps a pity that a slightly larger type was not used, especially from the point of view of the student. At the stage of his career when he is reading a book of this kind, he is or should be spending several hours a day reading for his final examinations. Authors and publishers alike should, therefore, bear in mind questions of eye-strain.

MANAGEMENT OF DIABETES.

By GEORGE A. HARROP, Jr., M.D., Assistant Visiting Physician, New York Presbyterian Hospital. New York: Paul B. Hoeber, Inc. 1924. Pp. 190. $2.00.

THIS manual represents the teaching which has been given to some 600 physicians, as well as nurses, who have visited the Presbyterian Hospital in order to learn how to use insulin. A short account is given of the elements of normal and disturbed metabolism and of the acid-base mechanism. The properties of insulin are described and the plan of treatment used at the Presbyterian Hospital is explained. Four illustrative cases are then set out with the details of the management of the insulin. All the cases seem mild according to the standards of hospital practice in this country. An attempt is made to keep the urine sugar-free, but no special effort is made to maintain a normal blood-sugar. The calorie value of the diet is a high one and the carbohydrate ration used for the mild cases is ½ g. of sugar for normal body-weight. Details are given of the method of treating coma, and the importance of searching for infections in every case of diabetes is insisted on. Various recipes and good diet tables are given.

There is an accurate index, and the book should be useful to practitioners.

THE PHARMACISTS' BOTANY.

By GEORGE B. RIGG, Ph.D., Associate Professor of Botany, University of Washington. New York: The Macmillan Company. 1924. Pp. 303. 16s.

BOTANY as a subject for the qualifying examination in pharmacy does not, as a rule, find favour among professional pharmacists and students in this country. Whether this is due to the method of presentation or not it is difficult to say, but in view of the close connexion between botany and materia medica it is not unreasonable to suppose that the failure on the part of the pharmacist to appreciate the study of botany may be due to lack of imagination on the part of his teacher. Dr. Rigg states that his book is the result of 14 years of "teaching pharmacy botany —eliminating non-essentials so often stressed—and seeking ever more practical means of presenting the subject to the best advantage with the least waste." He has, on the whole, succeeded in producing a concise and interesting manual. In his desire to be brief he has not always maintained the balance between text and illustrations; thus the description of karyokinesis is confined to about a dozen lines of text, though it is accompanied by a figure composed of 12 plates, inadequately described; on the other hand, the descriptions of the microscopic appearance of cross-sections of typical monocotyledonous and dicotyledonous stems could have been made considerably clearer by a few more illustrations of tracheids, bordered pits, and the like, since the use of such terms without illustrations is not likely to convey much to the reader. The chapter devoted to the classification of seed plants is the longest in the book and is the one which brings the subject in closest relation to pharmacy, since the brief description given to each family is followed by a list of official drugs belonging to such family. Perhaps the least satisfactory chapter is that dealing with physiological processes; the student's conception of osmosis, for example, is hardly likely to be improved by the statement that "the tendency of the solute is to diffuse toward the solution containing the greater number of particles in solution." Again, the inclusion of a number of essential oils in the section devoted to fatty oils and their inter-relationship with carbohydrates is unfortunate: in this chapter also are to be found a number of minor misprints, such as salingenin for saligenin, glutanimic for glutaminic, lycine for lysine, and amolytic for amylolytic. The frequent use of trivial names common in America, such as kinnikinnick, pipissewa, squash, &c., is liable to frighten the English reader, but the author has wisely provided an excellent index of botanical synonyms, which should remove all difficulty.

The book as a whole presents a praiseworthy attempt to provide the pharmacist with an outline of the subject of botany, written in a concise, intelligible, and attractive manner.

JOURNALS.

ARCHIVIO DI SCIENZE BIOLOGICHE. Vol. V., Nos. 3-4. Napoli. 1924.—This volume contains many interesting articles. Dr. A. Dalla Volta contributes the results of his experiments on the relation between the chemical condition and biological activity of human serum. Both distilled water and ethyl alcohol destroyed the complementary activity; alcohol had a definite coagulating action on the colloidal system represented by the serum.—An article by Dr. A. Roncato shows that the elimination of creatinine in relation to age is very different from that of urea; the two curves often show an opposite direction.—Dr. P. Radaelli found that irradiation of the testicle caused a remarkable disappearance of the spermatozoa about the tenth day; in the preceding period the action of the X rays was shown only in very slight changes in the chromation of these elements.—The influence of the nervous system on the processes of regeneration was investigated by Miss P. Locatelli, who found that the sympathetic system had no influence, but the spinal ganglia had a decided influence. The experiments were made on the tails of *Triton tremalus* and *cristatus* —Dr. G. Viale contributes four papers on energy output in human beings under various experimental conditions, working on similar lines to the late A. D. Waller in this country. He concludes that the same quantity of work performed in a given time modifies the heart condition, respiratory exchange, and energy output in a different way according as the work is done slowly or quickly, as by raising a heavy or light weight, the extent of the movement remaining constant. The ouput of the human motor, like the mechanical, is greater when the muscles have to perform a lighter task, even if the rate is more frequent. The physiological cost is less when the force necessary for executing the work is small, and the work is more economical if the task is distributed even though the actual movement is more extensive.—The action of alcohol on the muscular contractions in frogs is the subject of a paper by Dr. C. Pulcher, who concludes that it causes an increase in the tonic phenomenon of the contraction.—Dr. G. Quagliariello publishes the communication which was made to the International Congress of Physiology at Edinburgh in 1923 on theories of muscular contraction.—Drs. M. Bolaffio and Artom record their experiments on the physiology of the nervous system of the human fœtus, from which they obtained some definite and striking results.

VASCULAR REACTIONS OF THE SKIN TO INJURY.

THE phenomenon of "dermographism" or "factitious urticaria" has recently been studied by Thomas Lewis,[1] who pointed out that the "wheal-reaction" that occurs in this condition, even on light stroking of the skin, is merely an exaggerated physiological response, a similar reaction being produced on a normal skin by stronger or repeated stimuli of the same kind. In conjunction with Ronald Grant,[2] he has now published the results of experiments on the production of wheals by means of solutions of histamine. It is shown first that reactions to stroke and histamine present similar time relations, and that the reaction consists in each case of (1) a local dilatation of the minute skin vessels, which, since it occurs when the circulation has been arrested, is a primary dilatation of these vessels; (2) a surrounding flush, due to widespread dilatation of the skin arterioles; (3) an exudation of fluid into the tissues, the rate at which exudation occurs being largely governed by the rate of blood flow through the tissue. This exudation can take place against relatively high external pressures, and is therefore not merely dependent on increased filtration pressure, but on increased permeability of the vessel wall. As a result of further ingenious experiments, the authors conclude that the primary local dilatation of small vessels is a direct effect and is independent of the nervous system, that the widespread dilatation of the surrounding arterioles is dependent on a local reflex, and that the increased permeability of the vessel wall, like the local vasodilatation, is uncontrolled by the nervous system. The total reaction of the skin, although complex, is identical for both mechanical and chemical stimuli, and also in all probability for a third kind of stimulus—namely, the thermal one, which also leads to whealing if sufficiently strong. It is, therefore, reasonable to suppose that with these three varieties of stimulus there is a common factor on which the actual reaction depends. Without discussing the experimental evidence adduced, we may say that the authors conclude that the wheal-reaction, whether produced in an urticarial person by stroking or in normal skins by stronger mechanical or thermal stimuli, is due to the liberation in the skin of a chemical substance, which acts as a vaso-dilator and at the same time increases the permeability of the vessel wall. They suggest that the same is true of the reactions produced in the skin by burns, ultra-violet light, poisons, such as peptone, mustard-oil, and mustard-gas, certain oils and other vesicants, morphia and atropine, and the substances introduced by biting and stinging insects and hairy plants. It is likely that this chemical substance is histamine or some closely allied product of tissue damage; on the other hand, it may be that histamine, when applied by puncture of the skin, as in the authors' experiments, acts like other poisons, such as morphia, and releases the hypothetical substance from the tissues to which the reaction is directly due. The researches of Dale and Laidlaw[3] on the reaction produced by injection of this substance showed that histamine causes general dilatation of the peripheral small blood-vessels beyond the main arterioles and an increased permeability of their walls, resulting in a great fall of blood pressure and collapse, a condition comparable to anaphylactic and wound shock. It has been sufficiently proved that in secondary wound shock, and in that produced by extensive burns, it is the absorption of the products of the damaged tissue that causes the profound fall of blood pressure and collapse. Bayliss,[4] Cannon, and others have shown that this secondary shock does not occur when the channels of absorption from the area of damaged tissue are closed, and Robertson and Boyd[5] produced a condition of shock in healthy animals by introducing substances recovered from burnt skin.

These researches may obviously have a very important bearing on the phenomena of anaphylaxis, sensitisation, desensitisation, and immunity.

With regard to anaphylaxis, it is possible that the various symptoms that characterise the anaphylactic state, of which an erythemato-urticarial rash is one, are directly due to the production of some histamine-like substance in the tissues, as, indeed, the work of Dale and Laidlaw, already referred to, would suggest. In this connexion it is relevant to refer to those cases in which after severe bruising without laceration of the skin or after an operation with extravasation of blood—e.g., for removal of the breast—there may follow with an interval of about ten days an outbreak of an erythemato-urticarial rash resembling a serum eruption. Dr. Arthur Whitfield has reported two cases of this kind in patients who had been bruised, and we know of the condition having occurred after operations. The interval between the injury or operation and the outbreak of the eruption corresponds closely with that between the injection of a foreign serum and the appearance of a serum-rash. It would seem likely that in these cases some substance is produced in the damaged tissue or extravasated blood which provokes the eruption. The relationship of sensitisation to anaphylaxis is obscure, but, although most examples of sensitisation cannot be regarded as truly anaphylactic, there would seem to be a resemblance between the two conditions. It is important to recognise that there are two main forms of cutaneous reaction occurring in the sensitised state, the erythemato-urticarial and the eczematous. The latter denotes epidermal sensitisation, and is well illustrated by the dermatitis provoked by poison plants and certain chemicals. Both forms of reaction, however, may coexist in the sensitised state, and just as there are persons who are prone to develop urticaria from a variety of causes, so there are those whose epidermis is so sensitive that the application of substances which are innocuous to the normal skin produces in them an acute eczematous reaction. A point of great interest is that a local sensitiveness of certain areas of the skin may exist, so that the sensitising substance may provoke a reaction on one area but not on another. This question of sensitisation must be considered in connexion with the suggestion of Lewis and Grant that the reactions produced in the skin by the substances introduced by biting and stinging insects and certain hairy plants are actually due to some product of tissue damage. In this connexion Cranston Low[6] has proved that the nettle-sting gives rise to a reaction in those who have never previously been stung, and that repeated stinging produces no immunity. It is, therefore, not a sensitisation phenomenon, but a purely mechanical irritation from the puncture of the skin by the hairs on the leaf and the injection of an irritant fluid. But in the case of biting and stinging insects the reactions would seem to be of a different nature. For Boycott has shown that in persons who have never previously been bitten by the rat-flea no reaction is produced when they are bitten for the first time, but after repeated bitings a marked reaction occurs, and this sensitiveness then persists. The same is probably true of certain stinging flies. Moreover, in the case of insect-bites, unlike the nettle-sting, immunity in time is produced, and in a person who is constantly being stung by gnats and mosquitoes, or bitten by fleas and lice, eventually no local reaction results. If the suggestion of Lewis and Grant be correct, some explanation is required as to the meaning of this sensitisation and desensitisation.

Lastly, the question of drug-rashes may be considered. In a large proportion of cases these are not specific, and a number of different drugs may provoke "type-reactions," such as erythema or urticaria, germ, born in the body of one unfortunate to find a home in the body of another unfortunate"; and a third, from a Member of Parliament, who seriously suggests aspirin, salicylates, and liquid paraffin "which have the same root as charcoal" as probable causes of the increased number of cancer cases. The cancer orchestra has now become popular, and it matters very much indeed that the instruments should play in concert, and that if the wind instruments play a trifle too loud the essential motif should not be made obscure to the local authorities.

The policy of the Committee has been to set out broad conclusions, negative as well as positive; what is not known as well as what is known. No one except the workers themselves knows what an ungrateful task it is to draw negative conclusions. A paragraph or two in a report, a few lines in a summary, may be enough to set forth the outcome of experimental work on which the observer has spent time, energy, zeal, and ingenuity. The long and tedious road too often ends in disappointment, and there should be a particular beatitude for those who are willing to admit the negative outcome of the patient work of years; in scientific medicine it is often the humble who inherit the earth. Three hypotheses of the origin of cancer which have been promulgated with force and ability have, we are told, inspired no experiments leading to the production of a new growth of more than a temporary character. The hypothesis that cancer is due to invasion by a parasitic micro-organism; the suggestion that during fœtal life small islands of cells become isolated to take on independent growth later; the assumed resemblance between the division of cancer cells and of germ cells, leading to the inference that cancer growth depends on a reversion to the sexual type of cell division—these conceptions have produced nothing of practical moment, and the tree of research must be judged by its fruits. Equally fruitless has been the research into vitamin deficiency in relation to cancer which the report condenses into a sentence. Deficiency, even when pushed to a dangerous degree, appears to exert no marked influence in retarding growth of transplanted tumours in rats, nor does the presence of a tumour accelerate the onset of the symptoms of this deficiency. Local authorities, deeply concerned as they should be with the nutrition of the community, must bear this in mind. Research on cancer metabolism has so far led practically to nothing. No constant or significant differences have been discovered in the absorption and utilisation of the materials necessary to bodily existence between normal and cancerous animals. Rapidly growing malignant growths may contain a higher proportion of potassium salts and a lower calcium content than corresponding normal tissues, but this feature is not really distinctive, as it is shared by young and embryonic tissues. Here the finding of long and patient research is still quite negative.

But the positive achievement is very definite and not difficult to set out clearly. It has certainly never been so well set out as in this memorandum. Here the year 1915 is memorable; for although under Virchow's inspiration, Tiersch, Waldheim, Diakon, and others had already brought together data in support of the irritation theory of cancer, it was not until 1915 that it became possible by the continued application of tar and other substances to induce the formation of a growth displaying the two typical features of cancer—namely, unlimited power of multiplication and ability to form metastases. This conception has positive results to record; it has been a fruitful conception. The production of cancer in animals by repeated application of tar, based largely on the work of Tsutsui, and of Fibiger and Bang in the mouse, is the most important of these practical results. All animals are not equally susceptible, and while simple tar may initiate true skin cancer in three to four months in a few mice out of a large number, in the majority six to nine months is necessary; and in some animals, again a few in number, no result may be obtained, although tarring be continued for 18 months. Since mice die of old age at about 2 years, irritation to be effective has to be continued through a proportion of their life which corresponds to 20 or 30 years in man—a suggestion which is fully borne out by such accurate human experience as exists, notably that of Dr. A. Scott, of Broxburn, in the Scottish paraffin industry. If tarring be discontinued after three to four months, the cancer develops after a latent period which may be shortened if another form of injury—namely, scarification, is combined with tarring. How close is the analogy between this finding and the association in man of cancer of the tongue with rough tooth-stumps, smoking, and syphilis. Attempts to identify chemically the substance in tar which induces cancer have not yet been successful, beyond its limitation to the fraction boiling at 300°–350° C. It may not be a simple body; arsenious acid is the only pure substance which has so far been used with success as a cancer-producing irritant. The rôle of chemical irritation in the production of cancer has now become very plain indeed, for although two forms of malignant new growth in the rat are constantly associated with the presence of parasites, repeated injection of dried parasites does not produce new growth, and the belief is well founded that it is not the mechanical irritation of the parasite, but the long-continued application of substances excreted by the parasites which is responsible for the result. The local authority, to whom this pamphlet is addressed, will recall the sweep and the mule-spinner in relation to chemical irritation. Another striking fact is the observation that the existence of a cancer produced by tarring or arising spontaneously in a mouse prevents the production of a second malignant tumour by tarring, showing particularly clearly that a tumour produces some alteration in the whole body of the animal in which it is growing.

One fragment of knowledge lies perplexingly on the border-line of the positive and the negative. The infective sarcomata of the domestic fowl, discovered by P. Rous, appear to be transmissible without the intervention of intact cells, and thus to be out of harmony with all other experimental cancer work. The question is raised in the memorandum whether these tumours, if completely freed from a filtrable virus, could still behave as malignant new growths when introduced into the bodies of susceptible animals. If not, they may in reality be in the nature of granulomata dependent for their continued proliferation on the persistence and multiplication of the infecting organism. Here is a question worthy of further investigation. The memorandum will be of special service to those who are surveying experimental cancer investigation as a whole, and considering the directions, new and old, in which particular researches require to be initiated or continued. It is a most valuable memorandum, and wise investigators will realise that the studious calm of its authors in no way belittles the value of their work. For in truth the document is one testimonial to their qualities of patience and perseverance.

VASCULAR REACTIONS OF THE SKIN TO INJURY.

THE phenomenon of "dermographism" or "factitious urticaria" has recently been studied by Thomas Lewis,[1] who pointed out that the "wheal-reaction" that occurs in this condition, even on light stroking of the skin, is merely an exaggerated physiological response, a similar reaction being produced on a normal skin by stronger or repeated stimuli of the same kind. In conjunction with Ronald Grant,[2] he has now published the results of experiments on the production of wheals by means of solutions of histamine. It is shown first that reactions to stroke and histamine present similar time relations, and that the reaction consists in each case of (1) a local dilatation of the minute skin vessels, which, since it occurs when the circulation has been arrested, is a primary dilatation of these vessels; (2) a surrounding flush, due to widespread dilatation of the skin arterioles; (3) an exudation of fluid into the tissues, the rate at which exudation occurs being largely governed by the rate of blood flow through the tissue. This exudation can take place against relatively high external pressures, and is therefore not merely dependent on increased filtration pressure, but on increased permeability of the vessel wall. As a result of further ingenious experiments, the authors conclude that the primary local dilatation of small vessels is a direct effect and is independent of the nervous system, that the widespread dilatation of the surrounding arterioles is dependent on a local reflex, and that the increased permeability of the vessel wall, like the local vasodilatation, is uncontrolled by the nervous system. The total reaction of the skin, although complex, is identical for both mechanical and chemical stimuli, and also in all probability for a third kind of stimulus—namely, the thermal one, which also leads to whealing if sufficiently strong. It is, therefore, reasonable to suppose that with these three varieties of stimulus there is a common factor on which the actual reaction depends. Without discussing the experimental evidence adduced, we may say that the authors conclude that the wheal-reaction, whether produced in an urticarial person by stroking or in normal skins by stronger mechanical or thermal stimuli, is due to the liberation in the skin of a chemical substance, which acts as a vaso-dilator and at the same time increases the permeability of the vessel wall. They suggest that the same is true of the reactions produced in the skin by burns, ultra-violet light, poisons, such as peptone, mustard-oil, and mustard-gas, certain oils and other vesicants, morphia and atropine, and the substances introduced by biting and stinging insects and hairy plants. It is likely that this chemical substance is histamine or some closely allied product of tissue damage; on the other hand, it may be that histamine, when applied by puncture of the skin, as in the authors' experiments, acts like other poisons, such as morphia, and releases the hypothetical substance from the tissues to which the reaction is directly due. The researches of Dale and Laidlaw[3] on the reaction produced by injection of this substance showed that histamine causes general dilatation of the peripheral small blood-vessels beyond the main arterioles and an increased permeability of their walls, resulting in a great fall of blood pressure and collapse, a condition comparable to anaphylactic and wound shock. It has been sufficiently proved that in secondary wound shock, and in that produced by extensive burns, it is the absorption of the products of the damaged tissue that causes the profound fall of blood pressure and collapse. Bayliss,[4] Cannon, [illegible] and others have shown that this secondary shock does not occur when the channels of absorption from the area of damaged tissue are closed, and [illegible] Boyd[5] produced a condition of shock in healthy animals by introducing substances recovered from burnt skin.

These researches may obviously have a very important bearing on the phenomena of anaphylaxis, sensitisation, desensitisation, and immunity.

With regard to anaphylaxis, it is possible that the various symptoms that characterise the anaphylactic state, of which an erythemato-urticarial rash is one, are directly due to the production of some histamine-like substance in the tissues, as, indeed, the work of Dale and Laidlaw, already referred to, would suggest. In this connexion it is relevant to refer to those cases in which after severe bruising without laceration of the skin or after an operation with extravasation of blood—e.g., for removal of the breast—there may follow with an interval of about ten days an outbreak of an erythemato-urticarial rash resembling a serum eruption. Dr. Arthur Whitfield has reported two cases of this kind in patients who had been bruised, and we know of the condition having occurred after operations. The interval between the injury or operation and the outbreak of the eruption corresponds closely with that between the injection of a foreign serum and the appearance of a serum-rash. It would seem likely that in these cases some substance is produced in the damaged tissue or extravasated blood which provokes the eruption. The relationship of sensitisation to anaphylaxis is obscure, but, although most examples of sensitisation cannot be regarded as truly anaphylactic, there would seem to be a resemblance between the two conditions. It is important to recognise that there are two main forms of cutaneous reaction occurring in the sensitised state, the erythemato-urticarial and the eczematous. The latter denotes epidermal sensitisation, and is well illustrated by the dermatitis provoked by poison plants and certain chemicals. Both forms of reaction, however, may coexist in the sensitised state, and just as there are persons who are prone to develop urticaria from a variety of causes, so there are those whose epidermis is so sensitive that the application of substances which are innocuous to the normal skin produces in them an acute eczematous reaction. A point of great interest is that a local sensitiveness of certain areas of the skin may exist, so that the sensitising substance may provoke a reaction on one area but not on another. This question of sensitisation must be considered in connexion with the suggestion of Lewis and Grant that the reactions produced in the skin by the substances introduced by [illegible] stinging insects and certain hairy plants are attributable to some product of tissue damage. In this connexion [illegible] has proved that [illegible] in those who have [illegible] than repeated [illegible] produces an immunity [illegible] therefore, not a sensitisation phenomenon, but a purely mechanical [illegible] from the puncture of the skin by [illegible] and the injection of [illegible] insects the [illegible] nature. [illegible] of a different [illegible] have [illegible] but in persons who [illegible] no reaction [illegible] bitten by the mosquito [illegible] they are bitten for the [illegible] occurs [illegible] a marked reaction [illegible] persists. The [illegible] immunities. [illegible] unlike the [illegible] in a person who [illegible] and mosquitoes [illegible] eventually no local [illegible] Lewis and [illegible] is required [illegible] germ, born in the body of one unfortunate to find a home in the body of another unfortunate"; and a third, from a Member of Parliament, who seriously suggests aspirin, salicylates, and liquid paraffin "which have the same root as charcoal" as probable causes of the increased number of cancer cases. The cancer orchestra has now become popular, and it matters very much indeed that the instruments should play in concert, and that if the wind instruments play a trifle too loud the essential motif should not be made obscure to the local authorities.

The policy of the Committee has been to set out broad conclusions, negative as well as positive; what is not known as well as what is known. No one except the workers themselves knows what an ungrateful task it is to draw negative conclusions. A paragraph or two in a report, a few lines in a summary, may be enough to set forth the outcome of experimental work on which the observer has spent time, energy, zeal, and ingenuity. The long and tedious road too often ends in disappointment, and there should be a particular beatitude for those who are willing to admit the negative outcome of the patient work of years; in scientific medicine it is often the humble who inherit the earth. Three hypotheses of the origin of cancer which have been promulgated with force and ability have, we are told, inspired no experiments leading to the production of a new growth of more than a temporary character. The hypothesis that cancer is due to invasion by a parasitic micro-organism; the suggestion that during fœtal life small islands of cells become isolated to take on independent growth later; the assumed resemblance between the division of cancer cells and of germ cells, leading to the inference that cancer growth depends on a reversion to the sexual type of cell division—these conceptions have produced nothing of practical moment, and the tree of research must be judged by its fruits. Equally fruitless has been the research into vitamin deficiency in relation to cancer which the report condenses into a sentence. Deficiency, even when pushed to a dangerous degree, appears to exert no marked influence in retarding growth of transplanted tumours in rats, nor does the presence of a tumour accelerate the onset of the symptoms of this deficiency. Local authorities, deeply concerned as they should be with the nutrition of the community, must bear this in mind. Research on cancer metabolism has so far led practically to nothing. No constant or significant differences have been discovered in the absorption and utilisation of the materials necessary to bodily existence between normal and cancerous animals. Rapidly growing malignant growths may contain a higher proportion of potassium salts and a lower calcium content than corresponding normal tissues, but this feature is not really distinctive, as it is shared by young and embryonic tissues. Here the finding of long and patient research is still quite negative.

But the positive achievement is very definite and not difficult to set out clearly. It has certainly never been so well set out as in this memorandum. Here the year 1915 is memorable; for although under VIRCHOW'S inspiration, TIERSCH, WALDHEIM, DIAKON, and others had already brought together data in support of the irritation theory of cancer, it was not until 1915 that it became possible by the continued application of tar and other substances to induce the formation of a growth displaying the two typical features of cancer—namely, unlimited power of multiplication and ability to form metastases. This conception has positive results to record; it has been a fruitful conception. The production of cancer in animals by repeated application of tar, based largely on the work of TSUTSUI, and of FIBIGER and BANG in the mouse, is the most important of these practical results. All animals are not equally susceptible, and while simple tar may initiate true skin cancer in three to four months in a few mice out of a large number, in the majority six to nine months is necessary; and in some animals, again a few in number, no result may be obtained, although tarring be continued for 18 months. Since mice die of old age at about 2 years, irritation to be effective has to be continued through a proportion of their life which corresponds to 20 or 30 years in man—a suggestion which is fully borne out by such accurate human experience as exists, notably that of Dr. A. SCOTT, of Broxburn, in the Scottish paraffin industry. If tarring be discontinued after three to four months, the cancer develops after a latent period which may be shortened if another form of injury—namely, scarification, is combined with tarring. How close is the analogy between this finding and the association in man of cancer of the tongue with rough tooth-stumps, smoking, and syphilis. Attempts to identify chemically the substance in tar which induces cancer have not yet been successful, beyond its limitation to the fraction boiling at 300°–350° C. It may not be a simple body; arsenious acid is the only pure substance which has so far been used with success as a cancer-producing irritant. The rôle of chemical irritation in the production of cancer has now become very plain indeed, for although two forms of malignant new growth in the rat are constantly associated with the presence of parasites, repeated injection of dried parasites does not produce new growth, and the belief is well founded that it is not the mechanical irritation of the parasite, but the long-continued application of substances excreted by the parasites which is responsible for the result. The local authority, to whom this pamphlet is addressed, will recall the sweep and the mule-spinner in relation to chemical irritation. Another striking fact is the observation that the existence of a cancer produced by tarring or arising spontaneously in a mouse prevents the production of a second malignant tumour by tarring, showing particularly clearly that a tumour produces some alteration in the whole body of the animal in which it is growing.

One fragment of knowledge lies perplexingly on the border-line of the positive and the negative. The infective sarcomata of the domestic fowl, discovered by P. ROUS, appear to be transmissible without the intervention of intact cells, and thus to be out of harmony with all other experimental cancer work. The question is raised in the memorandum whether these tumours, if completely freed from a filtrable virus, could still behave as malignant new growths when introduced into the bodies of susceptible animals. If not, they may in reality be in the nature of granulomata dependent for their continued proliferation on the persistence and multiplication of the infecting organism. Here is a question worthy of further investigation. The memorandum will be of special service to those who are surveying experimental cancer investigation as a whole, and considering the directions, new and old, in which particular researches require to be initiated or continued. It is a most valuable memorandum, and wise investigators will realise that the studious calm of its authors in no way belittles the value of their work. For in truth the document is one testimonial to their qualities of patience and perseverance.

and towns of Sweden. These investigations do not necessarily invalidate the observations of bacteriologists who have found the bovine tubercle bacillus in a goodly proportion of cases of fatal tuberculosis in childhood. But Dr. Lichtenstein's work is an important addition to the mass of evidence which has accumulated during the last few years, and which points unequivocally to the conclusion that man is the most dangerous source of infection, and that strains of tubercle bacilli not conforming to the characteristic properties of the human type of tubercle bacillus play a comparatively unimportant part in the tuberculosis of man.

A FRENCH HISTORY OF MEDICINE.

THE French have always been in the forefront of the army of writers on the history of medicine. Daniel Le Clerc's "Histoire de Médecine" was published in 1702; he was practically a contemporary of our own Dr. John Freind, physician and politician, who brought out his History of Physick from the time of Galen in 1725; while in more modern times we have N. L. Leclerc, whose excellent "Histoire de la Médecine Arabe" appeared in 1876. Dr. L. Meunier is a worthy follower[1] of his eminent countrymen, and we agree with Prof. Ballet, President of the Société Française d'Histoire de la Médecine, who says in his preface :—

> "For a work upon the history of medicine to find acceptance among medical men who are not indifferent to things of long ago, but who have only little leisure to give to their study, it is necessary for the book to be complete without being too long, without obscurity though of necessity condensed, and without neglecting essentials it should glide lightly over many matters of secondary interest which serve to show up in relief those which really make up the important links of tradition. Such a task is difficult to accomplish, but in my opinion Dr. Meunier may be said to have succeeded as far as is possible."

In a work of only some 600 octavo pages, which covers the whole period from Hippocrates to the end of the nineteenth century, it is impossible to mention everything that might be mentioned, but we have noted one or two places where we think that Dr. Meunier might have added to his facts. For instance, in his fifth book, where he is referring to the editions and translations made at the Renaissance of the works of Hippocrates and Galen, he says that previously all the translations had been made into Latin from an Arabic version. But Hippocrates and Galen had been translated certainly in part and possibly in their entirety in the sixth century, according to Cassiodorus who, in the instructions which he compiled for the use of the monks in his monastery called Vivaria, says:—

> "Quod si vobis non fuerit Graecarum litterarum nota facundia . . . . legite Hippocratem atque Galenum latina lingua conversos id est Therapeutica Galeni . . . . et Hippocratis de Herbis et curis."

It is not quite clear whether the two treatises mentioned by Cassiodorus were the only ones translated, or the only ones which he wanted the monks to read, and we have been unable to find any reference in the Loeb Library to a Hippocratic treatise with a title in Greek corresponding to De Herbis et Curis. Again, when talking of the eighteenth century, Dr. Meunier remarks that John Hunter treated aneurysms by opening the sac and ligation of the vessel above and below, but he makes no mention of the true Hunterian operation, one of the greatest advances in surgery, of tying the vessel at a distance from the aneurysm so as to apply the ligature at a healthy part. We think, too, that in the section on pathogenic microbes, p. 501 et seq., a little more might have been said of Lister's patient and toilsome researches than that "Lister, from about 1869, without any full understanding of the microbic complications of operation wounds, promulgates his system of antiseptic dressings with satisfactory results from now onwards." These, however, are but slight blemishes in an admirable book, and we congratulate both Dr. Meunier and the French Society of the History of Medicine upon its appearance.

THE PATHOGENESIS OF CARDIAC ASTHMA.

THE results of a series of investigations undertaken with a view to explaining the pathogenesis of cardiac asthma are recorded in an important work[1] recently published in Vienna. Having reviewed the clinical picture of this well-known syndrome, the authors conclude, from a survey of the investigations dealing with the subject, that a theory has not been developed which can satisfactorily explain the breathlessness and pulmonary œdema of cardiac asthma. The speed with which the blood flows towards the heart may in a rough way be estimated by observing the flow of blood in a superficial vein of the arm, which has first been emptied by stripping with the finger the vessels in a peripheral direction, and at the same time obstructing the flow at the central end. It was found in many cases of cardiac asthma, by this simple method of examination, that the speed with which the blood flowed through the emptied vein was much increased as compared with a normal subject. If these observations could be confirmed by some exact method of estimating the speed with which the blood flows we should be justified in concluding that the œdema of the lungs in cardiac asthma was due to the failure of the left ventricle to maintain the circulation, and that this was brought about by the sudden increase in the speed with which the blood reaches the right auricle.

Three methods were employed to investigate the blood flow in the patients upon whom observations were being made: (1) the plethysmographic method, a volumetric method by which it is possible to estimate the flow of blood through an extremity in a unit of time; (2) the blood method, which depends upon the difference in the oxygen content of the arterial and venous blood; (3) the gas method, which is the most accurate method of estimating the true minute volume. By employing the last method it is possible to determine the difference in the oxygen content of the blood in the right and left sides of the heart. The plethysmographic method employed by these investigators is not a new one. The technique is simple and the apparatus in no way complicated. The forearm, which is always used in this experiment, is covered with a glove and enclosed in a water-containing receptacle; by means of a Riva-Rocci sphygmomanometer venous stasis is produced in the limb and a rise or fall in volume is recorded on a revolving drum. The time required for the plethysmographic curve to rise after obstructing the venous flow in the limb is taken as an index of the speed with which the blood flows in the superficial veins of the body. The Austrian investigators find that the blood flow towards the heart is quickened by heating the water and retarded when the temperature of the water has been lowered. The plethysmographic curve is a slow-rising one in patients with high blood pressure. In the patient with exophthalmic goitre the rise is a rapid one; in the case with myxœdema, on the other hand, there is little or no rise, depending upon the temperature of the limb. In the patient with cardiac asthma, if the observation is made during the attack, there may be a perpendicular rise of the curve the instant venous stasis is produced, so rapid is the blood flow towards the heart at this time. It is the rule for the curve to rise rapidly in these cases during the attacks, or shortly before. One curve recorded during an attack is given showing no real increase in the blood flow. To confirm the results obtained by the plethysmographic method the oxygen content of from the appearance of which it is impossible to incriminate any particular one. Here, perhaps, the actual cause of the eruption is not the drug itself, but some toxic substance produced by its action on the tissues. Certain drugs, however, may evoke eruptions as specific as those of the eruptive fevers or of the well-defined dermatoses—for example, the halogens, and, above all, antipyrine. These specific forms of cutaneous reaction provide one of the most fascinating problems not only for the clinical dermatologist but also for the physiologist and biochemist. To take a single example, we may cite pityriasis rosea, one typical lesion of which is sufficient for an expert to make a certain diagnosis; that this disease is due to an unknown infective organism is certain, but what are the factors on which the peculiar configuration of the type-lesion and the characteristic distribution of the eruption depend? The morbid histology of the eruptive elements does not help us.

At present we can but recognise that, among the great variety of cutaneous reactions, some, such as certain forms of erythema, urticaria, and eczema, are non-specific, and these may be due not to the direct action on the skin of the various toxins that provoke them, but to substances produced by the poisonous action of the toxins on the tissues; on the other hand, other reactions are absolutely specific for a given toxin, and it is on the variety of these specific reactions that the differential diagnosis of skin diseases largely depends. We can recognise clinically the special characteristics of this or that eruption, and in many cases a diagnosis can be made from a microscopical section, but at present we are absolutely ignorant of the physical and chemical processes that determine the specific differences in these cuti-reactions. It seems to us that light might be thrown on this problem by further research along the lines adopted by Lewis and Grant in their recent experiments.

Annotations.

"Ne quid nimis."

SOCIAL SERVICES IN HOSPITALS.

The report of the Institute of Hospital Almoners for the year 1923 gives an encouraging account of this branch of social service. The income and expenditure account shows a small balance on the right side. During the year 11 students completed the course of training required and received the certificate of the Institute, eight almoners and four assistant almoners trained by the Institute were appointed to various hospitals, 18 candidates were accepted for training, and a fund for scholarships was placed at the disposal of the Institute. It is no light task in these days to administer a social service department of a hospital successfully. Old landmarks have disappeared and a new generation has arisen with new needs and insistent demands. Adaptability to these new needs is essential; the housing problem, parental responsibility, industrial fatigue, the psychology of the worker, these and many other matters come from time to time "within the terms of reference" of the hospital almoner. The report of the social service department of St. Thomas's Hospital for 1923 brings these points into focus from a wide angle. As the report shows, the voluntary hospital is gradually opening its doors to a larger public, highly specialised forms of treatment beyond the scope of the general practitioner tend to increase in number and complexity, special inquiries, such as the one now proceeding in chorea and rheumatism, are opening up new fields of research, the after-care of cancer patients has become more and more a social necessity, and with all these advances the responsibility of the almoner's department increases proportionately. Added to these new developments the needs for financial inquiry, for which the almoner's departments were originally started years ago, call nowadays for especially careful and wise handling. The "new poor" is no political myth: it is the outward expression of post-war conditions which will remain with us in the voluntary hospitals for many a long day. Although it is obviously impossible to comment on the many problems which confront the social service departments in this connexion, one at least needs reference in passing—viz., the inter-relation of the various State grants and voluntary financial aid. The report of the Almoner's Department of Moorfields Eye Hospital emphasises this point. State assistance has, as yet, by no means covered all the cases requiring help even in so well-regulated a field as ophthalmic work. Moorfields treats numbers of myopic children from districts of the Home Counties outside the L.C.C. area where the special education accorded to London children is impossible to obtain owing to the scattered nature of some of the county districts. In such cases there is often no choice between an ordinary elementary school and a resident school for the blind, and coöperation with the hospital social service department is needed to bridge the gap. Another instance of the dovetailing of voluntary effort and State assistance is supplied in the condition of patients who lose their sight between the ages of 35 and 50. These unfortunate patients are too old for training in workshops or other institutions under the education authorities, and too young for the State pensions for the blind, whilst the pensions of the various voluntary organisations are too few to meet the circumstances. In these days it is obvious that patient and social worker alike need the "infection of a good courage."

A GEOGRAPHICAL SURVEY OF HUMAN AND BOVINE TUBERCULOSIS.

In the United States of America the recent rapid decline in the incidence of surgical tuberculosis in childhood has been correlated by some authorities with the wholesale pasteurisation of milk which has been in force for some years in certain towns. It is very doubtful if this deduction is correct, for in certain Norwegian towns the incidence of tuberculosis in childhood has also fallen with dramatic speed during the last few years, although the milk-supply of these towns is not pasteurised. We may not yet be in a position to appraise accurately the importance of the bovine tubercle bacillus in the generation of human tuberculosis, but a recent statistical survey, published by Dr. A. Lichtenstein in *Acta Pædiatrica* for June 16th, would suggest that we may in the past have much overrated the importance of bovine tuberculosis as a source of infection to man. Dr. Lichtenstein investigated the incidence of fatal tuberculosis among children 1 year old and 5 years old in the towns and counties of Sweden, comparing the figures thus obtained with the figures showing the incidence of bovine tuberculosis throughout the country. No connexion whatever could be found between the two series of figures. In the north of Sweden, for example, bovine tuberculosis proved to be practically non-existent, whereas the death-rate from tuberculosis among children was exceptionally high. Dr. Lichtenstein classified the 24 counties of Sweden according to the frequency of bovine tuberculosis, and he found that the 12 worst counties in this respect showed an average incidence of 13·8 cases of tubercle per 10,000 head of cattle, whereas the corresponding figure for the 12 counties with the lowest rate of bovine tuberculosis was only 2·7 per 10,000. In the first group the death-rate from tuberculosis among children under the age of 5 was 14·8 per 10,000, and in the second group it was 12·7 per 10,000. The difference between the human rates was thus very slight in the two groups of counties, although bovine tuberculosis was five times more common in one group than in the other. Dr. Lichtenstein has also compared the death-rate from tuberculosis among children under the age of 5 with the death-rate from tuberculosis at all ages in man, and has found that these two rates run parallel to a remarkable degree in the different counties and towns of Sweden. These investigations do not necessarily invalidate the observations of bacteriologists who have found the bovine tubercle bacillus in a goodly proportion of cases of fatal tuberculosis in childhood. But Dr. Lichtenstein's work is an important addition to the mass of evidence which has accumulated during the last few years, and which points unequivocally to the conclusion that man is the most dangerous source of infection, and that strains of tubercle bacilli not conforming to the characteristic properties of the human type of tubercle bacillus play a comparatively unimportant part in the tuberculosis of man.

A FRENCH HISTORY OF MEDICINE.

THE French have always been in the forefront of the army of writers on the history of medicine. Daniel Le Clerc's "Histoire de Médecine" was published in 1702; he was practically a contemporary of our own Dr. John Freind, physician and politician, who brought out his History of Physick from the time of Galen in 1725; while in more modern times we have N. L. Leclerc, whose excellent "Histoire de la Médecine Arabe" appeared in 1876. Dr. L. Meunier is a worthy follower[1] of his eminent countrymen, and we agree with Prof. Ballet, President of the Société Française d'Histoire de la Médecine, who says in his preface :—

> "For a work upon the history of medicine to find acceptance among medical men who are not indifferent to things of long ago, but who have only little leisure to give to their study, it is necessary for the book to be complete without being too long, without obscurity though of necessity condensed, and without neglecting essentials it should glide lightly over many matters of secondary interest which serve to show up in relief those which really make up the important links of tradition. Such a task is difficult to accomplish, but in my opinion Dr. Meunier may be said to have succeeded as far as is possible."

In a work of only some 600 octavo pages, which covers the whole period from Hippocrates to the end of the nineteenth century, it is impossible to mention everything that might be mentioned, but we have noted one or two places where we think that Dr. Meunier might have added to his facts. For instance, in his fifth book, where he is referring to the editions and translations made at the Renaissance of the works of Hippocrates and Galen, he says that previously all the translations had been made into Latin from an Arabic version. But Hippocrates and Galen had been translated certainly in part and possibly in their entirety in the sixth century, according to Cassiodorus who, in the instructions which he compiled for the use of the monks in his monastery called Vivaria, says :—

> "Quod si vobis non fuerit Graecarum litterarum nota facundia . . . . legite Hippocratem atque Galenum latina lingua conversos id est Therapeutica Galeni . . . . et Hippocratis de Herbis et curis."

It is not quite clear whether the two treatises mentioned by Cassiodorus were the only ones translated, or the only ones which he wanted the monks to read, and we have been unable to find any reference in the Loeb Library to a Hippocratic treatise with a title in Greek corresponding to De Herbis et Curis. Again, when talking of the eighteenth century, Dr. Meunier remarks that John Hunter treated aneurysms by opening the sac and ligation of the vessel above and below, but he makes no mention of the true Hunterian operation, one of the greatest advances in surgery, of tying the vessel at a distance from the aneurysm so as to apply the ligature at a healthy part. We think, too, that in the section on pathogenic microbes, p. 504 et seq., a little more might have been said of Lister's patient and toilsome researches than that "Lister, from about 1869, without any full understanding of the microbic complications of operation wounds, promulgates his system of antiseptic dressings with satisfactory results from now onwards." These, however, are but slight blemishes in an admirable book, and we congratulate both Dr. Meunier and the French Society of the History of Medicine upon its appearance.

THE PATHOGENESIS OF CARDIAC ASTHMA.

THE results of a series of investigations undertaken with a view to explaining the pathogenesis of cardiac asthma are recorded in an important work[1] recently published in Vienna. Having reviewed the clinical picture of this well-known syndrome, the authors conclude, from a survey of the investigations dealing with the subject, that a theory has not been developed which can satisfactorily explain the breathlessness and pulmonary œdema of cardiac asthma. The speed with which the blood flows towards the heart may in a rough way be estimated by observing the flow of blood in a superficial vein of the arm, which has first been emptied by stripping with the finger the vessels in a peripheral direction, and at the same time obstructing the flow at the central end. It was found in many cases of cardiac asthma, by this simple method of examination, that the speed with which the blood flowed through the emptied vein was much increased as compared with a normal subject. If these observations could be confirmed by some exact method of estimating the speed with which the blood flows we should be justified in concluding that the œdema of the lungs in cardiac asthma was due to the failure of the left ventricle to maintain the circulation, and that this was brought about by the sudden increase in the speed with which the blood reaches the right auricle.

Three methods were employed to investigate the blood flow in the patients upon whom observations were being made: (1) the plethysmographic method, a volumetric method by which it is possible to estimate the flow of blood through an extremity in a unit of time; (2) the blood method, which depends upon the difference in the oxygen content of the arterial and venous blood; (3) the gas method, which is the most accurate method of estimating the true minute volume. By employing the last method it is possible to determine the difference in the oxygen content of the blood in the right and left sides of the heart. The plethysmographic method employed by these investigators is not a new one. The technique is simple and the apparatus in no way complicated. The forearm, which is always used in this experiment, is covered with a glove and enclosed in a water-containing receptacle; by means of a Riva-Rocci sphygmomanometer venous stasis is produced in the limb and a rise or fall in volume is recorded on a revolving drum. The time required for the plethysmographic curve to rise after obstructing the venous flow in the limb is taken as an index of the speed with which the blood flows in the superficial veins of the body. The Austrian investigators find that the blood flow towards the heart is quickened by heating the water and retarded when the temperature of the water has been lowered. The plethysmographic curve is a slow-rising one in patients with high blood pressure. In the patient with exophthalmic goitre the rise is a rapid one; in the case with myxœdema, on the other hand, there is little or no rise, depending upon the temperature of the limb. In the patient with cardiac asthma, if the observation is made during the attack, there may be a perpendicular rise of the curve the instant venous stasis is produced, so rapid is the blood flow towards the heart at this time. It is the rule for the curve to rise rapidly in these cases during the attacks, or shortly before. One curve recorded during an attack is given showing no real increase in the blood flow. To confirm the results obtained by the plethysmographic method the oxygen content of the arterial and venous blood was estimated in a similar group of cases. When the blood flow is rapid the difference in the oxygen saturation of the arterial and venous blood should be slight. The observations recorded confirm the results obtained by the plethysmographic method. It is noted that in some the venous blood has a bright red colour and this is attributed to the rapid flow of blood through the capillaries. Observations on the effect of pilocarpin, morphia, adrenalin, and amyl nitrite on the blood flow, determined in this way, are of pharmacological interest and offer a possible explanation of the effect of these drugs in cardiac asthma. These observations and others, based on the recording of the venous pulse in the arms—the so-called penetrating venous pulse—support the view that in the arms the speed of blood flow from the arteries to the veins is altered by heat, cold, rise of blood pressure, certain drugs, and that nervous influences play an important rôle in producing this change.

Further evidence will be necessary if this theory of the pathogenesis of cardiac asthma is to be accepted, for the observations so far have been limited to a study of the blood flow in the arm. An analysis of the true minute volume of the blood—i.e., the volume of blood flowing through the heart in a unit of time—should confirm the results obtained from the plethysmographic and blood methods of estimating blood flow. It was found, in the control cases, that the normal values when the gas method was employed varied between quite wide limits, but that it was possible to conclude from the results in the heart cases that the breathlessness and pulmonary œdema in the patient with cardiac asthma are due to the overloading of the right side of the heart with failure of the left ventricle, brought about by the increase in the volume of blood flowing into the auricles in a unit of time. This very interesting study of the peripheral circulation has advanced our knowledge of a subject which is occupying the minds of many engaged in cardio-vascular research.

INDUSTRIAL SMOKE ABATEMENT.

IN our issue of last week[1] we referred briefly to the efforts now being made in Halifax to prevent excessive smoke from the factory chimneys. Mr. H. G. Clinch, chief smoke inspector, tells us in the annual health report that since the end of 1922 an entirely new procedure has been adopted in dealing with dirty chimneys. Before that date observations were taken at intervals, and in case of excessive emission of black smoke statutory notices were served and prosecutions followed in the event of non-compliance. The present method is to provide owners of boiler plants with technical advice, to prove to them the economy of smokeless combustion, hoping by so doing to obtain coöperation, only using legal proceedings as a last resource. Much trouble is given to the careful inspection of boiler plants, and to the study of the fuel and methods of firing in order to locate the cause of faulty combustion. At first engineering proposals emanating from the health department were regarded with suspicion, but as a result of patient explanation of the principles involved, confidence has been established and owners are now pleased to know that their boiler plants are under supervision. In the past firms have been surprisingly careless of the way in which their coal was used, and cheerfully footed a coal bill amounting to thousands of pounds per annum without ascertaining first the calorific value of the coal used, and secondly, what proportion of this value was being recovered in steam. Sometimes it has been found that 30 per cent. of the heating value of the coal was being wasted through sheer carelessness or ignorance. In one instance an avoidable waste of £1150 per annum from a two-boiler plant was disclosed. Mr. Clinch points out that more coal is probably used in the boiler furnaces than in the houses of Halifax, so that the present campaign is gradually ridding the town of preventable smoke. As a further proof of the guilt of the factory chimneys, he contrasts the blue haze every Sunday, when the domestic chimney is producing its maximum output, with the dismal gloom of the week-days, when the factory chimneys are busy. During 1923 290 observations of factory chimneys for one hour gave an average of 1·9 minutes of dense black smoke. It seems, also, from Mr. Clinch's report that instruments for enabling a reliable estimate to be formed of furnace efficiency are not yet satisfactory, and he thinks that a wall type temperature indicator, showing the heat of the gases in the downtake of every boiler, would be of greater assistance to the fireman than the combustion indicators at present in use, which only warn him of the presence of excess air and tell him nothing about insufficient air. The fireman needs an indicator showing what heat he is actually producing. Mr. Clinch quotes some 15 typical examples showing how cases of faulty combustion were dealt with during the year. Lectures have been delivered at the Workmen's Club to boiler attendants and firemen. Mr. Clinch is most optimistic as to the results of the new system and foresees the time when every manufacturer in Halifax will be his own smoke inspector. It is to be hoped that the example of Halifax will be followed by other factory towns.

DEVELOPMENT OF THE VAGINA.

AT the recent summer meeting at Sheffield of the Anatomical Society Dr. R. N. Burkitt described the conditions in a case in which the vagina was absent, but in which there was reason to suppose that the uterus was present and capable of menstruation. Prof. J. E. Frazer, at the same meeting, showed a specimen in which there were two vaginæ opening in a single normal vulva, each vagina leading to a separate half-uterus, with a normal tube and elongated ovary; a ruptured follicle was present in each ovary. A median septum extended from bladder to rectum, between the two uteri. Those who believe that normal development, as we know it now, will not explain such abnormalities, and those who look to the study of normal development for their explanation were represented in the discussion over these specimens. The two views seem to be at direct variance, but really they are similar views, seen, perhaps, from slightly different angles. The first of the two schools of opinion mentioned above holds that details of organogenetic formation are of little use in fundamental abnormalities, and that inquiry must be pushed back to the causes lying under the lines of development. The second group holds that further research into development will explain such cases, but the only parts of normal organogeny about which we do not know anything are the early and primary parts, in which the form and line of development is laid down. Thus the two groups are really suggesting research in the same direction as the way to find explanation for these large abnormalities. In the particular case of the female pelvic organs, however, there is reason to call for decisive investigation into the actual facts of later formation. Clinicians and pathologists are aware that there are at least two main views in the field about the development of the vagina, to take this organ alone, and there is a tendency to choose one view as more likely than the other, because it seems to fit in with certain aspects of disease. The older view derives the vagina from the Müllerian ducts. This origin is altered at a later stage, according to the second view, by secondary down-growths to form the vagina, the older structure being lost. This secondary alteration of the original state, however, is without proof and demonstration, so far, although it must be confessed that it would fit in, not only with the explanation of cases such as those shown at Sheffield—and with many other pathological conditions—but also with certain facts in comparative anatomy. Nevertheless, it seems only right to point out that this view, however alluring, is at present an unproved assumption, and that there is need for further research into the very important questions concerned.

[1] THE LANCET, August 2nd, p. 240.

CASUALTIES AT WEMBLEY.

SINCE the opening of the British Empire Exhibition in April the medical services, of which we gave an account in THE LANCET of May 31st (p. 1127), have dealt, through the Main Ambulance Station, with over 11,000 casualties occurring in the Exhibition grounds. The cases have been very varied in character and severity, which is to be expected in a community with a changing daily population of between one and three hundred and fifty thousand, and although the majority of the 11,000 cases were trivial, some 300 of these must be classed otherwise. Amongst the latter were the following: gastro-enteritis, 87 (all in one day[1]); fractures, 12; dislocations, 5; perforated duodenal ulcer, 5; appendicitis, 4. The fractures consisted of three of the shaft and one of the neck of the femur, and one of the lower end of the ulna through falling on the hypothenar eminence of the hand, but no fracture was the result of any accident in the Amusement Park. The dislocations were three of the shoulder, all reduced, and patients sent home; and one of the terminal phalanx of the great toe backwards. Among the less serious cases with which the main ambulance station has to deal must be mentioned those persons, old and young, who fall into the lake, and though little harm is done they must be put to bed while their clothes are drying. It was found necessary to accommodate batches of ex-soldier paraplegics for the relief of urinary difficulties. The Amusement Park provides occasional accidents, but few are other than slight, and the menagerie there supplies its quota of wounds from "twisting the lion's tail"—the retaliatory defensive measures of irate bears, monkeys, and other animals. Fatigue auto-intoxication is a common complaint amongst elderly folk and children, following long journeys, frequently undertaken at night with little rest or sleep, combined with unsuitable and irregular meals. They require rest in bed and dieting, and they get both. Headaches require relief and are due to the same cause; aspirin is a sheet anchor and is in frequent demand. Aged men with prostatic trouble, ofttimes leading to distension with overflow, require catheterisation, and elderly females with colotomies or pessary displacements wish re-adjustments. Railway and char-a-banc excursionists with abdominal colic from general over-repletion seek anodynes. When it is stated that over 84,000 ices were sold one day in the Exhibition this is not surprising, as there can be no limitation, except the pocket, to individual desire or capacity. Epileptics and hysterics respectively demand bromides and sympathy. Four midwifery cases are recorded, one in which the woman was in the sixth month of pregnancy and three of premature labour. No case of acute alcoholism has required treatment, and the stomach-pump has found no employment for this purpose. There have been only two deaths since the Exhibition was opened to the public, one the case of an employed workman who died of heart failure and the other through an accident to an employee on Monday last. The four ambulance stations are staffed by men and women belonging to the Order of St. John of Jerusalem and to the British Red Cross Society, and the average daily number of the staff for first-aid work is 95. The nursing staff is supervised by a visiting matron, a sister, and a qualified nurse from the Willesden General Hospital, who are aided by from two to four V.A.D.'s specially chosen on account of their experience. The work of the first-aid nursing staff is deserving of high praise, as it is practically honorary, the members of the two great ambulance societies receiving the purely nominal wage of half-a-crown per day.

HEALTH SERVICES IN MILNROW DISTRICT.

THE attention of the Minister of Health was recently drawn in the House of Commons to the annual report for 1922 of the medical officer of health for the Milnrow district. In this report it was stated that the death-rate was 21·5, or 7·3 higher than in 1921; that infantile mortality was at the rate of 190 per 1000 births; that the smoke nuisance was very bad; and that a more rapid conversion of the sanitary system of water carriage was required. The Minister was asked whether he was aware that the local authority had done nothing in the way of providing working-class houses; that there was no child welfare centre and no district nurse; and that the sanitary inspector had to give most of his time to collecting rates, collecting rents of council houses, and collecting electricity accounts. The Minister replied that representations had already been made to the urban district council with regard to certain matters, and that should the report of the medical officer of health for 1923 reveal no evidence of improved conditions, he proposed to arrange for an inquiry to be held into the sanitary administration of the district. He added that 54 houses were erected by the local authority under the State assisted scheme authorised by the Housing, Town Planning, &c., Act, 1919, and that the council had adopted a scheme for the assistance of private builders under the Housing, &c., Act, 1923.

The report for 1923 has just reached us, and in this Dr. John Chadwick, the medical officer of health, points out that it is the best report which he has yet been able to put before the council, whereas that of 1922 was the worst. There is a gratifying increase in the birth-rate, while the general death-rate from zymotic diseases, the tuberculosis rate, and the infantile mortality-rate are all very much lower, in fact, form a record. Dr. Chadwick observes, as a matter of common experience, that in small districts the vital statistics are apt to vary very greatly from year to year and that the real state of affairs is shown by the average figures for a term of years. These show a satisfactory improvement in Milnrow and indicate that steady and sustained efforts to improve the sanitary conditions of the district are producing the desired results. The death-rate for 1923 was 11·5—the lowest ever recorded in Milnrow—as against 21·5 for 1922. The death-rate for England and Wales for 1923 was 11·6. In 1922 there were 69 cases of scarlet fever with no deaths, as against six cases in 1923. There has only been one death from scarlet fever during the last 12 years. The infantile mortality-rate for 1923 was 50, as against 190 in 1922. There is no marked improvement in the black smoke nuisance. Only four houses—private enterprise—were erected during the year and none were built by the council. Of pail closets, 119 were converted to the water-carriage system during the year. On May 10th, 1923, an inspector from the Ministry of Health investigated the steps being taken to remedy the smoke nuisance. But in spite of the general improvement noted this year, upon which congratulations are due to Dr. Chadwick and his authority, constant vigilance and strenuous effort are still required if this urban district is to reach a high standard of sanitary administration and maintain it.

THE ORAL ADMINISTRATION OF TYPHOID VACCINE.

AT a recent meeting of the Academy of Medicine of Paris Dr. A. Gauthier,[1] who had previously made a communication before the same company on the prophylaxis and treatment of bacillary dysentery by oral administration of the specific vaccine, reported on his experience of this method with typhoid vaccine for prophylactic purposes. The vaccines used were fluid vaccine, Lumière's entero-vaccine, and bili-vaccine. Among 1210 persons who were given the bili-vaccine between May and December, 1923, at Athens and Salonica, not a single case of typhoid developed. Although typhoid is endemic in these two regions Dr. Gauthier did not feel justified in concluding that these results were a proof of the immunising value of buccal vaccination. He therefore determined to employ the method in a circumscribed area in which there was a considerable epidemic of typhoid. Three Greek villages were chosen for the purpose, one in Attica and two in Eubœa, where a general vaccination of the population was carried out by the oral route. The daily dose was 1 c.cm. for an adult, ½ c.cm. for a child aged 2–6 years, and ¼ c.cm. for a child below 2 years. The dose was repeated for three consecutive days and was taken in a little water on an empty stomach. In the Attica village a severe epidemic was brought to an end suddenly and completely, since only one case of typhoid subsequently occurred, and that during the negative phase seven days after administration of the vaccine, in spite of the fact that the source of contagion continued to exist, no measures having been taken to purify the infected water-supply. In the two Eubœan villages only four cases of typhoid occurred after the vaccinations, all during the negative phases, and the epidemic came completely to an end. Encouraging as these results are, Dr. Gauthier is of opinion that the period of trial of this method is not yet terminated. If the value of the method is confirmed by subsequent experience a considerable advance will be made, since it is undeniable that the fear of hypodermic injection and of the consequent reaction, slight as it is, deters the civilian population in various countries from submitting to antityphoid inoculation. At a subsequent meeting of the Academy of Medicine, Dr. C. Achard and Dr. S. Bloch,[2] commenting on Dr. Gauthier's communication, alluded to the encouraging results obtained by Vaillant with oral administration of typhoid vaccine in the Pas de Calais epidemic in 1921, but they seemed to agree with Calmette, who issued a warning against the generalisation of this method in place of injection. They mentioned the case of a nurse who took 28 keratinised pills of entero-vaccine in the prescribed doses in the course of a week, but nevertheless contracted a severe attack of typhoid fever three and a half months later. The complete absence of immunity in her case was probably due to the vaccine not having been absorbed by the mucous membrane. In other cases they gave full doses of typhoid vaccine by mouth (12 c.cm. in the course of 12 days) as well as 5 g. of sulphate of magnesia on the first day to promote a flow of bile into the intestine, but they did not succeed in getting a positive agglutination reaction, although a fixation reaction was obtained at various dates. The fixation reaction may require repeated examinations of the blood, so that in the end oral administration of the vaccine is not simpler than that of injection.

Subscribers wishing to receive the Indexes regularly as published should indicate this desire.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXIII.—THE TREATMENT OF DYSENTERY.

II.—AMŒBIC DYSENTERY.[1]

AN amœbic infection of the intestinal tract gives rise to a great variety of manifestations, and the clinical picture is accordingly considerably less definite than that of bacillary dysentery. Though occurring in both acute and chronic forms, amœbic dysentery is in the majority of cases characterised by a slow and insidious onset and chronic course, with a tendency to occasional exacerbations, during which the patient is acutely ill. The condition often bears a considerable resemblance to that of chronic bacillary dysentery, and a definite diagnosis may be impossible until the presence or absence of amœbæ or their cysts has been determined by the microscopic examination of the stools—an examination which, in the event of negative findings, must be repeated several times before an amœbic infection can be regarded as definitely excluded. Unlike the chronic bacillary form, there may be in amœbic dysentery long intervals, during which all symptoms may disappear, and a state of fair health seems to be established—a circumstance which needs to be borne in mind in assessing the value of any special line of treatment. The occurrence of hepatic abscess or acute hepatitis in the course of chronic dysentery amounts to practical proof of an amœbic infection.

The general management of a case of amœbic dysentery must be regulated by the severity of the symptoms. During the acute phases, characterised by diarrhœa with frequent loose stools containing mucus and blood, the patient should be kept in bed and placed on a strictly fluid diet. There is not the same objection to milk as in acute bacillary dysentery, and it may be given freely. In the absence of acute symptoms it is seldom necessary to confine the patient to bed, though every form of active exertion should be forbidden; nor is it desirable to restrict the diet to fluids, provided that articles of food which are likely to pass through the intestine in undigested form and cause irritation of the lower bowel are avoided. Constipation is often present, and is best corrected by the use of salines.

The pathological diagnosis of an amœbic infection should be at once followed by one or more courses of treatment with emetine, which is a specific remedy for amœbic dysentery in a similar sense to that in which quinine is a specific remedy for malaria. The chief value of emetine lies in its remarkable controlling influence over the more acute manifestations of the disease; as a means of cure in the sense of the complete eradication of the parasites its efficacy is less striking, and failure is not uncommon. Nevertheless, we possess no remedy more potent for the control of amœbiasis, and the pathological diagnosis of an amœbic infection should be followed as a matter of routine by one or more full courses of treatment. A course consists of 12 days' treatment, during which either (*a*) emetine hydrochloride gr. ⅔ are given hypodermically twice daily; or (*b*) gr. 1 is given by mouth, supplemented by gr. ½ hypodermically each day; or (*c*) bismuth-emetine-iodide gr. 3 are given daily by mouth in salol-coated capsules. The result of the treatment must be checked, not only by observing its clinical effects, which in acute cases are often very striking, but by *repeated examinations of the stools* for amœbæ and cysts. A single course seldom effects a cure; when more than one course is required there are advantages in varying the method of administration, and the order given above may conveniently be followed, reserving bismuth-emetine-iodide for the more chronic and intractable cases. It is desirable that, during treatment with emetine, the patient be kept in bed, however slight his symptoms may be, as in these large doses the drug has a definitely depressing action on the heart, which should therefore be spared as far as possible. While taking emetine by the mouth, the patient is given a simple semi-fluid diet, and should be kept strictly at rest for some time both before and after the daily dose, which may conveniently be given an hour after the last meal. Vomiting seldom gives trouble under conditions of absolute repose; if necessary a draught containing 10 minims of tincture of opium may be given half an hour before the dose of emetine. Slight nausea is not unwelcome as a proof that the drug is being absorbed. In a large number of cases it will prove impossible to bring about the complete disappearance of cysts, even by repeated courses of emetine, so long as the patient remains in a hot climate; under more temperate climatic conditions treatment can be resumed with more hopes of permanent success.

---

[1] The Treatment of Bacillary Dysentery was dealt with in THE LANCET last week.

In dealing with specially resistant forms a trial may be given to the method of combined administration of emetine with neosalvarsan or novarsenobillon; the dose of the arsenical preparation is 0·3 g. or 0·4 g. given intravenously once a week. This method has been employed in a number of cases by Brug and others, and favourable results are reported.

Enemata of quinine, in increasing strength from 1 in 5000 to 1 in 1000, have been largely used in the treatment of chronic relapsing cases, and are undoubtedly effective in destroying large numbers of the organisms which lie loose in the intestinal secretions or on the surface of the mucosa; it is, however, very unlikely that they are of any avail against cysts or amœbæ embedded in the substance of the mucous membrane; and though they may have their use as adjuvants, injections of quinine solution into the bowel must be regarded as ranking far below emetine in their parasitic-destroying properties. In giving any kind of enema, it is of the greatest importance to bear in mind the necessity for the utmost gentleness in manipulation in order to avoid the risk of perforation.

Acute Hepatitis.

The advent of acute hepatitis is indicated by pyrexia, with pain over the liver, which on examination is found to be enlarged and tender. A course of emetine in full doses should be inaugurated with the least possible delay, as there is reason for believing that by this means the condition may be brought under control and the formation of an abscess prevented. The onset of suppuration may be marked by no special symptoms: but more usually there are repeated rigors and a further rise of temperature, with a rapid deterioration in the general condition of the patient. The earliest local signs of hepatic abscess are often to be found at the right pulmonary base, and are due to the pressure effects of the abscess in an upward direction, causing partial collapse of the lung; with extension of the inflammatory process there may also be a pleural rub or signs of a pleural effusion. When there is reason for supposing that pus has formed, the diagnosis should be confirmed by an exploratory puncture and the pus then removed, either by an open operation or by aspiration. The contents of an amœbic abscess are usually completely free from pyogenic organisms, and hence, in the case of all but very large collections of pus, the method of aspiration is greatly to be preferred, on grounds both of simplicity and efficiency. A Potain's aspirator may conveniently be used, and after removal of the pus 4 or 5 gr. of emetine in solution should be injected into the abscess cavity.

Complications other than those connected with the liver are rare. Perforation may occur, and is occasionally the earliest manifestation of an amœbic infection which, up to the moment of rupture of the intestine, has been completely latent. An immediate laparotomy is indicated. More often perforation is a late event, and considerable difficulty in diagnosis may arise owing to the existence of adhesions and the circumscribed nature of the resulting inflammatory changes. The appropriate surgical treatment must be undertaken at the earliest moment.

EXPERIMENTAL CANCER RESEARCH.

FOURTH MEMORANDUM OF DEPARTMENTAL COMMITTEE OF MINISTRY OF HEALTH.

THE fourth[1] of the series of reviews summarising the present position of different cancer problems is concerned with the experimental work on cancer of the last 20 years under two main headings according as each contribution deals primarily with the properties of cells already cancerous or with the way in which cells become cancerous.

I.—THE PROPERTIES OF CELLS ALREADY CANCEROUS.

Transplantability of Animal Cancers.

The observation that cancer cells, when transported by natural agencies within the host, whether man or animal, settled down and continued to multiply in the secondary site led to the investigation of their behaviour when transferred artificially from one animal to another. Hanau (1889) and Morau (1891) were actually the earliest investigators to transplant tumours and obtain fresh growths from these grafts, but the importance of this method was first properly appreciated by Jensen (1902) and Borrel (1903). Their successes with mammary carcinoma (cancer) of the mouse were soon repeated by many others. The important features of this work were the strict limitation to animals of the same species as that providing the primary growth if continuous propagation was to succeed, and the permanence of histological type, rate of growth, and percentage of success, throughout long series of experiments. This showed that the malignant character was inherent in the cancer cells which alone survive transference to the new host. (The only exceptions to this rule of failure in the absence of living cells in the inoculum is formed by the sarcomata of fowls first studied by Rous and later by Fujinami. They are a group apart and will be dealt with in the final paragraphs of this memorandum.) These successful transplantations to normal animals show that it is unnecessary to invoke the hypothesis of an alteration in metabolism (see later section) to explain the continued growth of a cancer; the seed rather than the soil is the factor of primary importance. They do not, however, exclude the possibility of a local metabolic alteration being responsible for the transition of a normal into a cancerous cell.

Immunity or Resistance to Transplantation.

The fact that of ten children born, nine die from causes other than cancer suggested that the majority of persons possessed an attribute somewhat similar in nature to that of resistance to infection by ordinary infectious or bacterial disease, a natural immunity, and experiments were planned to elucidate this, using the method of transplantation, or grafting as it is sometimes called. It was soon found that animals once unsuccessfully inoculated were resistant to a second inoculation, even of considerably more active material, but it was also found that the resistant state could be set up by a preliminary treatment with normal tissues (blood, skin of embryo) provided that intact living cells were used. Killed cells were inactive. The resistant state was only effective against subsequent grafting and had no effect on established tumours. Still more disconcerting was the fact that even the most energetic methods of immunisation had no influence on the progress of primary cancer, as shown by recurrence at the primary site after surgical removal, by the occurrence of growths in secondary sites and by successful grafting of the original tumour in another part of the same animal; these, the most reliable tests of the malignant nature of the growth, were unaffected. This explains the failure of the methods of immunisation (artificial production of resistance) based on the results of grafting of transplantable tumours as a treatment for cancer in man, to which the primary cancers of animals present the closest similarity. None of the hypotheses framed to explain transplanted tumour resistance is entirely satisfactory, and its nature is still obscure.

---

[1] Cancer—iv. Circular 516. Ministry of Health. 1924. H.M. Stationery Office. 1d. The three preceding pamphlets were dealt with in THE LANCET, 1923, ii., 479; 1924, i., 770 and 1074.

Cancer Metabolism.

Metabolism, the word used to indicate the series of bio-chemical changes taking place in a living organism in the process of absorption and utilisation of the materials (food, drink, &c.) necessary to its existence, is more active during the period of growth than at other periods. Normal growth being, in essence, due to an orderly multiplication of the cells composing the organism, and cancer being a disorderly growth of some of the cells of the organism, it was hoped that by instituting a comparison between the metabolic processes in normal and cancerous animals some light might be thrown upon the forces at work in the production of cancerous tissue. Much effort has been expended in attempts to discover differences in the energy intake and output of cancer cells by studying the excretions of animals bearing transplanted tumours of such a size that they form a considerable fraction of the total weight of host and tumour together. No constant significant differences have been discovered.

Recently, working on the analogy of the method for the separation of nearly-related bacterial species by their action on various sugars and allied substances, slight but constant differences have been observed between normal and cancerous tissues outside the body. The water content of cancerous tissues has been found to be greater than that of normal tissues and as in growing young individuals, the more rapidly growing tumours are found to have a higher proportion of water. By the methods of gross chemical analysis and by micro-chemical tests malignant growths are found to have a higher proportion of potassium salts and a lower calcium content than the corresponding normal tissues. This feature also is shared by young and embryonic tissues and is therefore not really distinctive.

Vitamin and other Deficiencies and Cancer.

The growth of an animal is thought to be dependent on two factors: (*a*) an internal one, the growth impulse; and (*b*) an external one, the most important constituent of which is food supply.

Among the components of the food supply essential for normal growth are substances known as accessory food factors or vitamins, substances whose chemical nature is not exactly known but which are characterised by the smallness of the amount in which they are consumed proportionately to the effects produced by them. At least three of these vitamins have so far been distinguished and provisionally named, A, B, and C, but probably others exist. Total absence from the diet of one or other of these substances may lead to the occurrence of such diseases as scurvy, rickets, beri-beri (a disease affecting nerve tissues), &c.; relative absence leads to faulty nutrition, some effects of which are imperfectly understood.

The vitamins occur most commonly in green leaves but also in many other foods, and it is probable that any ordinarily varied diet contains an amount sufficient to promote normal growth and development.

Vitamin A (fat-soluble) and vitamin B (water-soluble) are the only accessory food substances which have been studied experimentally in relation to cancer. Neither deficiency, even when pushed to a dangerous degree, appears to exert any marked influence in retarding the growth of transplanted tumours in rats, nor does the presence of a tumour accelerate the onset of the symptoms of these deficiencies. Tryptophane deficiency (produced by making maize meal the only source of protein in the diet) leads to severe and fatal illness in mice and rats. Transplanted tumours grow in animals on this diet, the onset of symptoms and the fatal issue being hastened by the fact that the growing tumour causes more rapid exhaustion of this essential amino-acid.

Results of Tissue Culture outside the Body.

One of the methods used to investigate the process of growth is that known as tissue culture, in which by a specialised technique similar in nature to that used for the cultivation of micro-organisms, and which in essence consists in keeping fragments of tissue in a nutrient medium at a suitable temperature, the multiplication of the cells and the consequent growth of the tissue can be observed.

Burrows, Carrel, Lambert and Hanes and others applied the method of tissue culture to the study of cancer soon after the introduction of the method by Ross Harrison. The first remarkable fact which emerged was that while it was easy to obtain growth of tumours "in vitro" its continuance was much more precarious than in the case of normal tissues. The initiation of artificial culture was the difficulty with the latter. This curious antithesis to the phenomena of propagation in the living animal has only recently been cleared up. It is now known that tumours rapidly produce "in vitro" substances poisonous to themselves, and frequent replacement of the culture medium is necessary if growth is to continue. The toxic substances are innocuous to the growth of normal tissues. With proper precautions, therefore, there is no distinctive limitation to the growth of normal and cancerous tissues "in vitro"; both can apparently grow indefinitely with undiminished speed. The most essential of these conditions for growth is the supply of substances present in watery extracts of embryos of nearly allied species, for without them growth soon comes to a stop.

Embryonic tissues and tumours proliferate immediately on being planted out in a suitable medium, but adult tissues only begin to grow after an initial delay. It has now been shown that this initial period of delay can be cut out by adding to the culture medium the autolysate of normal damaged tissue, that is the fluid resulting from keeping the tissue in a saline medium at body temperature for a limited period. Rapidly growing transplantable tumours extracted in the cold (*i.e.*, without autolysis) give an extract with the same properties. This observation thus brings the malignant new growths into close relation with the processes of repair of tissues following upon injury. It may even provide a method of distinguishing true new growths from rapidly growing tumours due to other causes such as tuberculosis, syphilis, etc.

II.—THE EXPERIMENTAL STUDY OF THE CHANGES BY WHICH CELLS BECOME CANCEROUS.

The work in this direction can be conveniently summarised according to the underlying conceptions on which the various experiments have been based. They fall easily into two groups:—

1.—(*a*) The hypothesis of a microbic origin, in which it was supposed that cancer was due to invasion by a parasitic micro-organism and was therefore of an infective nature.

(*b*) The embryonic hypothesis, in which the conception was that during fœtal life small islands of cells became isolated from their parent tissue and in later life took on an independent form of growth.

(*c*) The gametic hypothesis which, arguing from a pretended resemblance between the method of division of cancer cells and that of the germ cells (which differs from that of all other normal tissues), supposed that cancerous growth depended on the cancer cells having reverted to the type of division peculiar to the sexual cells.

None of the experiments inspired by these hypotheses has led to the production of a new growth of more than a temporary character.

2.—The conception of Virchow that chronic irritation was of great causative importance in the production of cancer.

This latter group is the only one which has positive results to record and the remainder of this summary will be devoted to it. The results achieved will be most conveniently discussed under the headings of the various kinds of irritant employed.

Radiant Energy.

While the skin carcinomata due to intense insolation are well known in man, the only example of experimental production of new growth by radiant energy was the production of sarcomata in rats by X-rays, repeated exposure over about a year being necessary. Recently Bloch has succeeded in producing carcinoma of the rabbit's ear by the same agency after a still longer interval. No such success has followed long-continued repeated exposure to radium, and it is therefore impossible to say whether failure is due to unsuitability of the animals used or to unsuitable dosage.

Animal Parasites.

Occasionally in man, especially in some tropical countries, examples of carcinoma of the bladder are met with supervening on a chronic ulcerative condition due to infection by the eggs of a parasitic worm, *Schistosoma hæmatobium*. Parallel with this two forms of malignant new growth in the rat have been found to be constantly associated with the presence of animal parasites. These parasites are the *Gongylonema neoplasticum* occurring in the stomach of rats (Fibiger) and leading to epithelial overgrowth and carcinoma of the œsophageal end of the stomach. The other parasite is the cystic stage of a tape-worm, *Tænia crassicollis*, in the liver, which frequently sets up sarcomatous growth in the cyst walls.

The intermediate host of the *Gongylonema* (a nematode or round worm) is the American cockroach and these can be infected experimentally by feeding with the fæces of infected rats. Rats in turn are infected by allowing them to eat infected cockroaches. The larvæ encysted in the muscles of the cockroaches are set free in the stomach of the rat. They burrow in the epithelium lining of the stomach and in a certain proportion, which varies with the race of rats employed, carcinoma develops.

The definitive host of *Tænia crassicollis* is the cat, and rats are infected by contaminating their food with the fæces of infected cats. Sarcoma develops in about 50 per cent. of the rats successfully infected. Although cysts in the liver of the rat are usually multiple the sarcomata are usually solitary. The age of the animals does not seem to be of importance in either of these sets of experiments, young animals giving as high percentages of new growth as do old ones. Mechanical irritation by foreign bodies cannot replace these parasites as cancer-producing agents, nor does repeated injection of dried parasites or of extracts of them produce new growth. It is therefore believed that the long-continued application of substances excreted by the parasites is responsible for the result. This conception ranges these experiments along with those in the next group.

Chemical Irritants.

Carcinoma of the bladder has been repeatedly observed in aniline dye workers and the inhalation of minute quantities of aniline vapour has been incriminated, but so far the condition has not been reproduced in animals. Success has attended the experiments made with gas tar, however, and also with extracts of soot. The first experiments were conducted on the ears of rabbits by Yamagiwa and Ichikawa, but the real advantages of the method were only revealed when Tsutsui, and later Fibiger and Bang, turned to the mouse, which has proved to be the material of choice for such experiments. As a matter of fact the rabbit is not a very suitable animal and the rat and guinea-pig have proved to be extremely refractory. Here, again, long-continued repeated applications are necessary, sometimes extending for months, two or three times a week. The area painted need not be large, and the age of the animals has little influence; certainly old animals are not more suitable than young ones. All animals are not equally susceptible, and while simple tarring may initiate true skin cancer in three or four months in a few mice out of a large number, in the majority six to nine months is necessary and in some animals (again few in number) no result may be obtained although tarring be continued for 18 months. It has been found that if tarring be discontinued after three to four months, the subsequent development of cancer takes place in much the same proportion of animals and after about the same lapse of time as in control series painted continuously. This latent period may be shortened if another form of injury—namely, scarification—be combined with tarring (Deelman). (Cf. the association of cancer of the tongue in man with rough tooth stumps, smoking, and syphilis).

Similar successful experiments have been carried out with unrefined paraffin oil and with arsenic in the form of arsenious acid. In all, the new growths arise at the site of application of the irritant. The origin of cancer at the site of local irritation thus receives final confirmation and the experiments demonstrate the importance of the chronicity and specific character of the irritants which are effective. Many attempts have been made to identify chemically the substance in tar which produces cancer, but beyond determining its presence in the fraction boiling at 300°—350° C. without success. It is unlikely that a single chemical constituent is responsible, and so far the only success with a pure substance has been that recorded above for arsenious acid.

An interesting variant in these experiments is the production of sarcoma in mice and rats by repeated subcutaneous inoculation of tar. This is of importance as showing that the refractoriness of rats to tar painting only holds for the covering epithelium and not for connective tissues which in the rat are much more frequently the site of new growths. Examples occur in the sarcomata due to animal parasites already mentioned.

Up to the present it has not been possible to induce carcinoma in animals which have already developed cancer either from application of tar or spontaneously. This seems to indicate that although cancer arises as a local process, systemic generalised changes accompany its development. The nature of these changes is quite obscure.

What are the Infective Sarcomata of Rous?

It is very remarkable that the infective sarcomata of the domestic fowl discovered by P. Rous, although providing the only positive examples of new growths transmissible without the intervention of intact cells, should have been so infrequently called on to support the arguments of those who favour the hypothesis of a microbic origin of malignant new growths.

These tumours, of which five or six strains are now in existence, all have the structure and biology of sarcomata although differing in histological details.

They all grow rapidly, infiltrate the muscles of the trunk and limbs and disseminate widely to the lungs and other internal organs. Glandular metastases are not a prominent feature of their progress. They can readily be transmitted to normal fowls by inoculation of tumour fragments under the skin, but with some of them, and notably the first strain isolated by Rous, only the original race of fowl (Plymouth Rock) was at first susceptible. It now grows nearly as well in several other races, especially in young birds. The distinguishing feature of these tumours is the fact that cell-free filtrates can also transmit the disease and the active principle withstands drying, the action of glycerine, and heating to 45° C. for half an hour. Each of these procedures destroys the vitality of all the transplantable tumours of the mouse and rat so far studied. The active agent behaves thus far like an ultramicroscopic virus, but it has not yet been possible to produce the disease with artificial cultures of it. The elucidation of the relation of this series of infective tumours to the other malignant new growths of birds and mammals depends on the solution of an extremely delicate problem—viz., Do the cells of these tumours when freed from the virus still behave as malignant new growths when introduced into the bodies of susceptible animals or do they behave as normal cells? If they behave as sarcomata then the virus has the property of inducing the change from normal to malignant cell with great rapidity and certainty. If they do not, then these tumours are in reality of the nature of granulomata, depending for their continued proliferation on the persistence and multiplication of the infecting organism.

BUCHAREST.

(From our own Correspondent.)

Effects of Facial Anomalies.

In addition to anomalies in different parts of the body which may exhibit a tendency to be far reaching in their effects, Dr. V. Molnár describes a class of case where a primary deep-seated anomaly of the face, and especially of the base of the skull, may lead to marked changes in the four extremities. He has had an opportunity of observing a series of such cases where the cranial anomalies were principally marked by early ossification and sclerosis of the base of the skull. The changes were usually seen in all four extremities, although they were most marked in the upper limbs. They may be manifested in three ways: (1) by the absence of a toe or finger, or as a general shortening of the limb; (2) by an increase in the number of fingers or toes, or a general increase in the size of the limb; (3) by a change which includes a partial excess and defect, such as an increase in the number of metatarsal bones, with amalgamation of either fingers or toes, and increase or decrease in the length of the extremities, as described by Prof. Babes. A remarkable fact about these phenomena is the symmetrical arrangement of the deformities as well as their resemblance to certain animal groups, the artiodactylates, and the perissodactylates. Dr. Molnar details a number of cases to illustrate his observations and believes that there is a region of the skull which stands in close relation to the development of the extremities. In other words, that a centre must be assumed to be in this region which determines the normal development of the extremities, and any change in shape or character of the former will result in an abnormal growth of the limbs. A further knowledge of this process may aid in clearing up some of the mysterious factors which underlie the differentiation of the various races and classes of animals.

Chronic Alcoholism in Roumanian Hospitals.

At a Roumanian Medical Congress held recently in Fimisoara, a report was read by Dr. Hatzuganu on the incidence of chronic alcoholism in several large hospitals of Roumania, with particular reference to Transylvania. During the past 15 years some 1950 cases of alcoholism were treated in the hospitals under his control, and of that number 60 per cent. were between 30 and 49 years of age. He made a careful study of 70 cases, and found that as a rule male alcoholics live longer than female. The autopsies frequently showed heart lesions in the form of brown atrophy and fatty degeneration. In the lungs œdema and congestion were most often seen. In the liver fatty degeneration was found in about 60 per cent. of the cases. Cirrhosis was frequent, though it is interesting that this condition has never been produced experimentally in animals. In no case was the liver normal. Chronic fibrosis was the commonest condition seen in the pancreas. The kidneys were never normal, chronic nephritis occurring in all but five patients, the parenchymatous variety being most frequent. In the stomach atrophic gastritis was found in many cases. The brain was almost always œdematous; acute and chronic meningitis occurred frequently, and atheromata of the cerebral vessels was not unusual. In his opinion the essential pathological processes caused by alcohol in the various organs of the body are hyperæmia, degenerations (particularly of the fatty kind), and connective tissue proliferation. The cases are often treated entirely for their nervous symptoms when the circulation needs treatment most. Symptoms vary markedly with idiosyncrasy and with the dilution of the alcohol used.

Skin Lesions caused by Mercury.

At a meeting of the Medical Society of Brasow, Dr. Saxlehner stated that he considered the most common mercurial eruption to be acne, such as occurs on the hairy part of the extremities in the form of nodular infiltrations of livid colour about a hair follicle. This condition, as well as various forms of transient dermatitis on the flexor surfaces of joints, is only induced by the external application of the drug. Eruptions after internal use may be of manifold character, varying from an erythema without desquamation or subjective symptoms to severe vesiculation and pustulation with involvement of nails, hair, and the mucous membranes, together with such severe constitutional disturbances that a general disease may be suspected. Thus measles, scarlet fever, erysipelas, hæmorrhagic purpura, multiform exudative erythema, and acute eczema may be simulated. The diazo-reaction may be positive.

The appearance of an eruption is independent of the combination of the drug employed and of the technique. There is nothing typical about form grouping and distribution of the lesions, but the peculiar violet colour, extensive desquamation, and the rapid disappearance after the drug is stopped are often typical. If the drug is introduced anew, the diagnosis can often be made by observing an exacerbation. In some cases mercury can be detected in the urine and the fæces. Idiosyncrasy plays an important rôle, but it is more an idiosyncrasy of organs than individuals, for in some the skin is readily affected, in others the internal organs, and in others again the nervous system. Patients who react readily by salivation and rise of temperature must be classed among the latter. Strangely enough, the organs in which mercury is usually deposited are not the same as those affected by idiosyncrasy. The same organ will generally continue to react even where the method of application is changed. In conclusion, a peculiar local reaction in syphilis is mentioned which may be of diagnostic value. Twelve or 24 hours after an injection of salicylate of mercury a macular or maculo-papular luetic eruption will spread or become confluent, and the colour will become more violet.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Exclusion of Foreign Practitioners.

LAST month the State Board of Medical Examiners of Texas decided to refuse to allow candidates to sit for examinations for the State licence to practise medicine until they had taken out their first papers for naturalisation. Twelve other States have already adopted similar regulations, many of them requiring full naturalisation and thus five years residence in America. The recent influx of foreign physicians into this country is raising the question of imposing similar restrictions in several other States.

Small-pox in Michigan.

During the first half of this year there have been 3999 cases of small-pox with 133 deaths in the State of Michigan. Of these totals the city of Detroit accounts for 1532 cases and no less than 106 deaths. The severity and virulence of the epidemic have been such in this city that even Christian Scientists have come to be vaccinated, and outside of the city it is estimated that a quarter of a million people were vaccinated in the last three weeks of June. There has been some overflow of contagion into Canada on the north and into Ohio to the south, but at the present time the epidemic would seem to be coming under control. It will have served to remind some of our antivaccinators that small-pox is not yet a matter of historical interest only, belonging, as they would have us believe, to a period when sewers were not invented.

The Ætiology of Scarlet Fever.

One of the most interesting papers presented at the recent meeting of the American Medical Association[1] was that of Drs. George F. and Gladys Henry Dick describing their research into the immunology and ætiology of scarlet fever. They recovered two culturally distinct strains of hæmolytic streptococci from the throats of scarlet fever patients and in one case from the infected finger of a nurse who had been attending a case of scarlet fever. One of these strains ferments mannite; the other does not. The Drs. Dick were able to produce experimental scarlet fever in human volunteers from both strains. They showed, however, that the power of agglutination of the immune sera was confined to homologous strains, thus refuting the contention of Tunnicliff and Dochez that the agglutination test may be used for the identification of scarlet fever streptococci. The toxin produced by these streptococci gives a typical reaction—malaise, nausea, vomiting, fever, and a scarlatinal rash appearing in susceptible persons a few hours after injection of the toxin and passing off in 48 hours. By commencing with minimal doses an immunity can be built up as shown by experiment on exposed individuals and by the skin test. The great difficulty in adopting this discovery to the requirements of preventive medicine at the present time is the absence of any method of standardising the toxin. In spite of this difficulty Dr. Abraham Zingher, of Schick test fame, has tested over 7000 school-children in New York for susceptibility to scarlet fever and found 8 per cent. positive and 60 per cent. pseudo-reactors. In a private co-educational school he found no less than 83 per cent. of the children to be susceptible. Dr. Zingher used a dilution of 1 in 1000 of crude toxin, but his figures must clearly be accepted with reserve until the toxin can be measured in some kind of minimal lethal dose.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

(Continued from p. 246.)

SECTION OF MEDICINE.

WEDNESDAY, JULY 23RD.

ON the first day of this section, Prof. A. J. HALL (Sheffield), the President, being in the chair, Dr. T. WARDROP GRIFFITH (Leeds) opened a discussion on

Cardiac Irregularities,

especially in relation to prognosis and treatment. He expressed his admiration for the work of the older observers who had long ago classified cardiac irregularities into those of time and force, and noted that the two were frequently combined. The irregularity produced by the missing of one beat in an otherwise regular series they termed an "intermission"; and they appreciated the fact that such an intermission might be due to a true intermission of cardiac action or to a weak beat not appearing at the wrist. He thought that in thus contrasting irregularity with intermission the older writers were expressing the difference between the arrhythmia that is now known as auricular fibrillation, and that dropping of the heart-beat which is usually the expression of an extrasystole. It was impossible to over-estimate the importance of the work of Sir James Mackenzie and Sir Thomas Lewis, whose experimental work and clinical observation had greatly raised the prestige of British scientific medicine.

Dr. Griffith classified cardiac irregularities into six main groups, according to their method of production: 1. Sinus arrhythmias. 2. From extrasystoles: (*a*) single, (*b*) double, (*c*) paroxysmal tachycardia. 3. From alternans. 4. A-V heart-block. 5. From sino-auricular block. 6. From fibrillation and flutter. Everybody was familiar with the very common form of irregularity associated with auricular fibrillation; it was present in over 50 per cent. of all patients admitted to hospital for cardiac failure. He traced the history of the growth of our knowledge of this subject from the original observation of James Mackenzie that complete arrhythmia was associated with that form of venous pulse which at that time he called "ventricular" down to Lewis's convincing electrocardiographic results. It was now known that the presence of a pulse which had no recognisable rhythm meant the presence of auricular fibrillation. In this condition hundreds of stimuli were showered by the auricle upon the auriculo-ventricular bridge; only a few of them, however, were able to cross the bridge, the ventricle responding, on "the all or nothing" theory, with the fullest efforts of which it was capable at the moment the stimulus was received. This resulted in contractions of varying force at irregular intervals. The development of auricular fibrillation was very variable, and it was certain that it was often of an abiding nature in cases where there was nothing to suggest the actual date of onset. The majority of patients soon complained of dyspnœa, with the usual symptoms of cardiac failure, but some were able to continue their ordinary life, and in them the condition was only detected when for some other reason a routine examination was made. It had been recognised for many years that the form of cardiac failure associated with a cardiac action devoid of rhythm called for the free use of digitalis; and it was now known that this beneficial action was due to the influence of digitalis in depressing the conductivity of the functional tissues which was especially developed in cases of auricular fibrillation. The number of stimuli reaching the ventricle was decreased; the ventricles, therefore, had a longer time in which to recover, and responded with stronger beats.

Opinions differed as to whether the action of digitalis was limited to this effect on the functional tissues or whether there was also some direct action on the muscle of the ventricle: as a result of clinical experience Dr. Griffith was himself strongly of the opinion that some such direct action must exist. The drug must be given in adequate doses; he gave 10 minims of the tincture every four hours or oftener; but he had had very little experience of the Eggleston method of massive doses. Complete heart-block might be produced without harm in some cases, but this result was not devoid of danger and should be avoided. If extrasystoles occurred as the heart-beat slowed it should be taken as a strong hint to stop the drug, but he did not go so far as Lewis and make it a universal rule to omit the digitalis in such conditions. Digitalis, however, did not cause the fibrillation to cease, and the pulse remained non-rhythmical; quinidine, on the other hand, did in some cases at least restore the normal rhythm, and the investigations made with this drug had further increased our understanding of this condition. Dr. Griffith confessed himself entirely convinced by Lewis's experimental proof of the theory of the "circus movement," according to which there was a continuous wave of contraction passing round a tract of auricular muscle, always with a short portion of responsive muscle between the advancing crest of the wave and its retiring tail. Quinidine had two actions: it lengthened the refractory period and also slowed conduction in the auricular musculature; and it was by a combination of these two actions that it abolished the circus movement and so restored the normal rhythm.

It remained to decide whether the restoration of normal rhythm was necessarily a desirable achievement. This depended on the answer to the questions: "What was the value of the restoration of the normal rhythm?" and "What were the dangers?" To restore normal rhythm would be to restore also the propelling power of the auricles and to equalise the amount of blood dealt with by the ventricles at each beat, both of them factors that must be desirable. The dangers could only be briefly noted, and amongst the most serious results that had been observed were nausea, vomiting, giddiness, palpitation, faintness, convulsions, syncope, respiratory difficulty, and other signs of heart failure; in some cases embolism had occurred. He would leave this matter to the meeting. It was well known that extrasystoles might arise in a number of different situations, the sino-auricular node, the auricular musculature, Tawara's node, the main bundle, and right or left ventricle. They could all be produced experimentally and detected by the electrocardiograph. It was reasonable to look upon extrasystoles as due to some irritable focus at their point of origin. In the case of the ventricles it frequently happened that an extrasystole fell after every normal systole, suggesting that the normal systole had supplied the stimulus for the discharge of the extrasystole that followed. Similarly, the first extrasystole might provide the stimulus for a second, and the second for a third; in this way the condition of paroxysmal tachycardia would soon be reached. It was of the utmost importance to recognise when a cardiac irregularity was due to extrasystoles, but occasionally it was impossible without instrumental methods. Irregularity from extrasystoles must be distinguished from sinus arrhythmia, flutter and fibrillation, and pulsus alternans. Prognosis would depend chiefly on the view taken of the conditions associated with the extrasystoles rather than on the actual irregularity. Pulsus alternans, in which every second beat was weak without the excuse of being premature, was an extremely grave sign, and when persistent provided strong evidence of myocardial degeneration.

Prof. **John Hay** (Liverpool) stated that prognosis and treatment both depended on the recognition of the type of irregularity present, and in his view there was nothing more important in the management of heart cases than the power to recognise the presence of auricular fibrillation. In fibrillation the normal rhythm was lost, the action of the ventricle was disorderly and chaotic, and the arrhythmia was aggravated by exercise. A rapid ventricular action was not an indispensable characteristic of fibrillation; even in the absence of treatment with digitalis it might be well within the normal limits. The common irregularities might be divided into two groups: (*a*) Sinus arrhythmia, the arrhythmia associated with respiration, and that due to premature beats. Other things being equal, the prognosis in this group was good. (*b*) Auricular fibrillation and the alternating pulse. With auricular fibrillation much distress, induced by the onset of fibrillation, a rapid ventricular rate, and a failure to respond to digitalis, were all of unfavourable import. The alternating pulse was admittedly an ominous sign, and he regarded the transitory alternation following an extrasystole much more seriously than did Dr. Wardrop Griffith. He had recently had the opportunity of pooling the results of several observers using quinidine; these were, briefly, that in 166 cases of fibrillation with valvular disease quinidine restored the normal rhythm for more than three months in 27·7 per cent. of cases. In cases of fibrillation without valvular disease the percentage of success was 40. Best results of all were obtained in Graves's disease, especially if the toxæmia was treated by partial thyroidectomy. The action of quinidine was also greatly increased if any septic focus was radically dealt with beforehand.

Dr. **W. J. Tyson** (Folkestone) recalled the position when the subject of prognosis in heart disease was discussed at the annual meeting in 1886, and explained the changes of views that had occurred since then. Although he did not use the polygraph and electrocardiograph he did not think that his patients had suffered thereby: but he freely admitted that by these means our knowledge of the classification and diagnosis of heart disease had been greatly advanced, although it was doubtful whether treatment had progressed to the same extent. In his view the greatest benefit conferred on patients by the work of Mackenzie and Lewis lay in the fact that it focused attention on the cardiac muscle rather than on the valvular disease. He deprecated the fashion of telling patients who suffered from no symptoms of heart disease that they were the victims of some cardiac irregularity.

Dr. **M. G. Foster** (Harrogate) said that the irregularities of youth and extrasystoles were not now viewed very seriously, but he was pessimistic over auricular fibrillation when the damage was already done at the onset of fibrillation, and he urged the need of further research to discover the cause of fibrillation.

Dr. **Halls Dally** (London) disagreed with the pessimistic view just expressed about auricular fibrillation; the more his experience increased the less gloomy became his view, and he knew of many patients who lived active and useful lives for many years. Digitalis was frequently given in dosage inadequate to secure a state of partial heart-block, or was not persisted with for sufficient periods. Quinidine achieved most success in chronic cases, and should be avoided in acute cases with rapid onset.

Dr. **G. J. Langley** (Manchester) considered that the most common cause of irregularity was produced by ventricular extrasystoles, which he divided into two groups, the commonest being physiological, associated with slow pulse-rate and removed by exercise; the second group was unaffected by exercise and indicated myocardial disease. He suggested that insufficient attention was paid to the inconvenience lengthy methods of treatment caused the patient, and advocated the massive dosage of digitalis as suggested by Eggleston, followed by quinidine for cases of auricular fibrillation.

Thursday, July 24th.

On the second day, Dr. **W. Langdon Brown**, Vice-President, being in the chair, a discussion on

Jaundice

was opened by Dr. **J. W. McNee** (London), who said that he desired to deal more particularly with the application of the new advances that had been made in the study of jaundice to medicine and surgery. As landmarks in the modern literature of icterus he chose first Wickham Legg's book published in 1880; next, the experimental work of William Hunter on the relation of the spleen to blood destruction, and of blood destruction to jaundice; and, lastly, Sir Humphry Rolleston's book published in 1912. The work which in recent years had had most influence in developing our knowledge of jaundice was then outlined, one of the most important developments being the work of Prof. Hijmans van den Bergh, who had discovered a method by which bilirubin could be detected and measured quantitatively in small amounts of albuminous fluids such as blood serum. Moreover, by this method it was possible to detect qualitative differences in the bilirubin present in the blood serum in different forms of jaundice. By means of this reaction a fundamental change in our conception of jaundice had been produced, and attention had been turned from the colour of the skin and mucous membranes to what was occurring in the blood.

The term "reticulo-endothelial system" was of recent origin, and had been applied by Aschoff to a system of endothelial cells scattered widely throughout the body, but having very specialised activities in certain situations. The cells which were of chief interest in the consideration of jaundice were the endothelial cells lining the sinuses of the spleen, and the endothelial cells of von Kupfer along the venous capillaries in the liver. The experimental production of icterus in birds by McNee seemed to show that in these animals the cells concerned in the breaking down of hæmoglobin and elaboration of bile pigment were the Kupfer cells of the liver and the reticulo-endothelial cells of the spleen, and not the polygonal cells of the liver. In birds the spleen was very poorly developed, and the Kupfer cells in the liver were very numerous; and if the liver was extirpated no real icterus followed. This work suggested a reconsideration of the whole problem, and the view that it was the reticulo-endothelial cells which were concerned in the production of icterus by hæmolysis was confirmed by Lepebne and others. Important experiments on dogs, in which only a "head and thorax" circulation remained, were carried out by Whipple and Hooper, and repeated by Rich, and McNee and Prusfk, but the results were somewhat contradictory, so that the experimental proof for a true hæmolytic icterus occurring apart from the liver could not yet be accepted as complete. The best evidence of a clinical nature was the appearance of bilirubin in hæmorrhagic effusions in the various body cavities, in which it seemed certain that the liver could take no part. It had, however, to be admitted that in such cases no general icterus ever occurred.

The view that jaundice might arise from disordered function of the glandular cells of the liver had been developed chiefly by the French school, and this explanation inferred that if bilirubin was elaborated by the reticulo-endothelial cells, the polygonal cells must be healthy in order to pass it on to the bile capillaries. On the view that it is the cells of the reticulo-endothelial system which elaborate bile pigment, and that the polygonal cells pass it on to the bile capillaries, a new theory of jaundice had been put forward; and to explain the two varieties of bilirubin, giving the "direct" and "indirect" van den Bergh reaction, it had been suggested that the bilirubin was modified in some way in passing through the glandular cells.

On this theory jaundice might be produced in four different ways: (1) When bile pigment was formed in the cells of the reticulo-endothelial system and passed on to the bile capillaries, but was then obstructed; this was the case in obstructive jaundice, and the van den Bergh test gave a prompt direct reaction. (2) Where the bile pigment was formed by the reticulo-endothelial system, but where it was not passed on to the bile capillaries owing to damage to the polygonal cells; the bilirubin then passed direct into the general circulation by the hepatic venous radicles. This occurred in toxic and infective hepatic jaundice, the van den Bergh test giving a biphasic reaction. (3) Where too much bilirubin was formed by the reticulo-endothelial system for the polygonal cells to deal with adequately and the excess naturally passed straight into the hepatic vein. Such was the condition in hæmolytic jaundice, and the van den Bergh test gave a delayed or negative reaction. (4) Where there was both damage to the polygonal cells and obstruction in the bile-ducts. Here some bilirubin would pass direct to the hepatic vein, some would be passed on to the obstructed bile capillaries and be there reabsorbed. This would produce a combined form of icterus with variable van den Bergh reactions, such as occurred in catarrhal jaundice. Dr. McNee then suggested that the most suitable classification of jaundice at present was one arrived at on these lines: (1) Obstructive hepatic jaundice; (2) toxic and infective hepatic jaundice; (3) hæmolytic jaundice.

The clinical use of the van den Bergh test enabled the progress of an attack of jaundice to be traced; it had shown that the colour of the skin was no guide to the amount of bilirubin in the blood; further, it had revealed the condition of "latent icterus," and many diseases, notably pernicious anæmia, which had not previously been considered in the light of their icteric nature, had been brought into the group of latent hæmolytic jaundice. It gave extremely useful information during treatment with salvarsan, and made it possible to distinguish between obstructive and hæmolytic jaundice.

Prof. HIJMANS VAN DEN BERGH (Utrecht) reminded the meeting that it was Dr. McNee who had first suggested the probability that it was the cells of the reticulo-endothelial system that elaborated bile pigment, and by so doing had turned our thoughts on the production of jaundice in a new direction. He knew of no clinical observations that would not agree with Dr. McNee's theory, and it agreed entirely with his own investigations. He agreed that it was impossible to prove the existence of a true hæmolytic jaundice experimentally, and so far as animal experiments went it must be remembered that animals differed greatly from one another and from man as regards liver function. In all experiments on dogs it should be kept in mind that their kidney threshold for bilirubin was extremely low. With regard to the formation of bilirubin in hæmorrhagic effusion, the diazo-reaction allowed the process to be studied quantitatively, and they had found that the bilirubin content of the effusion was incomparably higher than that of the blood. The doubt as to whether this pigment was truly identical with bilirubin had been completely dispelled by the work of H. Fischer. The explanation why these effusions were not accompanied by jaundice might well be that no absorption took place, or possibly it might be due to some obscure difference between the pigments with the direct and indirect reaction. With regard to the diazo-reaction, Prof. van den Bergh emphasised that he did not consider the quantitative method a very perfect one, but on the whole he thought that the original method gave more satisfactory results than any later modification. There were, however, occasions when he found some of the other methods helpful. Hæmatin, methæmoglobin, and bilirubin might all be found in the blood together, and in these cases some chemical test was essential. Care must also be taken to distinguish icterus from the yellow colour due to luteinæmia. Lutein, which was sometimes absorbed in quantity by people who eat freely of green vegetables and eggs, had nothing to do with bilirubin. After describing some of the conditions in which he had found the test of value, Prof. van den Bergh concluded by discussing briefly the two varieties of bilirubin. There certainly existed the two varieties, but the nature of the difference was unknown. It was true that one form was usually found in obstructive jaundice and the other in hæmolytic jaundice, but exceptions to this rule occurred which it was as yet impossible to explain.

Sir WILLIAM WILLCOX (London) said that there would be general agreement with Dr. McNee's classification of jaundice. It would be agreed by most people that a hæmolytic jaundice did occur, although it was relatively uncommon chemically; but the evidence for it from animal experiments was by no means convincing. He thought that by far the best evidence was to be found on the clinical side. Toxic and infective hepatic jaundice was, in his view, by far the most important type and the commonest. Jaundice of this type might be produced by poison, chemical, bacterial, or protozoal, or by auto-intoxication. The explanation of this type of jaundice was to be found in a consideration of the function of the liver which had been insufficiently recognised—the "toxiphylactic" function of the liver. The liver was the main protective organ of the body from poisons of all kinds, and in doing its duty in this direction was often irreparably damaged; the passage of bile into the bile capillaries was interfered with and jaundice resulted. The depth of jaundice was no measure either of the severity of the toxic action or of the degree of hepatic deficiency. Sir William Willcox drew attention to the variations that were found in the times that elapsed between the toxic action on the liver and the onset of jaundice. He stated that in catarrhal jaundice the lævulose test always gave evidence of impairment of hepatic function, and he was sure that the view of the French school was correct—viz., that catarrhal jaundice was a liver-cell degeneration set up by an intestinal bacterial infection.

Dr. LANGDON BROWN said that the old conception of hæmatogenous jaundice was returning in the new guise of hæmolytic jaundice. He thought the correctness of the French view of catarrhal jaundice had come out clearly, and he instanced cases of this disease in which the van den Bergh reaction was mainly indirect, while hepatic insufficiency was proved by the lævulose and lipase tests. Dr. McNee's work explained why splenic anæmia might arise from different diseases of the spleen, and it threw much light on latent jaundice.

Dr. PLATT brought forward some observations suggesting that in acholuric jaundice the red cells might actually develop an increased resistance to hæmolysis.

Mr. R. H. PARAMORE (Rugby) discussed the relationship of the blood flow through the hepatic capillaries with the rise of toxic jaundice, referring especially to the jaundice that is sometimes seen in the so-called toxæmias of pregnancy.

FRIDAY, JULY 25TH.

On the third day Prof. F. W. EURICH (Bradford), Vice-President, being in the chair, Dr. W. MCCONNEL WANKLYN opened a discussion on

Small-pox,

with especial reference to diagnosis. He dealt first of all with small-pox in its general bearing, and said that the essential thing in any such consideration was to surround oneself with the psychological atmosphere of small-pox, and he did not intend to delay in order to discuss the two main types of the disease and the clinical or pathological phenomena which distinguished them. Small-pox was not a beautiful scientific specimen to be cherished, it was a poisonous and devilish enemy to be put utterly to the sword. Small-pox had been protected, and was still being protected, in this country by misunderstanding and misrepresentation; it was one of the duties of the medical profession to tear down this cloak and expose the nakedness and foulness of the mischief behind it. Once small-pox was so displayed it would have short shrift.

Dr. Wanklyn then showed curves contrasting the percentage of London infant vaccinations with the percentage of freedom from small-pox in London. The striking feature of the curves was that whereas the percentage of infant vaccinations had fallen steadily since 1904 to less than 45 per cent. in 1921, yet the percentage of freedom from small-pox was higher than ever, and had been at a constantly high level for the past 20 years. This was not due to any diminution in the virulence of small-pox, or to any general decrease in its incidence. Small-pox in other parts of the world was still highly virulent, and competent observers estimated that there were at least one million cases of small-pox in the world every year. No explanation could be found in improved sanitation. He could state with authority and intimate knowledge that the one factor which had pulled small-pox down and which was now holding it down was the team-work of the profession and the voluntary civic spirit of its members. Small-pox abounded in the world at large, and it was as dangerous as ever to the people of these islands, whose decreasing use of vaccination had made them individually almost defenceless to small-pox, and had greatly increased the general risk. It had been countered only by the continued shepherding efforts of the medical officers and their colleagues, but for whose efforts small-pox would sweep again across these islands as calamitously as ever. The clearance of small-pox was a civic task that members of the medical profession must undertake in their capacity as citizens; they were not only citizens, but citizens with special knowledge whose duty it was to lead the way.

The one supreme weapon for holding small-pox was accurate diagnosis. Diagnosis might be said to be the discarding of the unimportant and concentration on the essential features of the case; and the first question on which hung all the rest was "Can this be small-pox?" To answer this question one should recall in methodical series the different varieties and stages of the disease. If small-pox cannot be eliminated by this process a more careful investigation of the lesions must be undertaken. For this a thoroughly good light and a view of as much of the skin as possible were desirable. Too much attention must not be paid to the old text-book signs—shottiness, umbilication, uniloculation, cropping, the rash being in different stages, or on the soles of the feet, spots on the palate. These were not sufficiently distinctive. The four master cards were: (1) prostration, (2) distribution, (3) localisation, (4) maturation, and of these distribution was the soundest of all; its key was that the rash of small-pox favours the irritated and shuns the unirritated surfaces. Prostration was not an absolute sign, but a copious rash preceded by complete absence of prostration was a strong argument against small-pox.

Dr. C. KILLICK MILLARD (Leicester), whose paper was read in his absence, said he thoroughly agreed with all the opener had said about the importance of accurate diagnosis, and he thought that no student should be allowed to qualify without giving specific evidence that he was at least able to suspect small-pox when he saw a case. He also agreed as to the unreliability of the old text-book signs. He divided the body into (*a*) trunk, (*b*) limbs, ignoring the head and neck. If after a careful count the lesions were more numerous on the limbs, the case was certainly one of small-pox; whereas if they were more numerous on the trunk it was almost certainly chicken-pox. There was no other single test of equal value to this distribution test. With Dr. Wanklyn's remarks on the general aspect of small-pox he was by no means in such complete agreement. He was unable to foretell what the future had in store for Leicester, but he had always said that whenever small-pox visited Leicester it demonstrated unmistakably the power of vaccination to protect the individual; but it also demonstrated that the orthodox view as to the great value of infant vaccination in protecting the community was greatly over-estimated. Although he agreed with Dr. Wanklyn's lucid description as applied to Asiatic small-pox, he thought it was unfair to apply it to the American form. Alastrim small-pox was not a deadly or disfiguring disease, although it was undoubtedly true small-pox. He disagreed with Dr. Wanklyn's estimate of the cost to the community of dealing with an outbreak of small-pox, but he associated himself heartily with the plea to develop team-work so as to sweep the disease out of the country.

Dr. R. P. **Garrow** gave an account of the epidemic of mild small-pox prevalent at Chesterfield. The disease as it existed in Chesterfield differed strikingly in many ways from typical virulent small-pox. It was milder, less infective, and was controlled by a less degree of vaccination. It was not characterised by scaring, the rash was small in size and unilocular, and evolution was more rapid. The crust formed was not the typical crust of small-pox, because the lesions did not go on to real pustulation; it appeared rather as an agglomeration of golden grains, as if due to the drying up of a clear serum. So far as the Chesterfield epidemic was concerned, no cases of virulent small-pox had occurred.

Dr. E. H. **Snell** (Coventry) thought that the main difficulty caused by the present epidemic of mild cases was the administrative use of controlling it. The man in practice was met by cases which showed only a few pimples so negligible that the patient said nothing about them. There was nothing about the cases in the ordinary way to arouse suspicion of small-pox, and so they went unrecognised and continued to spread the disease.

Dr. J. A. **Watt** described the epidemic at Derby, which was very similar to that at Chesterfield.

Dr. **Eurich** read a paper on the *Clinical Features of Anthrax*, illustrated by lantern slides. He described the clinical appearances of the pulmonary and intestinal forms of the disease. In these forms the disease was so rapidly fatal that there was no time to undertake any laboratory investigations that might possibly prove helpful in establishing the diagnosis. He emphasised the fact that in cutaneous anthrax the diagnosis was bacteriological, and that microscopical examination for the anthrax bacillus should be made by the practitioner himself without delay. As regards treatment, he did not excise the pustule except in special cases; the part was kept absolutely at rest and Sclavo's serum injected, 80 c.cm. being given for the initial dose; a second dose of 60 c.cm. followed 18 hours later, with more injections later if needed.

Dr. F. C. **Eve** (Hull) read a paper on the *Domestic Estimation of Urinary Sugar*, describing a method by means of which patients can themselves measure the daily excretion of sugar. Every night the patient passes urine into a clean thermos flask. The specific gravity of the urine is taken and a lump of yeast is added to the urine. The flask is corked with cotton-wool. After fermentation the specific gravity is again taken, and will be reduced to an extent proportional to the amount of sugar originally present. The resulting specific gravities are charted daily in two curves, the closer the two curves approximate the less the sugar excreted.

SECTION OF OPHTHALMOLOGY.

WEDNESDAY, JULY 23RD.

The President of this section, Mr. A. **Maitland Ramsay** (Glasgow) referred to the loss which the section had recently sustained through the death of one of their vice-presidents, Mr. G. H. Oliver (Bradford). As Prof. **Ignacio Barraquer** (Barcelona) had been prevented from attending the meeting to open the discussion, the Secretary (Dr. J. D. McCulloch) read Dr. Barraquer's paper on

The Intracapsular Method of Cataract Extraction.

Dr. Barraquer in his paper described the classical operation by cystotomy as extraordinarily imperfect from a surgical point of view. It involved (1) making pressure on the eyeball: (2) retention in the eye of the greater part of the capsule and some of the cortex of the lens; and (3) the entrance of unnecessary instruments into the eye. The many methods of intracapsular extraction, devised by Daviel and others from 1745 onwards, fell into two groups (1) by traction and (2) by pressure. The traction methods of Kalt and Knapp were those most frequently adopted in the former class, but had never become popular. The instruments employed usually tore the capsule, and the operation became an ordinary cystotomy with all its inconveniences, aggravated by the complications caused by severe traction on the zonule. Smith's brilliant successes had demonstrated the great advantages of intracapsular extraction, but in other hands his operation had not met with equal success. Dr. Barraquer said that in 1916 he arrived at the idea of a pneumatic forceps (cup) that would grasp the lens by its anterior face, and without breaking its capsule, by stretching, would detach it from its attachments and pull it out entirely. Experience showed the advantage of rupturing the fibres of the zonule close to the lens instead of at their ciliary attachment. This he secured by giving a vibratory movement in the vacuum. The large iridectomy, done in the earlier cases, proved to be unnecessary; the adoption of the Hess peripheral iridectomy and the previous suturing of the conjunctival flap improved the operation; the paralysis of the orbicularis by injection of novocaine by Van Lint-Millard's technique was also adopted. Among the indispensable conditions for successful performance of his operation were the use of a perfect erisiphaque, well regulated beforehand with reference to the physical conditions of the cataract on which the operation was to be done, the avoidance of all pressure on the eyeball, and the preservation of the sphincter of the iris. In his own clinic, failure to secure a black, central, round pupil with S/10 vision was exceptional. The advantages of his operation were specially noteworthy in diabetic and myopic cases. Vitreous ruptures and iritis occurred less frequently than with the old operation. He said that he had practised cataract extraction by capsulotomy for 16 years, and by phaco-eresis for eight years, and during the latter period the percentage of patients with normal visual acuity was more than double that in the former period; and the number of operative accidents and post-operative complications had diminished in the same way. The technique was not difficult, though completely different from that of other operations. Recent statistics published by Dr. Basterra (Madrid), Saint-Martin (Toulouse), Guiral (Habana), Green (San Francisco), and others showed the success of the operation in other hands.

Technique of Operation with New Pattern Forceps.

Mr. A. H. H. **Sinclair** (Edinburgh) next read a paper describing an operation for intracapsular extraction of cataract by means of forceps of a new pattern, a modification of Kalt's forceps. He desired this contribution to the discussion to be regarded only as a frank statement of early results only, rather than as a complete record of finished work. Intracapsular extraction was no new procedure. Colonel Henry Smith had read a paper before the Association in 1903, being already able at that date to record experience of 6000 intracapsular extractions in India. After visiting Smith's clinic in 1911, Dr. Arnold Knapp, of New York, in 1912 began his work of intracapsular extraction. Dr. Knapp's subsequent writings had sufficiently indicated his method of procedure with blunt forceps (Kalt's) and expression.

Mr. Sinclair then detailed his own operation, speaking from an experience of 52 cases. He hoped that further experience would lead to improvement both of instruments and technique. The usual precautions were taken before the operation. The condition of the lens was examined with the pupil dilated: (1) by focal illumination; (2) by the ophthalmoscope; and (3) by the corneal microscope, two or three days before the operation. The type of cataract and the stage of advance were carefully investigated, but at present there was not sufficient certainty in the interpretation of appearances. The forceps were

Sir **WILLIAM WILLCOX** (London) said that there would be general agreement with Dr. McNee's classification of jaundice. It would be agreed by most people that a hæmolytic jaundice did occur, although it was relatively uncommon chemically; but the evidence for it from animal experiments was by no means convincing. He thought that by far the best evidence was to be found on the clinical side. Toxic and infective hepatic jaundice was, in his view, by far the most important type and the commonest. Jaundice of this type might be produced by poison, chemical, bacterial, or protozoal, or by auto-intoxication. The explanation of this type of jaundice was to be found in a consideration of the function of the liver which had been insufficiently recognised—the "toxiphylactic" function of the liver. The liver was the main protective organ of the body from poisons of all kinds, and in doing its duty in this direction was often irreparably damaged; the passage of bile into the bile capillaries was interfered with and jaundice resulted. The depth of jaundice was no measure either of the severity of the toxic action or of the degree of hepatic deficiency. Sir William Willcox drew attention to the variations that were found in the times that elapsed between the toxic action on the liver and the onset of jaundice. He stated that in catarrhal jaundice the lævulose test always gave evidence of impairment of hepatic function, and he was sure that the view of the French school was correct—viz., that catarrhal jaundice was a liver-cell degeneration set up by an intestinal bacterial infection.

Dr. **LANGDON BROWN** said that the old conception of hæmatogenous jaundice was returning in the new guise of hæmolytic jaundice. He thought the correctness of the French view of catarrhal jaundice had come out clearly, and he instanced cases of this disease in which the van den Bergh reaction was mainly indirect, while hepatic insufficiency was proved by the lævulose and lipase tests. Dr. McNee's work explained why splenic anæmia might arise from different diseases of the spleen, and it threw much light on latent jaundice.

Dr. **PLATT** brought forward some observations suggesting that in acholuric jaundice the red cells might actually develop an increased resistance to hæmolysis.

Mr. **R. H. PARAMORE** (Rugby) discussed the relationship of the blood flow through the hepatic capillaries with the rise of toxic jaundice, referring especially to the jaundice that is sometimes seen in the so-called toxæmias of pregnancy.

FRIDAY, JULY 25TH.

On the third day Prof. **F. W. EURICH** (Bradford), Vice-President, being in the chair, Dr. **W. MCCONNEL WANKLYN** opened a discussion on

Small-pox,

with especial reference to diagnosis. He dealt first of all with small-pox in its general bearing, and said that the essential thing in any such consideration was to surround oneself with the psychological atmosphere of small-pox, and he did not intend to delay in order to discuss the two main types of the disease and the clinical or pathological phenomena which distinguished them. Small-pox was not a beautiful scientific specimen to be cherished, it was a poisonous and devilish enemy to be put utterly to the sword. Small-pox had been protected, and was still being protected, in this country by misunderstanding and misrepresentation; it was one of the duties of the medical profession to tear down this cloak and expose the nakedness and foulness of the mischief behind it. Once small-pox was so displayed it would have short shrift.

Dr. Wanklyn then showed curves contrasting the percentage of London infant vaccinations with the percentage of freedom from small-pox in London. The striking feature of the curves was that whereas the percentage of infant vaccinations had fallen steadily since 1904 to less than 45 per cent. in 1921, yet the percentage of freedom from small-pox was higher than ever, and had been at a constantly high level for the past 20 years. This was not due to any diminution in the virulence of small-pox, or to any general decrease in its incidence. Small-pox in other parts of the world was still highly virulent, and competent observers estimated that there were at least one million cases of small-pox in the world every year. No explanation could be found in improved sanitation. He could state with authority and intimate knowledge that the one factor which had pulled small-pox down and which was now holding it down was the team-work of the profession and the voluntary civic spirit of its members. Small-pox abounded in the world at large, and it was as dangerous as ever to the people of these islands, whose decreasing use of vaccination had made them individually almost defenceless to small-pox, and had greatly increased the general risk. It had been countered only by the continued shepherding efforts of the medical officers and their colleagues, but for whose efforts small-pox would sweep again across these islands as calamitously as ever. The clearance of small-pox was a civic task that members of the medical profession must undertake in their capacity as citizens; they were not only citizens, but citizens with special knowledge whose duty it was to lead the way.

The one supreme weapon for holding small-pox was accurate diagnosis. Diagnosis might be said to be the discarding of the unimportant and concentration on the essential features of the case; and the first question on which hung all the rest was "Can this be small-pox?" To answer this question one should recall in methodical series the different varieties and stages of the disease. If small-pox cannot be eliminated by this process a more careful investigation of the lesions must be undertaken. For this a thoroughly good light and a view of as much of the skin as possible were desirable. Too much attention must not be paid to the old text-book signs—shottiness, umbilication, uniloculation, cropping, the rash being in different stages, or on the soles of the feet, spots on the palate. These were not sufficiently distinctive. The four master cards were: (1) prostration, (2) distribution, (3) localisation, (4) maturation, and of these distribution was the soundest of all; its key was that the rash of small-pox favours the irritated and shuns the unirritated surfaces. Prostration was not an absolute sign, but a copious rash preceded by complete absence of prostration was a strong argument against small-pox.

Dr. **C. KILLICK MILLARD** (Leicester), whose paper was read in his absence, said he thoroughly agreed with all the opener had said about the importance of accurate diagnosis, and he thought that no student should be allowed to qualify without giving specific evidence that he was at least able to suspect small-pox when he saw a case. He also agreed as to the unreliability of the old text-book signs. He divided the body into (*a*) trunk, (*b*) limbs, ignoring the head and neck. If after a careful count the lesions were more numerous on the limbs, the case was certainly one of small-pox; whereas if they were more numerous on the trunk it was almost certainly chicken-pox. There was no other single test of equal value to this distribution test. With Dr. Wanklyn's remarks on the general aspect of small-pox he was by no means in such complete agreement. He was unable to foretell what the future had in store for Leicester, but he had always said that whenever small-pox visited Leicester it demonstrated unmistakably the power of vaccination to protect the individual; but it also demonstrated that the orthodox view as to the great value of infant vaccination in protecting the community was greatly over-estimated. Although he agreed with Dr. Wanklyn's lucid description as applied to Asiatic small-pox, he thought it was unfair to apply it to the American form. Alastrim small-pox was not a deadly or disfiguring disease, although it was undoubtedly true small-pox. He disagreed with Dr. Wanklyn's estimate of the cost to the community of dealing with an outbreak of small-pox, but he associated himself heartily with the plea to develop team-work so as to sweep the disease out of the country.

Dr. R. P. GARROW gave an account of the epidemic of mild small-pox prevalent at Chesterfield. The disease as it existed in Chesterfield differed strikingly in many ways from typical virulent small-pox. It was milder, less infective, and was controlled by a less degree of vaccination. It was not characterised by scaring, the rash was small in size and unilocular, and evolution was more rapid. The crust formed was not the typical crust of small-pox, because the lesions did not go on to real pustulation; it appeared rather as an agglomeration of golden grains, as if due to the drying up of a clear serum. So far as the Chesterfield epidemic was concerned, no cases of virulent small-pox had occurred.

Dr. E. H. SNELL (Coventry) thought that the main difficulty caused by the present epidemic of mild cases was the administrative use of controlling it. The man in practice was met by cases which showed only a few pimples so negligible that the patient said nothing about them. There was nothing about the cases in the ordinary way to arouse suspicion of small-pox, and so they went unrecognised and continued to spread the disease.

Dr. J. A. WATT described the epidemic at Derby, which was very similar to that at Chesterfield.

Dr. EURICH read a paper on the *Clinical Features of Anthrax*, illustrated by lantern slides. He described the clinical appearances of the pulmonary and intestinal forms of the disease. In these forms the disease was so rapidly fatal that there was no time to undertake any laboratory investigations that might possibly prove helpful in establishing the diagnosis. He emphasised the fact that in cutaneous anthrax the diagnosis was bacteriological, and that microscopical examination for the anthrax bacillus should be made by the practitioner himself without delay. As regards treatment, he did not excise the pustule except in special cases; the part was kept absolutely at rest and Sclavo's serum injected, 80 c.cm. being given for the initial dose; a second dose of 60 c.cm. followed 18 hours later, with more injections later if needed.

Dr. F. C. EVE (Hull) read a paper on the *Domestic Estimation of Urinary Sugar*, describing a method by means of which patients can themselves measure the daily excretion of sugar. Every night the patient passes urine into a clean thermos flask. The specific gravity of the urine is taken and a lump of yeast is added to the urine. The flask is corked with cotton-wool. After fermentation the specific gravity is again taken, and will be reduced to an extent proportional to the amount of sugar originally present. The resulting specific gravities are charted daily in two curves, the closer the two curves approximate the less the sugar excreted.

SECTION OF OPHTHALMOLOGY.

WEDNESDAY, JULY 23RD.

The President of this section, Mr. A. MAITLAND RAMSAY (Glasgow) referred to the loss which the section had recently sustained through the death of one of their vice-presidents, Mr. G. H. Oliver (Bradford). As Prof. IGNACIO BARRAQUER (Barcelona) had been prevented from attending the meeting to open the discussion, the Secretary (Dr. J. D. McCulloch) read Dr. Barraquer's paper on

The Intracapsular Method of Cataract Extraction.

Dr. Barraquer in his paper described the classical operation by cystotomy as extraordinarily imperfect from a surgical point of view. It involved (1) making pressure on the eyeball; (2) retention in the eye of the greater part of the capsule and some of the cortex of the lens; and (3) the entrance of unnecessary instruments into the eye. The many methods of intracapsular extraction, devised by Daviel and others from 1745 onwards, fell into two groups (1) by traction and (2) by pressure. The traction methods of Kalt and Knapp were those most frequently adopted in the former class, but had never become popular. The instruments employed usually tore the capsule, and the operation became an ordinary cystotomy with all its inconveniences, aggravated by the complications caused by severe traction on the zonule. Smith's brilliant successes had demonstrated the great advantages of intracapsular extraction, but in other hands his operation had not met with equal success. Dr. Barraquer said that in 1916 he arrived at the idea of a pneumatic forceps (cup) that would grasp the lens by its anterior face, and without breaking its capsule, by stretching, would detach it from its attachments and pull it out entirely. Experience showed the advantage of rupturing the fibres of the zonule close to the lens instead of at their ciliary attachment. This he secured by giving a vibratory movement in the vacuum. The large iridectomy, done in the earlier cases, proved to be unnecessary; the adoption of the Hess peripheral iridectomy and the previous suturing of the conjunctival flap improved the operation; the paralysis of the orbicularis by injection of novocaine by Van Lint-Millard's technique was also adopted. Among the indispensable conditions for successful performance of his operation were the use of a perfect erisiphaque, well regulated beforehand with reference to the physical conditions of the cataract on which the operation was to be done, the avoidance of all pressure on the eyeball, and the preservation of the sphincter of the iris. In his own clinic, failure to secure a black, central, round pupil with 8/10 vision was exceptional. The advantages of his operation were specially noteworthy in diabetic and myopic cases. Vitreous ruptures and iritis occurred less frequently than with the old operation. He said that he had practised cataract extraction by capsulotomy for 16 years, and by phaco-eresis for eight years, and during the latter period the percentage of patients with normal visual acuity was more than double that in the former period; and the number of operative accidents and post-operative complications had diminished in the same way. The technique was not difficult, though completely different from that of other operations. Recent statistics published by Dr. Basterra (Madrid), Saint-Martin (Toulouse), Guiral (Habana), Green (San Francisco), and others showed the success of the operation in other hands.

Technique of Operation with New Pattern Forceps.

Mr. A. H. H. SINCLAIR (Edinburgh) next read a paper describing an operation for intracapsular extraction of cataract by means of forceps of a new pattern, a modification of Kalt's forceps. He desired this contribution to the discussion to be regarded only as a frank statement of early results only, rather than as a complete record of finished work. Intracapsular extraction was no new procedure. Colonel Henry Smith had read a paper before the Association in 1903, being already able at that date to record experience of 6000 intracapsular extractions in India. After visiting Smith's clinic in 1911, Dr. Arnold Knapp, of New York, in 1912 began his work of intracapsular extraction. Dr. Knapp's subsequent writings had sufficiently indicated his method of procedure with blunt forceps (Kalt's) and expression.

Mr. Sinclair then detailed his own operation, speaking from an experience of 52 cases. He hoped that further experience would lead to improvement both of instruments and technique. The usual precautions were taken before the operation. The condition of the lens was examined with the pupil dilated: (1) by focal illumination; (2) by the ophthalmoscope; and (3) by the corneal microscope, two or three days before the operation. The type of cataract and the stage of advance were carefully investigated, but at present there was not sufficient certainty in the interpretation of appearances. The forceps were blunt and toothless. The lower margins of the blades, which came into apposition when the instrument was closed, had a specially designed curve, were smooth, and met in a clamp-like manner. The shanks of the forceps did not meet, and all projecting parts were carefully rounded off so as to cause no injury to the cornea or iris. The correct apposition of the blade margins was insured by stops on the handles. Too great pressure was prevented by an adjustable nut on the lowest stop. The upper aspect of the closed blades formed a small spoon-shaped or boat-shaped cavity or cup. This was directed upwards when the instrument was in position, and could be clearly seen through the cornea. The lower aspect of the closed blades was convex and keel-like, and when the instrument was first placed in position rested lightly upon the central part of the anterior capsule of the lens. This forceps, which he had had in use in its present form for some time, was modified from a pair of Kalt's forceps purchased in New York in 1920. It had been modified in size, in shape, and in action. Recently he had found that the capsule of the lens seldom gave way where the forceps took hold, and he believed that this was in part due to the construction of the instrument.

Hitherto, Mr. Sinclair said, he had always performed iridectomy, and immediately after iridectomy the forceps were used. The blades were introduced closed through the central part of the incision with the point tilted downwards, so as to raise the edge of the corneal flap. As soon as the closed blades reached a position at, or a little beyond, the centre of the lens, they were placed, still closed, lightly on the lens capsule, and opened widely to 4 or 5 mm. During the opening movement the blades were held in light contact with the surface of the lens. The pupil margins, which he had often seen in contact with the outer aspect of the blades, were gently pressed asunder, and he had never seen the iris injured in any way or caught by the forceps. When the opening movement of the blades ceased, the closing movement should begin without any delay, and, as this closing movement began, the blades were gently pressed against the lens capsule. This gentle pressure was increased as the closure proceeded, so that the convex edges of the clamping margins of the blades dimpled or indented the capsule into the soft subcapsular cortex of the lens. As the closing blades approximated the pressure on the lens was progressively increased, and at this stage it could be clearly seen through the cornea that a relatively large mound of capsule-covered cortex was forming between the blades. When the closure was complete the cup of the forceps contained quite a considerable mass of capsule-covered cortex. This contained cortex distended the portion of capsule within the cup, and, during the traction which followed, prevented it slipping from between the lower margins of the blades, and thus too great pinching pressure upon the capsule was unnecessary. The construction and large size of the blades also helped to spread or distribute the strain upon the capsule. The degree of approximation or pressure of the blade margins was arranged prior to the operation by the setting of the adjustable nut on the lowest stop between the handles. Immediately the forceps had been completely closed, a gentle forward movement towards the centre of the cornea was made, and the forceps held forward in this position for an appreciable period, say for five seconds or more. This first movement forward put the lens capsule on the stretch all round and began the moulding of the lens. When this forward movement was considered sufficient, the direction of traction was altered so as to bring the greatest degree of tension to bear upon one part of the suspensory ligament at a time. "If we suppose the cornea to be marked like a clock face as viewed from the front," he said, "I should begin the lateral traction forwards and to the side, towards 2 o'clock, and afterwards towards 10 o'clock, and then towards 12 o'clock, always maintaining a partially forward movement." The suspensory ligament appeared to give way at one place at a time, and always below the horizontal meridian. Once the rupture of the ligament had begun the subsequent separation was much easier, and the ligament seemed to strip off from the lens margin. In cases where the zonule gave way easily the above stages of the procedure might not be noticeable. At this stage, which lasted often about half a minute, but had varied from 10 to 15 seconds in one case to 60 to 70 seconds in another, the lens began to yield and to come forward at the lower part. The forceps traction was constantly maintained but with a little less strength so as to bring the lens forward and towards the wound very slowly. This slow, gentle but continuous traction, which Mr. Sinclair had found to be the best, gave time for the separation of the remaining suspensory ligament attachments, and also for the slow separation of the lens from its bed upon the anterior surface of the vitreous humour. The lens underwent considerable alteration of shape from traction, &c. Care must be taken to prevent sudden exit of the lens when its largest diameter was emerging. Stroking of the cornea usually sufficed for reposition of the iris. Atropine was used either before operation or immediately after.' There had been loss of vitreous in seven cases, of which four were slight. Only in three cases had the effect on vision been serious. Thirty-two cases obtained vision of six-ninths or more.

Mr. Sinclair desired to express his indebtedness to Dr. Charles W. Graham, senior clinical tutor in the ophthalmic department at Edinburgh, for his very able and skilful assistance in this series of cases. A cinematograph film of the operation added to the interest of the paper.

Discussion.

Lieut.-Colonel Henry Smith, I.M.S., said a liberal incision was a sine qua non. For a Morgagnian cataract, expression was the only method. Complicated mechanism of Barraquer's instrument was a serious objection. Green (San Francisco) combined external pressure with the use of Barraquer's instrument. Minute investigation of the physical condition of the lens was not of great practical import. A swollen lens implied a fragile capsule. Intracapsular extraction had great advantages in cases with adhesions of the iris. He agreed that a large escape of vitreous was as fatal a disaster as a choroidal hæmorrhage. A small escape of vitreous was not serious, for it did not prevent retention of perfect vision for 20 years or more after the operation. He advocated controlling the upper lid during operation by an adjustable form of retractor affixed to a metal headband.

Mr. M. L. Hepburn (London) criticised Barraquer's method; its advantage did not counterbalance its dangers. He and his colleagues at the Moorfields Hospital had abandoned the operation, as their experience of it was unfavourable. In his opinion it was not to be recommended as the operation of the future.

Mr. J. Gray Clegg (Manchester) was not in favour of Barraquer's operation. The mechanism of his apparatus was too complex. Inquiries he had made as to the results obtained had led him to form an unfavourable opinion.

Mr. N. Bishop Harman (London) endorsed this view. He wanted more simplicity in operations. Colonel Smith's instrument for controlling the upper lid appeared likely to alarm the patient needlessly. Mr. Sinclair's method of operating looked simple and worthy of a trial.

Mr. Harrison Butler (Leamington) urged that the old operation yielded such good results that a rival operation must have strong claims to superiority to justify its adoption. He endorsed what other speakers had said of the great value of producing paralysis of the orbicularis by injection of novocaine.

Mr. R. J. Coulter (Newport) thought Colonel Smith's lid retractor unsuitable.

Mr. A. L. Whitehead (Leeds) referred to the need for simplicity in the apparatus employed in operating.

Smith's operation was not the operation of choice, as the average operator could hardly acquire the dexterity which had made it so successful in the hands of its originator. The operation which will produce the best results in the hands of the average operator, he said, was the one at which we should aim. During 25 years he had given systematic trial to various operations, and had finally come back to the old classical one. He very rarely had occasion to use novocaine to control the patients' lids.

Mr. E. E. MADDOX (Bournemouth) said he had done about 40 to 50 intracapsular operations, about half of these by Smith's method, and the others by the aid of a special form of vectis. In some cases Smith's operation was far superior to the ordinary one. He thought the operation of the future would be by the combined method, some pressure from the outside combined with sensible suction.

Mr. A. LITTLE (Bradford) gave a warning against discarding a very safe operation for one attended by considerable risks.

Mr. GORDON SPENCER (Mesopotamia) said we must have a simple operation. What he had seen of Smith's operation in other hands did not justify its general adoption. Barraquer's complicated apparatus was hardly suitable for conditions in Mesopotamia.

Mr. O. G. MORGAN (London) mentioned that in the Moorfields cases striate keratitis of some duration had followed Barraquer's operation. A little vitreous in the wound was as dangerous as a little capsule or iris. The classical operation was neither difficult nor dangerous.

In replying on the discussion,

Colonel SMITH said that experience in India would be the deciding factor in this controversy. His first pupil was now doing as many as 8000 cataracts a year in the Punjab. Mr. SINCLAIR said that he quite agreed with the plea for simplicity; that was one reason for the adoption of his present instrument instead of Barraquer's. Remains of cortex sometimes spoiled the results of the old operation.

Mr. A. L. WHITEHEAD then read a short paper on cases of paresis of accommodation occurring as a late symptom in encephalitis lethargica. These cases had most of them been diagnosed as influenza. The paresis had come on late in cases of slight severity. There had been slow and progressive improvement. His purpose in calling attention to these cases of partial cycloplegia was to emphasise its significance as a diagnostic sign.

THURSDAY, JULY 24TH.

Microscopy of the Living Eye.

At the second meeting of this section the chair was taken by Mr. R. J. COULTER (Newport), one of the vice-presidents, and the morning was devoted chiefly to the consideration of points arising in connexion with the use of the slit-lamp in investigating the anatomy and pathology of the living eye.

Mr. BASIL GRAVES, curator at Westminster Ophthalmic Hospital, and British Medical Association Science Research Scholar, read the first of the opening papers. His contribution, dealing with the normal eye, was restricted to presenting two features—one relating to the optical section of the aqueous fluid, the other to the optical section of the normal lens. It was customary, he said, to refer to the normal aqueous fluid as optically empty; he had been able to demonstrate that this was not the case. "The normal aqueous fluid, though admittedly only slightly so, is relucent." To demonstrate this relucency, a round beam of very small diameter should be used. With the ordinary Zeiss nitra slit-lamp the 1 mm. diameter dot diaphragm should be used; when using the arc slit-lamp the 0·5 mm. dot aperture is preferable. The beam should be directed at a suitable angle so as to avoid the corneal epithelium; it should be focused carefully midway between the cornea and lens; the beam should not strike the iris, for which reason it was an advantage to have the pupil dilated. The slit-lamp arm should be made to oscillate slowly up and down, so as to give movement to this faint beam, which will thereby be seen the more easily, and if a beginner, the gaze should be directed a little above or below the level at which he seeks to see the beam, so that its image may fall on the peri-macular retina. Mr. Graves held that this question of relucency of the aqueous was no mere scientific curiosity, but of practical importance in detecting the incipient stages of certain diseases. It was therefore advisable for the observer to have trained himself so as to appreciate the normal range of relucency of the aqueous fluid.

The second point to which he wished to call attention was the observation in the optical section of the lens of a restricted portion, differing from the rest of the lens section in having an almost metallic lustre. This was best seen often in a normal senile cortex, but was also met with, if carefully looked for, in younger lenses. The explanation of this phenomenon he believed to be that it was caused by a summation of successive multiple specular reflections from the laminated elements of the cortex. Further observations were necessary to elucidate the significance of this feature; possibly it might have some bearing on the prognosis of senile cataract. In concluding, Mr. Graves expressed his indebtedness for the facilities afforded him in his work on this subject at the Royal London Ophthalmic Hospital and at the Royal Westminster Ophthalmic Hospital.

The second opening paper was given by Mr. HARRISON BUTLER, who dealt with the pathological aspect. His paper was illustrated by a very fine series of lantern slides. Time prevented dealing with more than the fringe of so vast a subject. By the aid of the slit-lamp it was possible in ulcers stained with fluorescein to see how the green coloration passed along the lymph spaces, and penetrated deeply into the substance of the cornea. The slit-lamp, with its accurate localisation, enabled us to decide whether an abnormal condition observed was in the epithelial surface of the cornea or in the anterior, middle, or posterior lamellæ of its stroma. In herpes ophthalmicus a characteristic lesion was met with just inside Bowman's membrane. Folding of Descemet's membrane was seen with the slit-lamp in most inflammatory states of the anterior segment of the eye, and also constantly after operations upon the cornea. Such folds are invariably present in interstitial keratitis. In the late phases of an interstitial keratitis, when it appeared by other cruder methods of observation that the corneal vessels were functionless and atrophied, the slit-lamp would show that these fine vessels still permitted active flow of blood. The examination of the anterior chamber with the slit-lamp is, he said, of the very highest importance with reference to inflammatory states of the anterior segment of the eye. Keratitic precipitates (K.P.) can be detected when so small that they are apt to be overlooked by the older methods, and under high magnification much can be learned of their nature and significance. We are liable to regard flakes of absorbing cortex on the surface of the cornea as "mutton fat K.P." and to become unduly alarmed. "Black K.P. is very common after operation involving the iris, and I regard it as perfectly harmless." The detection of cellular elements in the aqueous may be the first sign of sympathising ophthalmitis and can give us timely warning of this formidable condition. The great advantage of the slit-lamp in the examination of the iris is that in addition to giving us a highly magnified stereoscopic picture of the superficial area, it enables us to illuminate from behind and see the iris in lens light. If there is any atrophy of the retinal pigmentary layer, or holes in this tissue, the light shines through and the condition is made evident. The various forms of cataract can be localised and minutely examined with the slit-lamp and the Czapski microscope. It is often possible as the result of this localisation to decide at what period of life an opacity developed. The slit-lamp has furnished so much information regarding the anatomy and pathology of the lens that all text-books are obsolete in this connexion. From the operative standpoint the slit-lamp is indispensable, for it gives an accurate knowledge of the nature of the cataract that we propose to extract or needle, and allows us to detect the earliest signs of inflammation both before and after operation. "I have already refused," he said, "to extract a lens that I should have operated on had the slit-lamp not forewarned me of chronic cyclitis." The appearances of the vitreous are varied and often very beautiful. It is hard to realise that a normal perfectly transparent vitreous is actually full of massive fibrils, of membranous films, and punctate opacities. It is hard to separate the physiological from the pathological. Considerable experience is requisite. At present examination of the retina by this method hardly comes within the scope of ordinary clinical work.

In conclusion, Mr. Butler said he had no doubt of the value of the slit-lamp. The ophthalmologist who had mastered its technique and had given enough time to the subject had raised himself to a higher plane of craftsmanship than before.

Mr. C. B. **GOULDEN** (London) followed with a short paper dealing with the reflections from the various surfaces of the eye. The surfaces of the cornea and lens acted as mirrors, each showing three methods of reflection: (1) By forming a real or virtual image; (2) by reflecting light diffusely, as every object which we see does; (3) by specular reflection. The best example of this in ordinary life is the peculiar reflection from the surface of a blackboard, with which most of us were familiar as schoolboys, which prevented us reading what was written on it. Another instance was the "specular reflection" from the painted surface of a door, in which one could see fine marks of the painter's brush, which could not be seen ordinarily. Similarly, in examining the eye certain irregularities in the reflecting surfaces could be made out by means of the specular reflection which could not be seen by any other means.

Mr. O. G. **MORGAN** (London) read a paper embodying observations made with the slit-lamp in a series of cases of cyclitis. In several of the cases definite iridescence of the posterior capsule of the lens was observed, in only one of which could any definite opacity be made out in it.

Mr. **HUMPHREY NEAME** (London) read notes of a case of posterior stellate cataract following trauma, in which the opacity disappeared completely in the course of a few weeks. The opacity showed the typical feather-shaped stellate appearance. Seventy-one days later no trace whatever of any lens opacity was found.

Mr. **GRAVES**, in replying, said that at present he did not feel that the slit-lamp was of real clinical value in the investigation of the vitreous. Vitreous dust could be seen as clearly with the electric ophthalmoscope, using a plane mirror and a high plus lens.

Mr. **BUTLER**, in replying, said that we knew so little about the vitreous at present that examination of it with the slit-lamp was more likely to lead us astray than otherwise.

At the Royal Eye and Ear Hospital, Bradford, in the afternoon of the same day, an interesting demonstration was given of the use of the slit-lamp. Various cases were shown. Mr. A. H. H. **SINCLAIR** and Lieut.-Colonel H. **SMITH** also demonstrated their methods of intracapsular extraction of cataract in the operating theatre.

Mr. J. A. **WILSON** (Glasgow) read a short paper on Sympathetic Ophthalmitis and Allied Conditions. Starting with the question, "How is disease of a particular type transferred from one eye to the other?" he discussed possible analogies with herpes and other diseases, and the question of transference of infective material by means of the perineural lymph spaces.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal statistics for 1923 of four cities and a county borough, the health reports of which are commented on below. The contrast between the mortality from respiratory diseases in the group and that in the group of "mill-towns" tabulated in our issue of August 2nd is marked.

Name of town.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Edinburgh ..	425,298	20·4	13·8	1·3	1·5	2·1	33	82	5·9
Brighton ..	135,802	16·0	12·4	0·9	1·8	2·1	27	60	0·8
Norwich	123,600	19·4	10·9	1·2	1·3	1·8	40	65	2·5
Carlisle	54,010	21·8	13·5	1·0	1·4	1·8	40	83	7·6
Worcester ..	49,860	18·5	10·9	1·1	1·1	1·7	30	57	2·1

Edinburgh.

Dr. William Robertson emphasises the fact that two accurate pointers to faulty environment are to be found in the tuberculosis and infantile mortalities. Thus St. Giles's Ward had a tuberculosis death-rate of 1·8, an infantile mortality figure of 109, and the central ward of Leith had an infantile mortality-rate of 111. "Too much must not be expected from the mere provision of houses fitted with modern conveniences. The cry of houses for the people is just, but it must not be uttered parrot fashion. Good housing must be accompanied by better behaviour, cleaner habits, and improved ideas of good citizenship." In the case of 852 overcrowded houses it was only possible to abate the overcrowding in 91 cases by means of removal or other arrangements. Dr. Robertson hopes the housing committee will ever keep in the forefront of its policy the liberal provision of recreation facilities for the children. An analysis of the working-class population shows that there are three classes. First, those who will gladly pay economic rent for modern houses; secondly, those who say they cannot afford to pay such rents; and thirdly, those who are undoubtedly poor. Among the latter classes are the people paying rents of 9s. and 11s. per week for one- and two-roomed farmed-out houses. A report has been made to the health committee on the question of providing a hostel for men and a hostel for women, and Dr. Robertson thinks there need be no hesitation in proceeding with these revenue-producing schemes. The Scottish Board of Health have approved the scheme for the clearance of the blackest spots of the Cowgate and Grassmarket. It is hoped that progress will be made when houses are ready for the occupation of the displaced tenants.

Towards the latter end of March the Broughton district suffered from an outbreak of milk-borne scarlet fever. The milk-supply came from the county of Linlithgow. The supply of this milk to Edinburgh was stopped, but the diversion of the infected milk to another consuming district led to a violent explosion of scarlet fever in that locality. The cow population in the city is 4281, and amongst these 24 cases of tuberculosis of the udder and three of advanced tuberculosis were found during the year. The four grades of milk recognised by the Scottish Board of Health are being used and the prices charged for milk from tuberculin-tested cows do not stand in the way. In the case of the first three grades producers are required to supply milk with a butter-fat content of 3·5 per cent. About 25 per cent. of the milk sold in the city is now supplied in bottles. The fourth grade of milk—namely, pasteurised milk—will soon be turned out in very large quantities and is welcomed by Dr. Robertson in view of the widespread milk-borne epidemics of scarlet fever which attacked the city in 1913, 1915, 1919, and 1921. The ordinary period for retention of scarlet fever patients in hospitals has been reduced from six or seven weeks to four weeks, in view of the want of evidence as to the infectivity of desquamating cases. More accommodation is thus set free for measles and whooping-cough. A disconcerting experience has been the appearance of a more virulent type of scarlet fever during the autumn. Thus the case-fatality of scarlet fever was 5·2 per cent. as compared with 1·9 per cent. in 1922. The Schick test for diphtheria is being utilised. The whole of the staff at the hospital have been immunised.

Dr. David Lees, the V.D. clinical medical officer, reports that the total number of patients who discontinued attendance before they were considered free from diseases amounted to 15·6 per cent., as compared with 18·5 during 1922. Although this is comparatively a satisfactory figure, Dr. Lees strongly favours some system of notification. At the beginning of the year 24 beds were allocated for the treatment of women and children at the Royal Infirmary and Royal Maternity Hospitals, and these beds have been fully occupied and of great assistance in treating innocent patients without any stigma being attached to them.

Dr. Robertson points out that the cost of dealing with tuberculosis during the past year was £35,160, whereas the cost of treating all other infectious diseases was £41,578, and he thinks this figure should prove an incentive for aiming at improved sanitary environment. The treatment of surgical tuberculosis by artificial sunlight is to be given a trial.

Brighton.

Dr. Duncan Forbes says Brighton's chief difficulty is inability to build large numbers of houses which can be let at economic rents, so as to overtake the present shortage and allow the slums to be swept away. He points out that the census figures show a large decrease in the number of men employed in the building trades and that the position is not hopeful unless there is dilution of labour or increased output by the individual workers. A table is given showing that the net expenditure of the Health Committee, exclusive of housing, is just under a 6*d.* rate and that for the school medical service just over ½*d.* rate. The club-room provided for male consumptives continues to fulfil its purpose of providing a place of interest and enjoyment under open-air conditions and simultaneously a certain measure of segregation. Members of the club attended 3553 times on the 311 days the club was open. It is now a condition that patients who book for the Sussex Maternity and Women's Hospital should attend the antenatal clinic. A dental clinic is now available for nursing and expectant mothers and children under 5 years of age, but only 57 per cent. of these patients kept the appointments made for them. Nearly all the midwives in Brighton now adopt the routine practice of treating the infant's eyes at birth with a 10 per cent. solution of argyrol. Seventeen cases of ophthalmia neonatorum were notified, 12 being very mild. No case of puerperal fever was notified during 1923.

The Milk and Dairies (Amendment) Act, 1922, is being operated. Early in the year 61 shops where milk was on sale were dealt with. In 20 the sale of milk was discontinued; in 27 the sale was only allowed in bottles; in 10 cases special compartments or rooms were set aside for the sale of milk; in one case the sale of greengrocery was given up, and in three cases no structural alteration was found necessary.

Regulations have now been made by the council for the prevention of eye-strain in cinema theatres as follows: (1) In the case of new or reconstructed theatres no seat shall be nearer to the picture-screen than 20 feet, and every seat must be so placed that the angle made by a line drawn from the top of the screen to the eye of the spectator shall make with the horizontal an angle of 35° or less; (2) in the case of existing theatres the minimum distance is 15 feet and the angle must not exceed 45°.

In his school report Dr. Forbes gives an interesting résumé of the improved present conditions of children who have recently undergone operations for tonsils and adenoids. He also reports that the zinc ionisation treatment of discharging ears has given very satisfactory results. Out of 104 cases of chronic otorrhœa 78 have been cured. In other cases deemed unsuitable for the treatment improvement has nevertheless resulted either by the lessening of the offensive odour or the reduction in quantity of the discharge. Nutrition tables for school-children of all ages have been drawn up as the result of much hard work by Dr. O. J. W. Adamson. These tables will be used in order to decide if the provision of meals, cod-liver oil, &c., is necessary.

Norwich.

Dr. H. Cooper Pattin reports that the natural increase in population continues to outstrip the supply of new dwellings. The increasing scarcity of houses compels toleration of undesirable habitations, prevents their closure, and intensifies overcrowding. A feature of much house property in the city is its worn-out condition, which makes reparation hopelessly unprofitable. Dr. Pattin hopes ultimately to see "all types of tuberculosis, pulmonary and non-pulmonary, hospital, sanatorium, colony, at all ages and in both sexes treated at Stanning Hall, where there is ample space and where also the aggregation of these folk should lead to considerable economy in administration expenses." He does not, however, think the special provision of institutional treatment for cases past recovery will serve any useful purpose until statutory power of compulsory segregation is conferred. The school dental officer finds defects in 68·2 per cent. of those whom he inspects.

Carlisle.

Dr. Joseph Beard comments at length on the failure of the system of notification of tuberculosis. Only 55·5 per cent. of the fatal cases lived more than three months after notification. It is found at the dispensary that 82 per cent. of the insured persons notified are in the late or advanced stage of the disease. Of 54 deaths which occurred within six months of notification 24 were insured persons. On the other hand, of the school-children referred to the tuberculosis dispensary, 82 per cent. come under observation at an early and hopeful stage of the infection.

Worcester.

Dr. Mabyn Read reports that the building of new houses does not keep pace with the growth of the population and that the shortage is getting worse year by year. Under present conditions closing orders cannot be made and the law cannot be put into operation with regard to gross overcrowding. Two small unhealthy areas have been "represented," occupied by 128 and 244 persons respectively, but no action can be taken until 80 houses "suitable for occupation by the poorest paid section of our population" have been erected. In October the female block of H.M. Prison was taken over by the council for housing purposes. In answer to an advertisement 170 applications were received and 18 families, comprising 54 adults and 56 children, are now housed in the "Castle." The rents payable by these tenants vary from 4*s.* 6*d.* to 7*s.* 6*d.* per week, which includes rates, gas for lighting and heating of corridors and cells. The accommodation provided for each tenant consists of one good living-room and a sufficient number of cells to give bedrooms for

the families concerned. Water-supplies and sinks are convenient and a large laundry provides ample facilities for washing purposes. Gas-stoves on the slot principle have been provided for cooking purposes.

Dr. Marion B. Andrews, the maternity and child welfare medical officer, reports a growth in the utilisation of home-helps, in the provision of dinners, and in the dental work. Where possible the provision of dinners for pregnant and nursing women is preferred, as being less likely to be diverted from its destined end than the issue of milk. The dinners are organised by the Infant Health Society, which, as Dr. Andrews tells us, is responsible for a great deal of valuable work. The rule is made that mothers pay £3 towards the cost of dentures, and it is pointed out that this charge is a serious obstacle for the mothers of families who are on the 'free-scale' in other respects. The limit of the 'free-scale' is a family income of 6s. per head, and, as Dr. Andrews puts it, the prospect of saving 60s. in a reasonable time on such an income is extremely remote. Nearly half the infant deaths were attributed to prematurity, and took place during the first fortnight of life. Dr. Andrews thinks these babies are usually washed and fed as normal children and some endeavours are now being made to meet their peculiar needs by stocking supplies of cotton-wool and olive oil for the use of the midwives. Classes for mothers have made progress, and the experiments of setting simple examination on mothercraft subjects has proved a success.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 26TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 52; scarlet fever, 1459; diphtheria, 670; enteric fever, 102; pneumonia, 457 (as against 570 of the previous week); puerperal fever, 38; cerebro-spinal fever, 9; acute polio-myelitis, 17; acute polio-encephalitis, 4; encephalitis lethargica, 69 (as against 81 of the previous week); dysentery, 4; ophthalmia neonatorum, 110. There were no cases of cholera, plague, or typhus notified during the week. Of the 52 cases of small-pox, 13 were notified from the county of Derby (Derby 2, Chesterfield 9, Chesterfield R.D. 1), 19 from the county of Northumberland (Ashington 18), 6 from the county of Nottingham (Hucknall 3, Mansfield 3), 2 from the county of Warwick (Coventry), 3 from Yorks, North Riding (Middlesbrough), and 9 from Yorks, West Riding (Rotherham C.B. 1, Rotherham R.D. 7). Of the cases of encephalitis lethargica, 8 were notified from the County of London (Bethnal Green 1, Deptford 1, Islington 1, Lambeth 1, Shoreditch 2, Stoke Newington 1, Woolwich 1), 5 from the county of Chester (Stockport 2), 2 from the county of Derby (Derby), 5 from the county of Durham, 3 from Essex (West Ham 2), 10 from the county of Lancaster (Manchester 4), 5 from the county of Stafford, 6 from the county of Warwick (Birmingham 3), and 5 from Yorks, West Riding (Sheffield).

Deaths.—In the aggregate of the great towns there was an increase of 12 in the total deaths. In London the number of deaths from all causes decreased from 750 to 729.

Royal East Sussex Hospital.—The year just ended in connexion with this institution at Hastings has been an anxious one. It has been marked by the removal from the old home to the present new institution, which was opened in November. A curtailment of its activities was necessitated for a time, during which there was a considerable falling off in the receipts from patients, and with a larger institution the larger had been the expenses without any increase in the income. The year was not a normal one, and the balance-sheet, which showed an excess of expenditure over income of £3524, cannot be accepted as a basis for the future. At the annual meeting on July 28th the governors, however, took a very wise step in adopting a suggestion which came from the mayor (Councillor Arthur Blackman) and appointed a committee to investigate the financial position. The findings of the committee will be watched with much interest by everyone interested in the administration of hospitals. It may be hoped that the committee will thoroughly thrash out the reason why the number of subscribers residing in Hastings and St. Leonards is out of all proportion to the size of the town.

Obituary.

THOMAS DAVID LISTER, C.B.E., M.D., B.S., M.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING PHYSICIAN, PRINCE OF WALES'S HOSPITAL FOR CONVALESCENT OFFICERS, MARYLEBONE, AND TO THE ASSOCIATION OF LOCAL GOVERNMENT OFFICERS.

We regret to announce the death on July 30th of Dr. T. D. Lister, whose work in connexion with tuberculosis and with life assurance problems was of high value. Born in London on Jan. 30th, 1869, the son of Francis Wilson Lister and Elizabeth Wishart, only daughter of David Roy, of Glasgow, he received his early education at the Haberdashers' Company School, entering Guy's Hospital, where he qualified with honours in 1892. He was house surgeon there and pathologist to the East London Hospital for Children, but did not remain on the staff of a general hospital. Later he became physician to the Mount Vernon Hospital for Consumption, consulting physician to the National Union of Teachers, to the Post Office Sanatorium Society, to the Association of Local Government Officers, and, for chest cases, to the Prince of Wales's Hospital for Officers at Marylebone. He was also a lecturer at the London School of Clinical Medicine. He was advisory physician to the National Sanatorium Association, a body concerned with the establishment and maintenance of sanatoria for workers suffering from tuberculosis, and as chairman of its sites and buildings subcommittee he drafted the scheme for the Benenden Sanatorium. He was an invited member of the panel committee of the County of London and of the Hospital Fund Board of Delegates.

Lister was a man of many interests and of great industry, and it was surprising to his friends how much valuable work he contrived to carry out. One side of his bent is shown by his undertaking to edit (1912) a new edition of Chavasse's popular Advice to a Mother. He possessed a keen, incisive, logical mind with a definite mathematical bias, which no doubt helped to determine his interest in the problems of life insurance and the industrial aspects of disease, more particularly of tuberculosis. In both of these subjects Lister was a recognised authority; indeed, one of the foremost, as his writings prove. With originality and real vision he possessed a deep fount of common sense, which combined to render his views both suggestive and practical. The mere list of his appointments affords a measure of his special experience of the problems of tuberculosis, more particularly as they affect the community. He was a trenchant critic of commonly accepted views where they were not supported by clear and logical evidence. Two books dealing with industrial tuberculosis (1910) and sanatoria for the people (1911) illustrate this point. Although he was on the staff of one sanatorium and helped to draw up the scheme for another, he saw the weak points in the institutional treatment of this disease and worked hard to suggest remedies for them.

Lister's knowledge of the problems of life assurance was profound. He was one of the chief medical officers of three insurance offices. It was characteristic of him that he was not content to study the medical problems of life assurance only, but that he also endeavoured to get a grasp of the actuarial and the business aspects of this important subject. His presidential address before the Assurance Medical Society on March 3rd, 1920, was a thoughtful, original, and suggestive essay, indicating numerous lines for future investigation and research. In it he developed an ingenious idea of vital trajectories. In 1921 he published a book on the Medical Examination for Life Assurance, a handy and conveniently arranged volume, which has been of the greatest service to those working in this branch of medical practice. It is likely long to remain a standard manual on this subject. Unfortunately his health gave way shortly after its publication. "There can be

little doubt," writes one of his friends, "that the comparatively early death of his father and one of his brothers hung as a shadow over Lister's life, and this, together with the stress and anxiety of the war years, prevented its full fruition." He achieved much, but his untimely death has deprived the medical profession and the community at large of the greater gifts his original mind and wide experience were capable of yielding had he been spared.

Dr. A. T. Davies writes: "Lister was an accurate clinical observer and keen diagnostician and had an intuitive insight into the nature of disease. He possessed high intellectual qualities which he devoted unreservedly to the best interests of his profession and of his patients, indeed it is more than probable that his self-denying efforts and untiring devotion to his work at the Prince of Wales's Hospital for Officers intensified the beginnings of his long and fatal illness. He was a man who had friends and not acquaintances; his geniality of nature and kindness of disposition rendered him a genial host and companion."

Dr. Lister's death took place at Henley-on-Thames after a prolonged illness. He is survived by his widow, the only daughter of Eugen Ritter, and by two sons and a daughter.

MEASUREMENT OF ULTRA-VIOLET RADIATION.

To the Editor of THE LANCET.

SIR,—The standard colour-tubes of the acetone methylene-blue gauge for measuring ultra-violet rays, an account of which was published in THE LANCET of April 12th, 1924, were filled with graduated solutions of methylene-blue and water. Experience has shown that these fade with time and especially so in a warm climate. Mr. A. Webster has therefore made a new series of standards, using graduated pure copper nitrate solutions, and adding to the weaker ones of the series a certain amount of a solution of potassium chromate. These new standards have been matched against the grades of bleaching of our standard acetone methylene-blue solution exposed to light in our standard quartz tube, and these grades of bleaching in their turn have been standardised biologically against the time required for killing infusoria in a quartz cell and for producing erythema in a white skin. The new set of standards seem to work very satisfactorily and can be had of Messrs. Siebe Gorman, 187, Westminster Bridge-road, London, S.E.1, who supply the gauge in a convenient form. The utility of the gauge for measuring, not only dosage in light treatment, but also smoke pollution in cities, is illustrated by the following—from July 15th–20th the total ultra-violet reading was 78 at Peppard Common, Oxon., 60 at Hampstead, and 35 at the Meteorological Office, Kingsway, close to the Strand, London. The summer smoke-cloud thus robbed London of more than half its ultra-violet rays.

In making such measurements the quartz tube must be exposed in the vertical position on a roof with unrestricted view of the sky on all sides, or in an open space with such view, because far more ultra-violet rays come from the sky-shine than from the direct sunlight in the course of 24 hours. On bright summer days the tube requires changing twice and even thrice in the day, for the standard tubes only give 8° of the scale and the reading at Peppard in one day has been as high as 23. To measure smoke pollution one reading should be taken on a roof in the centre of the city and another in the country outside. To assist in the prevention of smoke pollution I would ask the medical officers of our cities to join in the taking of these observations and to send their measurements to me each month.

I am, Sir, yours faithfully,

LEONARD HILL.

INSULIN DOSAGE.

To the Editor of THE LANCET.

SIR,—I have read Prof. Murray Lyon's article on insulin in your issue of July 26th with great interest and appreciation, but I doubt if his plan of administering insulin two hours before meals will meet with general favour for several reasons.

In the first place, and very important, it is impracticable and inconvenient to give insulin as long as two hours before meals. It is no negligible hardship for a diabetic to have to get up two hours before breakfast to administer his dose. The nearer his life approximates to the normal the more likely he is to adhere strictly to his treatment and benefit from it.

Secondly, this plan seems unnecessary and sometimes even dangerous. Certainly there is little or no danger with the high fasting blood levels (0·2–0·3 per cent.) of Prof. Lyon's cases. But surely it is generally agreed that lower figures than these should be aimed at and can easily be obtained even in severe cases by less liberal diets of 1800 to 2100 calories (i.e., 30 cals. per kg. of body-weight) than the 2500–2800 calories (40 cals. per kg.) advocated by Prof. Lyon. 30 cals. per kg. is usually ample to meet the requirements of ordinary life and to maintain stable weight, because the body learns metabolic economy on such diets. The fasting blood-sugar can be kept more normal (0·12–0·15 per cent.) with less insulin and giving the dose half an hour before meals adequately controls glycosuria and prevents any but the slightest post-absorptive rise in blood-sugar if the dosage and the diet are properly balanced. It would be dangerous and unnecessary to give such a case insulin two hours before breakfast. With a diet liberal in carbohydrates or even total calories it is difficult or impossible to avoid fasting hyperglycæmia in severe cases with little endogenous insulin, as any excess of carbohydrate unburned by insulin is stored to reappear later in the blood when the effects of the dose wears off. Leaving aside the question of the bad effects of hyperglycæmia per se, such a plan requires more insulin to control even the glycosuria, and wide oscillations in the range of blood-sugar concentration must occur. In Fig. 2 Prof. Lyon hardly proves his point, for the observations cease two hours after breakfast with equal blood-sugars. True, he obtains lower blood-sugars before and immediately after breakfast, but the probability is that correspondingly higher figures would have been obtained in the afternoon when insulin was given two hours rather than half an hour before breakfast. Again, it would seem better to keep a case on a constant satisfactory balance of insulin and diet than to correct a "luxus" diet by cutting it down to half one day a week. The latter is an irksome complication in the diabetic's life and likely to lead to mistakes and hypoglycæmic symptoms.

I am glad to hear Prof. Lyon definitely state the variation he has found in batches of insulin. I have found the same in all the makes I have tried, though Lilley insulin seems to vary least in therapeutic action. This is serious enough from the therapeutic point of view, but still more so from the research standpoint, as it renders invalid any careful attempt in the last year to follow improvement or aggravation of insulin cases over long periods.

I am, Sir, yours faithfully,

R. D. LAWRENCE,
Chemical Pathologist, King's College Hospital.
August 1st, 1924.

the families concerned. Water-supplies and sinks are convenient and a large laundry provides ample facilities for washing purposes. Gas-stoves on the slot principle have been provided for cooking purposes.

Dr. Marion B. Andrews, the maternity and child welfare medical officer, reports a growth in the utilisation of home-helps, in the provision of dinners, and in the dental work. Where possible the provision of dinners for pregnant and nursing women is preferred, as being less likely to be diverted from its destined end than the issue of milk. The dinners are organised by the Infant Health Society, which, as Dr. Andrews tells us, is responsible for a great deal of valuable work. The rule is made that mothers pay £3 towards the cost of dentures, and it is pointed out that this charge is a serious obstacle for the mothers of families who are on the 'free-scale' in other respects. The limit of the 'free-scale' is a family income of 6*s.* per head, and, as Dr. Andrews puts it, the prospect of saving 60*s.* in a reasonable time on such an income is extremely remote. Nearly half the infant deaths were attributed to prematurity, and took place during the first fortnight of life. Dr. Andrews thinks these babies are usually washed and fed as normal children and some endeavours are now being made to meet their peculiar needs by stocking supplies of cotton-wool and olive oil for the use of the midwives. Classes for mothers have made progress, and the experiments of setting simple examination on mothercraft subjects has proved a success.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 26TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 52; scarlet fever, 1459; diphtheria, 670; enteric fever, 102; pneumonia, 457 (as against 570 of the previous week); puerperal fever, 38; cerebro-spinal fever, 9; acute polio-myelitis, 17; acute polio-encephalitis, 4; encephalitis lethargica, 69 (as against 81 of the previous week); dysentery, 4; ophthalmia neonatorum, 110. There were no cases of cholera, plague, or typhus notified during the week. Of the 52 cases of small-pox, 13 were notified from the county of Derby (Derby 2, Chesterfield 9, Chesterfield R.D. 1), 19 from the county of Northumberland (Ashington 18), 6 from the county of Nottingham (Hucknall 3, Mansfield 3), 2 from the county of Warwick (Coventry), 3 from Yorks, North Riding (Middlesbrough), and 9 from Yorks, West Riding (Rotherham C.B. 1, Rotherham R.D. 7). Of the cases of encephalitis lethargica, 8 were notified from the County of London (Bethnal Green 1, Deptford 1, Islington 1, Lambeth 1, Shoreditch 2, Stoke Newington 1, Woolwich 1), 5 from the county of Chester (Stockport 2), 2 from the county of Derby (Derby), 5 from the county of Durham, 3 from Essex (West Ham 2), 10 from the county of Lancaster (Manchester 4), 5 from the county of Stafford, 6 from the county of Warwick (Birmingham 3), and 5 from Yorks, West Riding (Sheffield).

Deaths.—In the aggregate of the great towns there was an increase of 12 in the total deaths. In London the number of deaths from all causes decreased from 750 to 729.

Royal East Sussex Hospital.—The year just ended in connexion with this institution at Hastings has been an anxious one. It has been marked by the removal from the old home to the present new institution, which was opened in November. A curtailment of its activities was necessitated for a time, during which there was a considerable falling off in the receipts from patients, and with a larger institution the larger had been the expenses without any increase in the income. The year was not a normal one, and the balance-sheet, which showed an excess of expenditure over income of £3524, cannot be accepted as a basis for the future. At the annual meeting on July 28th the governors, however, took a very wise step in adopting a suggestion which came from the mayor (Councillor Arthur Blackman) and appointed a committee to investigate the financial position. The findings of the committee will be watched with much interest by everyone interested in the administration of hospitals. It may be hoped that the committee will thoroughly thrash out the reason why the number of subscribers residing in Hastings and St. Leonards is out of all proportion to the size of the town.

Obituary.

THOMAS DAVID LISTER, C.B.E., M.D., B.S., M.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING PHYSICIAN, PRINCE OF WALES'S HOSPITAL FOR CONVALESCENT OFFICERS, MARYLEBONE, AND TO THE ASSOCIATION OF LOCAL GOVERNMENT OFFICERS.

We regret to announce the death on July 30th of Dr. T. D. Lister, whose work in connexion with tuberculosis and with life assurance problems was of high value. Born in London on Jan. 30th, 1869, the son of Francis Wilson Lister and Elizabeth Wishart, only daughter of David Roy, of Glasgow, he received his early education at the Haberdashers' Company School, entering Guy's Hospital, where he qualified with honours in 1892. He was house surgeon there and pathologist to the East London Hospital for Children, but did not remain on the staff of a general hospital. Later he became physician to the Mount Vernon Hospital for Consumption, consulting physician to the National Union of Teachers, to the Post Office Sanatorium Society, to the Association of Local Government Officers, and, for chest cases, to the Prince of Wales's Hospital for Officers at Marylebone. He was also a lecturer at the London School of Clinical Medicine. He was advisory physician to the National Sanatorium Association, a body concerned with the establishment and maintenance of sanatoria for workers suffering from tuberculosis, and as chairman of its sites and buildings subcommittee he drafted the scheme for the Benenden Sanatorium. He was an invited member of the panel committee of the County of London and of the Hospital Fund Board of Delegates.

Lister was a man of many interests and of great industry, and it was surprising to his friends how much valuable work he contrived to carry out. One side of his bent is shown by his undertaking to edit (1912) a new edition of Chavasse's popular Advice to a Mother. He possessed a keen, incisive, logical mind with a definite mathematical bias, which no doubt helped to determine his interest in the problems of life insurance and the industrial aspects of disease, more particularly of tuberculosis. In both of these subjects Lister was a recognised authority; indeed, one of the foremost, as his writings prove. Obituary.

THOMAS DAVID LISTER, C.B.E., M.D., B.S., M.R.C.P. Lond., F.R.C.S. Eng.,

CONSULTING PHYSICIAN, PRINCE OF WALES'S HOSPITAL FOR CONVALESCENT OFFICERS, MARYLEBONE, AND TO THE ASSOCIATION OF LOCAL GOVERNMENT OFFICERS.

We regret to announce the death on July 30th of Dr. T. D. Lister, whose work in connexion with tuberculosis and with life assurance problems was of high value. Born in London on Jan. 30th, 1869, the son of Francis Wilson Lister and Elizabeth Wishart, only daughter of David Roy, of Glasgow, he received his early education at the Haberdashers' Company School, entering Guy's Hospital, where he qualified with honours in 1892. He was house surgeon there and pathologist to the East London Hospital for Children, but did not remain on the staff of a general hospital. Later he became physician to the Mount Vernon Hospital for Consumption, consulting physician to the National Union of Teachers, to the Post Office Sanatorium Society, to the Association of Local Government Officers, and, for chest cases, to the Prince of Wales's Hospital for Officers at Marylebone. He was also a lecturer at the London School of Clinical Medicine. He was advisory physician to the National Sanatorium Association, a body concerned with the establishment and maintenance of sanatoria for workers suffering from tuberculosis, and as chairman of its sites and buildings subcommittee he drafted the scheme for the Benenden Sanatorium. He was an invited member of the panel committee of the County of London and of the Hospital Fund Board of Delegates.

Lister was a man of many interests and of great industry, and it was surprising to his friends how much valuable work he contrived to carry out. One side of his bent is shown by his undertaking to edit (1912) a new edition of Chavasse's popular Advice to a Mother. He possessed a keen, incisive, logical mind with a definite mathematical bias, which no doubt helped to determine his interest in the problems of life insurance and the industrial aspects of disease, more particularly of tuberculosis. In both of these subjects Lister was a recognised authority; indeed, one of the foremost, as his writings prove. With originality and real vision he possessed a deep fount of common sense, which combined to render his views both suggestive and practical. The mere list of his appointments affords a measure of his special experience of the problems of tuberculosis, more particularly as they affect the community. He was a trenchant critic of commonly accepted views where they were not supported by clear and logical evidence. Two books dealing with industrial tuberculosis (1910) and sanatoria for the people (1911) illustrate this point. Although he was on the staff of one sanatorium and helped to draw up the scheme for another, he saw the weak points in the institutional treatment of this disease and worked hard to suggest remedies for them.

Lister's knowledge of the problems of life assurance was profound. He was one of the chief medical officers of three insurance offices. It was characteristic of him that he was not content to study the medical problems of life assurance only, but that he also endeavoured to get a grasp of the actuarial and the business aspects of this important subject. His presidential address before the Assurance Medical Society on March 3rd, 1920, was a thoughtful, original, and suggestive essay, indicating numerous lines for future investigation and research. In it he developed an ingenious idea of vital trajectories. In 1921 he published a book on the Medical Examination for Life Assurance, a handy and conveniently arranged volume, which has been of the greatest service to those working in this branch of medical practice. It is likely long to remain a standard manual on this subject. Unfortunately his health gave way shortly after its publication. "There can be

years and found themselves at the age of 70 precluded from further participation in the benefits of the fund; and whether he could take steps to enable them to continue to participate especially in the cases of those ineligible for old age pensions.—Mr. Wheatley replied: The National Health Insurance Acts provide that the liability to pay contributions and the title to sickness and disablement benefits (but not to medical benefit) cease on an insured person attaining the age of 70, and I have no evidence that this feature of the scheme has been the cause of great dissatisfaction. The extension of sickness and disablement benefits to persons over 70, which could only be effected by amending legislation, would necessitate an increase in the weekly contributions, and would present serious administrative difficulties to approved societies in the application of the test of incapacity for work.

Kingston Vaccination Case.

Mr. Black asked the Minister of Health whether he would inquire into the costs claimed in the case brought by the Kingston vaccination officer against Mr. Barnet Marks, of St. Mark's Hill, Surbiton, for neglecting to have his child vaccinated, when the costs amounted to £1 11*s.* 6*d.*, compared with 6*s.* or 7*s.* in most similar cases brought by other vaccination officers; and whether he would see that the Kingston vaccination officer did not in future put vaccination defaulters to unnecessary expense in the matter of court costs.—Mr. Wheatley replied: I have inquired into this case, and am informed that the circumstances were unusual. I have no reason to believe that this vaccination officer puts defaulters to unnecessary expense in the matter of costs.

Local Authorities and Birth Control.

Mr. Thurtle asked the Minister of Health if he would consider the desirability of allowing local authorities to impart to people who wished to obtain it information as to birth control methods without penalising such local authorities by withdrawing their maternity and child welfare grants.—Mr. Wheatley replied: My view is that the institutions provided by local authorities at the cost of public funds should not be used for purposes such as that referred to in the question, which are the subject of controversy, without an express direction from Parliament.

Use of Pyridine in Methylated Spirit.

Mr. Lorimer asked the Chancellor of the Exchequer if, as methylated spirit was extensively used in surgery, and was one of the best sterilisers of the skin and of instruments, it had been brought to his notice that the addition of the new denaturant, pyridine, had a harmful effect upon the skin of the hands of surgeons and the skin of patients; and, if so, would he, in the interests of surgeons and patients, have the order to add pyridine to methylated spirit removed.—Mr. Graham (Financial Secretary to the Treasury) replied: The question raised by the hon. Member is at present under investigation.

THURSDAY, JULY 31ST.

Pensions Medical Officers and Overseas Service.

Lieut.-Colonel Fremantle asked the Minister of Pensions how many medical officers who had never served overseas were at present employed by the Ministry of Pensions among those serving on a whole-time agreement, including administrative officers, and among those serving on a sessional basis, respectively.—Mr. F. O. Roberts replied: 115 out of the 400 full-time medical officers, and 644 out of the 2408 sessional medical officers in the Ministry of Pensions did not serve overseas. I may add that nearly 94 per cent. of these medical officers have served either at home or abroad.

Lieut.-Colonel Fremantle asked the Minister of Pensions if he would state how many medical officers who have served overseas had been discharged from work under the Ministry of Pensions in the last six months in order to retain the services of doctors who had not served overseas.—Mr. F. O. Roberts replied: No medical officer with overseas service has been discharged in order to provide for another officer without overseas service. In selecting medical officers for discharge, which is unavoidable owing to the continued decline in the work of the Ministry of Pensions, full regard is paid to war service and to the qualifications required for the work to be performed.

Clothing for Sanatorium Patients.

Captain Elliot asked the Minister of Pensions whether any allowance was made for clothing for outdoor work for patients admitted to sanatoriums; and, if not, whether he would give instructions that such allowance should be made, since, in view of the current distress in many parts of the country, the provision of the necessary outfit imposed a serious charge upon the pensioner.—Mr. F. O. Roberts replied: The arrangements for the residential treatment of tuberculosis for both ex-Service men and others are in the hands of the local health authorities, subject to the general direction of the Ministry of Health. I understand that such treatment does not ordinarily involve any special expense to the patient. I may add, however, that if a pensioner desires to provide himself with additional clothing, arrangements have been made for the purchase of it by way of advance out of the personal allowance which accrues to the pensioner during his treatment.

Pensions for Tuberculous Patients.

Captain Elliot asked the Minister of Pensions whether the pensions for tuberculous patients were reduced after the discharge of the patient from the sanatorium for the second time to 40 per cent.; and whether he would give instructions that it should be 100 per cent. for six months as in the case of dismissal for the first time.—Mr. F. O. Roberts replied: There is no general rule in operation to the effect stated in the first part of the question. On discharge from a sanatorium for the second or any subsequent period of treatment a patient is given the pension at the rate of assessment which is found by a medical board to be appropriate to his condition, unless he is still eligible for the special rates of pension available for a certain period in cases of tuberculosis. These special rates of pension, which are at the rate of 100 per cent. for the six months after discharge following the first period of treatment in a sanatorium or training centre, and not less than 50 per cent. for the succeeding two years, were designed as a special measure for the assistance of cases in the earliest stages of the disease. Apart from the period of two and a half years in which these rates apply, cases of tuberculosis have to be dealt with under the general provisions of the warrant applicable to all classes of disability.

Treatment of Tuberculous Pensioners.

Captain Elliot asked the Minister of Pensions whether the tuberculous pensioners in parochial sanatoriums received treatment on the full scale laid down by the Pensions Ministry; and, if not, whether he would give instructions that additional allowances be given to pensions Ministry patients to bring them individually up to this scale.—Mr. F. O. Roberts replied: I am not quite clear what class of institution the hon. and gallant Member has in mind; but I may say that whenever a course of residential treatment is prescribed by a tuberculosis medical officer for a condition accepted by the Ministry as due to or aggravated by war service, and such treatment is given in a sanatorium approved by the Ministry of Health, the allowances and other expenses authorised under Article 6 of the Royal Warrant are granted.

Morbid Details of Condemned Prisoners.

Mr. Penny asked the Home Secretary whether, in view of the publication in the press of morbid details relating to prisoners under sentence of death in His Majesty's prisons, he would issue instructions that in the event of officials giving such information to the press they would be liable to instant dismissal.—Mr. Davies (Under Secretary for the Home Office). replied: Any such communication is strictly prohibited by statutory Rule 115 (1), which lays down that any breach will render an officer liable to dismissal.

Nursing Service in Mental Hospitals.

Mr. Hobhouse asked the Minister of Health whether the departmental committee appointed to consider in what direction the nursing service in mental hospitals could be improved had yet reported; and, if so, what recommendation had been made concerning the present excessive hours of duty worked by members of the staff in these hospitals.—Mr. Wheatley replied: The report is now in the hands of the printer, and will be published as soon as practicable.

National Health Insurance Commission.

Sir Kingsley Wood asked the Minister of Health when the Royal Commission on National Insurance would commence its sittings; and whether its proceedings would be open to the public.—Mr. Wheatley replied: The Royal Commission on National Health Insurance has already held a preliminary meeting and will commence its sittings for the hearing of evidence in October. I am informed that the Commission has not yet arrived at a decision as to the admission of the public to its meetings.

MONDAY, AUGUST 4TH.

Accommodation for Consumptive Prisoners.

Mr. Stranger asked the Home Secretary whether he was aware that in the metropolitan prisons there were insufficient cells set apart for offenders suffering from tuberculosis and that, in consequence, such offenders were put in ordinary cells; and whether prompt steps could be taken to improve the accommodation for those suffering from this disease.—Mr. Davies replied: At Wandsworth, Wormwood Scrubbs, and Holloway, the number of special cells for tuberculous patients is in excess of requirements. At Pentonville and Brixton the number of tuberculous cases is often somewhat larger than the number of special cells. When this occurs the cases are either located in adjoining ordinary cells or are removed to separate rooms in the hospital. In all cases alike the patient receives the appropriate treatment. It is, in fact, proposed to provide additional special cells without avoidable delay.

Indian Wool and Anthrax Infection.

Colonel PERKINS asked the Home Secretary whether he was satisfied that the provision of a disinfecting station at Liverpool was the best means of protecting British workers against infection from material which contained the germs of anthrax; and whether, seeing that this disinfecting station could not possibly protect dock workers handling such material, he would undertake to explore thoroughly the first means of protection suggested by general conference of the International Labour Organisation of the League of Nations, 1919—viz., the disinfection of material infected with anthrax spores in the country exporting such material. —Mr. HENDERSON replied: The Home Office has throughout been fully alive to the desirability of arranging, if practicable, for disinfection in the country of export; and with this object in view, immediately after the Home Office committee on anthrax reported in 1918, representations were made to the Government of India, from which country the greater part of the infected material comes. The Government of India, however, have not seen their way to arrange for disinfection in India, and we have therefore been thrown back on the alternative of providing for disinfection at the port of entry in this country. Under the arrangements in force at Liverpool the material is conveyed direct from the ship to the disinfecting station, so that the risk to the dock workers is reduced to a minimum.

TUESDAY, AUGUST 5TH

National Health Insurance Bill.

The National Health Insurance Bill, a consolidating measure which has already passed the House of Lords, went through Committee without amendment.

On the motion for the third reading,

Sir KINGSLEY WOOD congratulated the Government on getting this Bill through so expeditiously. It would be of considerable advantage to the approved societies.

Mr. GREENWOOD (Parliamentary Secretary to the Ministry of Health) said that the reason why the Bill was being pressed forward before the recess was on account of the regulations. It was the intention that the regulations should be completed in order to come into operation on Jan. 1st, 1925.

Lieut.-Colonel FREMANTLE said he wished to say from the point of view of medical men that this Consolidation Bill was of serious importance as regarded the efficiency of the operation of National Insurance. He trusted that the approved societies would realise more fully from this Bill what they could do under the law and what they had not already done. There were various measures of prevention which ought to be carried out, and he hoped that steps would be taken to bring these important preventive measures into operation in the interests of the health of the community.

The Bill was read a third time.

Workmen's Compensation (Silicosis) Bill.

Mr. R. DAVIES (Under Secretary to the Home Office) in moving the second reading of the Workmen's Compensation (Silicosis) Bill, which has passed through the House of Lords, said that under the existing scheme workmen's compensation could not be paid in cases where men were suffering from both silicosis and tuberculosis. This Bill proposed that compensation should be paid in such cases. It was an agreed measure. Medical men who had made a study of this problem had not been able to draw the line where silicosis ended and tuberculosis began.

Lieut.-Colonel FREMANTLE supported the Bill as a right and reasonable extension of the law in this connexion.

The Bill was read a second time.

PRINCE OF WALES'S HOSPITAL, TOTTENHAM.—Following upon the resignation of Mr. J. B. Banister from the post of gynæcologist to the Prince of Wales's Hospital on his appointment to the Charing Cross Hospital, the governors have invited Mr. Arthur Giles, consulting gynæcologist to the hospital, to resume active work on the staff as senior gynæcologist, and have appointed Mr. Aubrey Goodwin as gynæcologist.

DONATIONS AND BEQUESTS.—Mr. Lewis Loughor, a South Wales shipowner, has given £10,000 worth of Conversion Loan to the King Edward VII. Hospital, Cardiff.—Major Peake, of Bawtry Hall, chairman of the Airedale Collieries Company, has offered to the Castleford, Normanton, and District Cottage Hospital Committee £10,000 to build a ward in memory of his son, who was killed on the Somme.—By the will of the late Mr. Joseph Isaac Hallam, of Leicester, the testator left £1000 to the Leicester Infirmary for the endowment of a J. I. Hallam bed.—Lord Bearsted having offered to give £5000 to St. Thomas's Hospital funds on condition that four others give a similar amount, Mr. Frederick Lane has promised to be one of the four.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary quarterly Comitia of the College was held on July 31st. The President, Sir Humphry Rolleston, occupied the chair. The following were admitted to the Membership:—

Drs. Richard S. Allison, Walter R. Brain, Walter F. R. Castle, Alexander Cawadias, Philip C. P. Cloake, Keith D. Fairley, Charles B. S. Fuller, Eric F. Gartrell, Frank B. Hobbs, Charles J. Lewis, Samuel L. Ludbrook, Arthur A. Osman, Martin O. Raven, Carl I. Streich, Eric L. Susman, Geoffrey W. Theobald, and James G. Willmore.

Licences to practise Physic were granted to 208 candidates who had passed the required examinations after conforming to the by-laws and regulations.—Diplomas were granted, jointly with the Royal College of Surgeons of England, in the following subjects, to 31 candidates in Public Health, to 17 candidates in Tropical Medicine and Hygiene, to 5 candidates in Psychological Medicine, to 14 candidates in Ophthalmic Medicine and Surgery, and to 5 candidates in Laryngology and Otology. The names of the successful candidates are given below.

Mr. Norman William Smith was awarded the Murchison Scholarship.

On the nomination of the President, the Council and the Library Committee, the following College officers, members of committees, and examiners were elected for the ensuing year:—

Censors.—Dr. Horace George Turney, Dr. Edward Farquhar Buzzard, Dr. James Calvert, and Dr. Cyril Ogle.

Emeritus Treasurer.—Sir Dyce Duckworth.

Treasurer.—Dr. Sidney Philip Phillips.

Registrar.—Dr. Joseph Arderne Ormerod.

Harveian Librarian.—Dr. T. H. Arnold Chaplin.

Members of the Library Committee.—Dr. Frederick Parkes Weber, Dr. Herbert Spencer, Dr. William Cecil Bosanquet, and Dr. Charles Joseph Singer.

Curators of the Museum.—Dr. John Mitchell Bruce, Sir Seymour John Sharkey, Sir Frederick W. Andrewes, and Dr. William Hunter.

Finance Committee.—Dr. Raymond H. P. Crawfurd, Dr. Arthur George Phear, and Dr. Frederick John Poynton.

Examiners.—Chemistry: Mr. Charles Stanley Gibson and Dr. Robert Henry Aders Plimmer. Physics: Dr. William Edward Curtis and Dr. Sidney Russ. Practical Pharmacy: Dr. Alfred Ernest Russell, Dr. Edward Alfred Cockayne, Dr. Philip Hamill, Dr. Nathan Mutch, and Dr. Walter Ernest Dixon. Physiology: Dr. John Beresford Leathes and Dr. John Mellanby. Anatomy: Dr. Thomas Baillie Johnston. Medical Anatomy and Principles and Practice of Medicine: Dr. Herbert Morley Fletcher, Dr. Arthur Philip Beddard, Dr. William Cecil Bosanquet, Dr. James William Russell, Dr. Charles Richard Box, Sir James Purves-Stewart, Dr. Charles Bolton, Dr. Lewis Albert Smith, Sir John Charlton Briscoe, and Dr. James Aubrey Torrens. Midwifery and Diseases Peculiar to Women: Dr. John Prescott Hedley, Sir Ewen John Maclean, Dr. Thomas George Stevens, Dr. John Davis Barris, and Dr. Henry John Forbes Simson.

Public Health.—Part I.: Dr. Henry Wilson Hake. Part II.: Dr. David Samuel Davies.

Tropical Medicine.—Sir Percy William Bassett-Smith (Bacteriology), Sir Leonard Rogers (Diseases and Hygiene of the Tropics).

Ophthalmic Medicine and Surgery.—Dr. James Stansfield Collier.

Laryngology and Otology.—Sir StClair Thomson.

Psychological Medicine.—Part I.: Dr. Eric Danvers Macnamara. Part II.: Dr. Robert Percy Smith and Dr. C. M. Hinds Howell.

Communications were received from (1) Mr. C. F. Rey on behalf of His Highness Tafari Makonnen, the Regent of Ethiopia, expressing his appreciation of his visit to the College and sending a commemorative medal in memory of it. (2) The secretaries of the committee for the Study of Medical Hydrology in Great Britain (Drs. Edgecombe and Fortescue Fox), asking the support of the College for the aims and work of the Committee, and submitting certain representations on the subject which have been laid before the Ministry of Health. (3) The Home Office, asking the College to suggest names for filling a vacancy which has occurred, through the resignation of Sir Bryan Donkin, on the Advisory Committee on the administration of the Cruelty to Animals Act. (4) The University of Leeds asking the College to send representatives to the celebration of its coming of age and the jubilee of the Yorkshire College, Leeds.

The President brought before the College the results of communications with (1) the Home Office, concerning veronal. (2) The Ministry of Health, concerning heroin. A report, by Sir William Hale-White and Sir William Willcox, on the question of the prohibition or the limitation of the manufacture of heroin, was read. It was resolved on the recommendation of the Council that the Moxon medal be awarded to Sir Leonard Rogers. The Weber-Parkes prize and medal was awarded to Prof. Calmette.

Dr. Sidney Martin and Sir Arthur Newsholme were re-elected representatives on the Executive Committee of the Cancer Research Fund.

The President announced that he had appointed Sir Frederick Mott, F.R.S., to deliver the Harveian oration in 1925.

A report was received from the representative of the College on the General Medical Council.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At meetings of the Royal Colleges of Physicians and Surgeons on July 31st diplomas of L.R.C.P. and M.R.C.S. were conferred upon 208 candidates (188 men and 20 women) who have passed the Final Examination in Medicine, Surgery and Midwifery of the Conjoint Board, and have complied with the respective by-laws. The following are the names and medical schools of the successful candidates:—

H. E. Acheson, Royal Free; B. E. Ahrens, Cambridge and King's Coll.; N. J. Ainsworth, Middlesex; H. M. Allen, McGill; G. Anderton, St. Mary's; E. C. Archer, St. Thomas's; F. H. Armanious, Cairo and St. Thomas's; R. N. Aston and A. E. Austen, St. Bart.'s; J. M. Barnard, Charing Cross; E. V. Barnes, St. Thomas's; A. Barnsley, St. Bart.'s; J. C. Barrett, St. Thomas's; I. M. Benjamin, Guy's; T. P. Beswetherick, St. Thomas's; F. A. Bevan, St. Bart.'s; H. M. Bird, Middlesex; R. Bolton, St. Bart.'s; W. R. Bowen, Middlesex; A. D. Briscoe, Cambridge and St. Thomas's; Eileen M. Bronson, King's Coll.; A. C. Brown, Cambridge and St. Bart.'s; D. M. Brown, Birmingham; Doris D. Brown, Royal Free and St. Mary's; R. K. Bryce, London; H. F. Burtt, Birmingham; G. A. H. Buttle, Cambridge and Univ. Coll.; Doris M. E. Carrington, Birmingham; M. N. Chatterjee, Calcutta and Birmingham; F. E. Chester-Williams, St. Bart.'s; Edith I. Clark, Univ. Coll.; C. K. Colwill, Cambridge and Guy's; A. Cooke, Liverpool; H. A. Cooper, King's Coll.; J. D. Craig, Liverpool; S. H. Currie, London; D. D. R. Dale, St. Bart.'s; Agnes S. Daniel, Royal Free and St. Mary's; Edith M. Davies, Cardiff; J. Davies and Muriel Davies, Westminster; V. H. J. Davies, Charing Cross; S. C. Davison, Guy's; R. Y. Dawbarn, Liverpool; Ursula H. De Foubert, Royal Free; M. De Lacey, Cardiff and London; J. A. F. Denyssen, Cape and Guy's; D. M. de Silva, King's Coll.; A. C. Dick, St. Bart.'s; J. C. G. Dickinson, Guy's; C. P. Donnison, London; R. H. Dyer, Cambridge and King's Coll.; C. J. East and H. E. K. Eccles, St. Bart.'s; A. B. Eddowes, Cambridge and St. George's; J. E. Elam, Cambridge and St. Bart.'s; Dorothy K. Elliott, Birmingham; M. N. Emery, Basle and Univ. Coll.; Phyllis V. L. Epps, Royal Free; H. G. Estcourt, Middlesex; T. I. Evans, Cambridge and St. Thomas's; T. P. Evans, Charing Cross; A. Farid, Cairo and Guy's; D. W. G. Faris, London; C. W. S. Fernando, Univ. Coll.; W. W. J. Fernando, Middlesex; H. R. Fisher, Liverpool; F. G. France, St. Bart.'s; H. J. Fuller, Guy's; Florence M. Gamble, Royal Free; A. G. D. Gavin, Cambridge and St. Thomas's; W. T. M. Gentle, St. Mary's; W. H. Gervis, Cambridge and St. Thomas's; G. Gillett, Univ. Coll.; A. Glen, London; I. Gluckman, London; P. L. Goitein, St. Mary's; F. M. Graham, Madras and King's Coll.; P. L. Gray and W. H. Gray, Univ. Coll.; S. J. H. Griffiths, Bristol; G. E. Harries and J. Hartsilver, St. Bart.'s; H. Hinchco, Middlesex; R. C. Howard, St. George's; Dorothy M. Howse, Univ. Coll.; J. N. Hudson, Manchester; G. C. Hughes, Guy's; R. G. W. Husbands, Univ. Coll.; A. G. Hyde, Sheffield; M. H. Jacobs, Guy's; Bessie G. Jemson, London; C. M. Jennings, St. Bart.'s; A. J. R. F. Johnson, St. Thomas's; D. J. Jones, Cardiff and St. Thomas's; E. L. H. Jones, Leeds; R. W. Jones and R. C. Jones, Liverpool; A. Jowell, Cape and Guy's; D. E. Keefe, London; M. C. H. Kingdon, Cambridge and St. Mary's; I. Kinsler, A. H. Kynaston, and J. H. R. Laptain, St. Bart.'s; W. C. Latham, Liverpool; J. J. Laws and S. A. Leader, Guy's; H. Levit, Cape and Guy's; F. J. Levy, Guy's; Nancy R. Lewis, St. Mary's; E. M. Liddle, Manchester; W. R. A. Line, Birmingham; Rosalie E. Lucas, Bristol; H. J. McCarthy and J. McCunn, London; A. F. McGlashan, Cambridge and St. George's; G. A. McKaig, St. Thomas's; A. V. Mackenzie, Cambridge and St. Bart.'s; R. S. MacLatchy, Dalhousie and London; J. R. Maleri, Punjab and St. George's; H. B. Mann, Cape and Middlesex; R. G. B. Marsh, St. Thomas's; D. J. Martin, London; F. Martin and G. A. Martin, Guy's; R. Massingham, Univ. Coll.; J. H. Matthews, Manchester; L. M. Maybury, Cambridge and Univ. Coll.; B. A. J. Mayo, St. Bart.'s; T. F. Meyrick, King's Coll.; K. V. Milburn, Durham; W. J. Montague, Cambridge and Guy's; J. H. Moore and J. G. Morgan, Univ. Coll.; L. Morris, Manchester; C. J. Murphy, Birmingham; J. W. Nankivell, Middlesex; M. C. O'Connor, St. George's; J. O. Oliver, St. Thomas's; F. C. O'Mara, Liverpool; Helen E. D. E. Ornstein, King's Coll.; K. C. L. Paddle, St. Bart.'s; L. J. Panting, Cambridge and Middlesex; H. R. Paterson, Cambridge and St. Thomas's; Dorothy E. Peake, London; A. A. F. Peel, Oxford and St. Bart.'s; M. S. Pembrey, St. Bart.'s; D. B. Phillips and L. M. J. R. Pilot, St. Thomas's; G. H. Pitt, Guy's; L. Platzky, Cape and Middlesex; H. G. Poles, Charing Cross; A. Pool, Liverpool; Gwendolen M. Pratt, Royal Free; J. O. Priestley, Middlesex; V. J. Rao, London; W. E. Rees, St. Thomas's; H. D. C. Rice, Cambridge and King's Coll.; Jessie L. Robb, Birmingham; W. A. Robb, St. Bart.'s; Lilian E. Robinson, Univ. Coll.; W. E. Rodgers, Madras and London; G. R. Rolston, London; F. W. Roques, Cambridge and Middlesex; E. Scott and J. A. Scott, Liverpool; S. J. Scurlock, London; E. K. Seab, Hong-Kong and King's Coll.; J. Sellick, Guy's; A. Shirley, Cambridge and St. Thomas's; A. D. H. Simpson, St. Bart.'s; A. W. H. Smith, Cardiff and St. Bart.'s; Jean L. Smith, Cardiff and Charing Cross; K. S. M. Smith, St. Bart.'s; J. F. Southward, Bristol; H. L. Sparrow, Cambridge and King's Coll.; C. E. Stainthorpe, Durham; E. V. Suckling, London; F. S. Tait, Birmingham; C. Thomas, London; D. M. E. Thomas, St. Mary's; O. F. Thomas, Manchester; O. O. S. Thomas, St. Mary's; W. D. R. Thompson, St. Thomas's; D. S. Todd-White, Guy's; G. M. Tothill, Charing Cross; J. R. Tree, Middlesex; L. A. S. Trott, Guy's; C. A. Van Rooyen, Ceylon and London; G. C. Vaughan, Birmingham and London; I. R. Vermooten, Guy's; F. O. Walker, Middlesex; J. L. le C. Walker, Guy's; H. A. Ware, Cambridge and St. Bart.'s; H. C. Warner, Guy's; R. L. Washington, Birmingham; H. O. Watkins-Pitchford, St. Thomas's; A. Watson, St. Mary's; B. M. R. West, Middlesex; V. E. Whitman, Cardiff; Mary A. Wiles, King's Coll.; W. Wilkinson, St. Bart.'s; R. G. Williams, Guy's; V. G. Williams, Birmingham; T. J. Wilson, Alberta and St. Bart.'s; W. M. Winder, St. Mary's; A. J. Wrigley, St. Thomas's; and E. Zimmerli, St. Mary's.

The undermentioned diplomas were also conferred upon the following candidates:—

Diploma in Ophthalmic Medicine and Surgery.—G. A. Thomas, H. M. Armstrong, B. Basu, W. J. Chapman, J. M. Damany, G. Kumar, S. H. Miles, E. V. Oulton, Freda Ramsay, J. Rego, R. S. Shah, S. S. Sumner, K. N. Tabdon, and H. E. Variava.

Diploma in Tropical Medicine and Hygiene.—E. Benjamin, R. G. Cochrane, T Creaser, P. K. Dixon, W. Dunlop, R. J. Gittins, A. W. Grace, M. L. C. Irvine, R. B. MacGregor, H. G. D. Mathur, Dorothy Mitchell, S. Nag, G. C. Ramsay, Beatrice A. S. Russell, Ruth M. Scutt, H. W. Torrance, and B. B. Yodh.

Diploma in Laryngology and Otology.—Walter R. Beavis, John B. Cavenagh, John Hare, Humphrey I. Marriner, and Thomas G. Wynne.

Diploma in Psychological Medicine.—John S. Harris, William J. T. Kimber, Neil Macleod, Ernest G. T. Poynder, and David Slight.

Diploma in Public Health.—Henry L. Barker, Joyce R. Batten, William G. Booth, Lionel P. Costobadie, Andrew Crawford, Barjor Bamanji Dalal, Edith M. P. Davies, Sidney R. E. Davies, Helen M. Du Buisson, Mary Esslemont, Gwladys Evans, Dorothy J. L. Gallie, Percy C. C. Garnham, George McN. Hargreaves, Marjorie C. Hawkins, Naunton R. Jenkins, Elspeth H. R. Livingstone, Victor A. Luna, Kathleen F. Matthews, Alice D. Pocock, Abraham T. W. Powell, Ivor N. O. Price, Violet Reade, Grace Stevenson, Emma M. Store, Edward Tagoe, Blanchette Thomas, Percy Thwaites, Edgar H. Wilkins, Gwendolen Wilson, and John G. Wilson.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were successful in the undermentioned subjects:—

Surgery.—W. B. Arnold, St. George's Hosp.; and K. R. Chaudhri, C. E. Donaldson, and R. Hare, St. Mary's Hosp.

Medicine.—H. P. Burns, St. Mary's Hosp.; and J. C. C. Langford and H. Morris (Sect. I.), St. Bart.'s Hosp.

Forensic Medicine.—J. O. W. Bland, St. George's Hosp.; and J. C. C. Langford, St. Bart.'s Hosp.

Midwifery.—H. L. Bernstein and J. L. Hopkins, Guy's Hosp.; G. L. W. Iredale, Edinburgh and St. Mary's Hosp.; and J. de V. Maingard, Guy's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: W. B. Arnold, H. P. Burns, K. R. Chaudhri, C. E. Donaldson, and R. Hare.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates have passed the Triple Qualification Examination:—

FINAL EXAMINATION.

Amy B. R. A. Perriton, Alexander H. Forman, Montague A. Watson, Edward N. Jamieson, Matthew M. Tannahill, Charles C. Robson, Vellathusseri Chakalakumbil Govinda Menon, Patrick Murray, Harold V. Ritchie-McKinlay, Cyril F. Deutrom, William A. Ekanayake, Samuel B. Jones, Harmanis Amarasinghe, Mary C. Semple, James Donnelly, Oliver H. D. Oliver, Sinnatamby Thambipillai, Archibald Menzies, Robert S. Caldwell, Myer Goldberg, Edward S. Greaves, James H. MacAlpine, Sudhindra Nath Bandyapadhay, James M. Anderson, Simon Levenson, Arthur E. Coyne, James G. O'Keeffe, Darwish Moustafa Safwat, Joseph F. Sweeney, George M. Rose, Daniel T. Gemmell, Charles Campbell, Vernon Bell, Donald M. Gray, David R. Paterson, and Hillel Schulgasser.

Medicine.—Bentis Silva Jayawardena, Fakherddin El-Ahmadi, Nashid Tadros Yusif, Henry A. Newton, Herman H. James, Norman Wren, George H. Tarras, Percy A. M. Jayewardene, Joseph E. Israel, Thomas J. Muir, and Naranapillai Ampalavanar.

Surgery.—Bentis Silva Jayawardena, Mollie F. Churcher, Herman H. James, James Kirkness, George H. Tarras, Arcot Vasudev, Eric S. Brohier, David Stewart, John Ponnambalam Subramamiam, and Naranapillai Ampalavanar.

Midwifery.—Ebenezer A. M. McKinney, Patrick Groarke, Tom G. S. Harkness, Fakherddin El-Ahmadi, John T. Smith, David S. Middleton, Mollie F. Churcher, Norman Wren, Richard F. Pagnam, James M. Rutherford, Joseph E. Israel, Victor B. van Dort, Eric S. Brohier, and David Stewart.

Medical Jurisprudence.—Winifred G. Price, Douglas B. Cruickshank, Carapiet Aviet Basil, Thomas W. Chapman, Frederick Blacklee, Alastair G. Cruikshank, James F. Wallace, Henry B. Martin, George McCracken, William J. Ledgerwood, John B. Hutchison, William W. Crawford, John Lees, Philip Henry, Isaac Michaelson, Eliza Bell, James T. M. Symington, Horace S. Kent, John C. Shiach, Jessie R. Bruce, Alexander F. Chisholm, Ernest G. Douglas, Thomas M. Ormiston, John M. Coutts, George B. Burnett, Catherine Millar, Arthur A. F. Shepherd, Douglas B. Craig, James W. Wylie, Thomas D. Gould, Robert J. Snodgrass, Alexander J. M. Gall, Cassaly Ismail, and John A. Hyde.

University of London.—The following elections have been made at University College, London:—Sharpey Research Scholarship in Physiology: Mr. Richard J. Lythgoe, of the Mercers' School, Trinity College, Cambridge, and University College Hospital Medical School. Percy F. MacGregor Scholarship in Embryology: Mr. G. Payling Wright, of University College School, Hampstead, Exeter College, Oxford, and University College Hospital Medical School.

University of London Unionist Association.—At a meeting of the Association held on July 30th, on the proposal of Sir Philip Magnus, and seconded by Dr. Walter W. Seton, Sir John Rose Bradford, K.C.M.G., C.B., C.B.E., M.D., D.Sc. Lond., F.R.S., was adopted as the official Conservative candidate in the by-election caused by the death of Sir Sydney Russell-Wells, in which polling has been postponed until after the University vacation. Sir John Rose Bradford is a distinguished graduate of the University of London, has been a member of the Senate, and is consulting physician to University College Hospital. In his wider interests as secretary of the Royal Society for seven years prior to the war, consulting physician to the British Expeditionary Force in France, and by numerous scientific works he has earned great esteem. He is opposed to the suggested appointment of a Statutory Commission to carry out the recommendations of the "Haldane Commission," and can be relied upon to safeguard and promote the best interests of the University and its graduates.

Metropolitan Hospital Sunday Fund.—Of the total of £84,000 raised for this Fund by this year's collection, the sum of £83,000 has been distributed to date by the Distribution Committee among 218 London institutions. Awards have been made to 18 London general hospitals, varying in amount from £8110 (London Hospital) to £1170 (Seamen's Hospital), to the total of £47,265, and grants were made to a number of special hospitals, including Queen's (for children), £2000; Hospital for Sick Children, Great Ormond-street, £1780; East London, £1200; Victoria (Chelsea), £1100; National (for paralysis), £1000; Royal London Ophthalmic, £1000; Royal National Orthopædic, £1050; City of London (chest) Victoria Park, £920; Brompton (consumption), £750; and Middlesex (cancer wing), £560. Numerous contributions were made to convalescent homes, cottage hospitals, dispensaries, and nursing associations.

Fellowship of Medicine and Post-Graduate Medical Association.—From August 18th to Sept. 8th there will be a special course in the diagnosis and treatment of common diseases of the nervous system at the West End Hospital for Nervous Diseases. The course will take place at the out-patient department of the hospital situated at 73, Welbeck-street, W. 1, and will consist of lectures, clinical demonstrations on selected cases, &c. During the month of September the following courses will be held: a fortnight's intensive course in medicine, surgery, and the special and other departments at the Westminster Hospital; on dermatology at the Hospital for Diseases of the Skin (Blackfriars); on diseases of infants at the Infants' Hospital; on ophthalmology at the Royal Westminster Ophthalmic Hospital; and on psychological medicine at the Bethlem Royal Hospital. Copies of each syllabus of the August courses, together with the monthly Bulletin, may be had on application to the secretary at 1, Wimpole-street, London, W. 1.

North Devon Children's Convalescent Home, Lynton.—On July 28th this home at Lynton, which has 25 beds and cots for children, was opened by the Earl of Portsmouth. The building, including extension grounds, is the gift of Mr. Robert Living, who has guaranteed a certain sum towards its maintenance. The upkeep is dependent on voluntary contributions, and subscribers have a right to nominate children for a week or so in the home. The home is intended as a general convalescent children's home for non-infectious cases, and special arrangements are being made to deal with surgical tuberculosis.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, August 11th.—11 a.m., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 p.m., Dr. Scott Pinchin: Medical Out-patients.

Tuesday.—11 a.m., Dr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 p.m., Mr. Sinclair: Surgical Out-patients.

Wednesday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 11 a.m., Medical Registrar: Medical Wards. 2.30 p.m., Mr. Donald Armour: Surgical Wards.

Thursday.—10 a.m., Dr. Grainger Stewart: Neurological Department. 12 noon, Dr. Scott Pinchin: Diseases of the Heart.

Friday.—11 a.m., Mr. Simson: Gynæcological Demonstration. 12 noon, Surgical Registrar: Surgical Pathology. 2 p.m., Dr. Burrell: Medical Out-patients.

Saturday.—9.30 a.m., Dr. Burnford: Bacterial Therapy Department. 10 a.m., Dr. Saunders: Medical Diseases of Children. 10 a.m., Mr. Banks Davis: Operations of the Throat, Nose, and Ear.

Daily 10 a.m. to 6 p.m., Saturday 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W. 1.

Monday, August 11th, to Saturday, August 16th.—Hospital for Consumption and Diseases of the Chest, Brompton. Mon., 10 a.m., Dr. Burrell: Artificial Pneumothorax and Fluid Replacement. 12 noon, Dr. Inman: Immunity in Relation to Diagnosis and Treatment in Pulmonary Tuberculosis. 2 p.m., Dr. Melville: Dem. in X Ray Department. Tues., 10 a.m., Dr. Punch: The Complement-Fixation Test in Pulmonary Tuberculosis. 12 noon, Dr. Davidson: Dem. of Non-Tuberculous Cases. 2 p.m., Sir James Dundas-Grant: Throat Cases. Wed., 10.30 a.m., Mr. Tudor Edwards: Operations. 2 p.m., Dr. Wall: Dem. in Wards. 3 p.m., Dr. Gosse: The Electrocardiograph and its Uses. Thurs., 10 a.m., Dr. Burrell: Vital Capacity in Diseases of the Chest. 12 noon, Dr. Beaumont: Dem. of Advanced Cases. Fri., 10 a.m., Dr. Davidson: Artificial Pneumothorax. 2 p.m., Mr. Roberts: Operations. Sat., Dr. Batty Shaw: Demonstration of Cases.—Queen's Hospital for Children, Hackney-road. Mon., 10 a.m., Mr. Broster: Cases Illustrating General Surgery. 5 p.m., Dr. Hewer: Anæsthesia in Children. Tues., 10 a.m., Mr. Todd: Lecture-Demonstration—Cases Illustrating Treatment of Injuries to the Elbow. 2 p.m., Dr. King: Medical Cases. Wed., 10 a.m., Mr. Todd: Lecture-Dem. Common Fractures in Children. Thurs., Dr. Winnicott: Medical Cases. 2 p.m., Mr. Whitchurch Howell: Demonstration of Surgical Cases, chiefly Orthopædic. Fri., 10 a.m., Mr. Broster: Cases Illustrating General Surgery. 4 p.m., Mr. Whitchurch Howell: Lecture-Dem.: The Importance of Detail in Orthopædic Surgery. Sat., 10 a.m., Mr. Whitchurch Howell: Operations and Demonstrations.

Appointments.

Edwards, Miss K. St.V., M.B., B.S. Lond., has been appointed Medical Officer of the Surgical Department, Glanely Sanatorium, S. Wales.

Higson, W. D., M.B., Ch.B. Liverp., Medical Officer of Maidstone Gaol.

Lawrence, R. D., M.D. Aberd., Chemical Pathologist and Lecturer in Chemical Pathology, King's College Hospital.

MacCallan, A. F., C.B.E., M.D., Camb., F.R.C.S. Eng., late Director of Ophthalmic Hospitals in Egypt, to be a Consulting Ophthalmic Surgeon to the Cassel Hospital for Functional Nervous Disorders.

Shepherd, W. M., M.D. Edin., F.R.C.S. Edin., to be an additional Medical Referee under the Workmen's Compensation Act for the Districts of the Doncaster and East Retford County Courts.

Hampstead General and North-West London Hospital: Gray, A. O., F.R.C.S. Eng., M.R.C.P. Lond., Gynæcologist; Hodgson, H. G., M.B., B.S. Durh., D.M.R.E. Camb., Radiologist; Stobo, A., M.B., Ch.M. Sydney, House Physician; Dick, B. M., M.B., Ch.B. Edin., House Surgeon; Bradley, R., M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S. Eng., Casualty Medical Officer; Hayward, M. F., M.B., B.S. Lond., Casualty Surgical Officer.

Manchester Royal Infirmary: Brockbank, W., M.R.C.S., L.R.C.P., Resident Medical Officer, Barnes Convalescent Hospital, Cheadle: Galloway, R. L., M.B., Ch.B. Edin., Senior Surgical Registrar; Scotson, F. H., F.R.C.S., Second Surgical Registrar.

Certifying Surgeons under the Factory and Workshop Acts: Armstrong, C. W., L.R.C.P. Lond., M.R.C.S. (Castleton); Emmett, R. H., L.R.C.P. Lond., M.R.C.S. (Portsmouth).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, District Infirmary and Children's Hospital.—Hon. M.O.
Barnstaple, North Devon Infirmary.—H.S. £150.
Birkenhead Education Committee.—Asst. M.O. £600
Blackpool, Victoria Hospital.—Asst. H.S.
Brighton, New Sussex Hospital.—H.S. £50.
Brighton, Royal Sussex County Hospital.—H.S. £150.
Carlisle, Cumberland Infirmary.—Res. M.O. £175.
City of London Hospital for Diseases of the Heart, Victoria Park, E.C.—Half-time M.O. £200.
East Ham County Borough.—Asst. M.O. £600.
Gloucestershire Royal Infirmary, Gloucester.—Asst. P. and Pathologist.
Greek Refugees, Macedonia.—M.O. £350.
Hertfordshire County Council.—School Dentist. £500.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—H.P. £100.
Kent Education Committee.—School Dentist. £504 14s.
Leeds Township Infirmary.—Asst. M.O. £275.
Leicester Royal Infirmary.—Second Res. Anæs. £200.
Melbourne University, Victoria, Australia.—Chair of Pathology. £1200.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. M.O. £250.
Otago University, New Zealand.—Prof. of Surgery. £600.
Pontypridd Union, Llwynypia Hospital.—Sup. M.O. £700.
Royal Devon and Exeter Hospital.—Asst. P.
Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. £100.
Sherwood Forest, Notts, Ransom Sanatorium.—Asst. R.M.O. £375.
Shrewsbury, Royal Salop Infirmary.—H.P. £160.
Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. £150.
Staffordshire Education Committee.—Asst. Sch. Med. Insp. £600.
Stockport Infirmary.—Third Res. H.S. £175.
Tunbridge Wells General Hospital.—H.S. £160.
West Ham County Borough.—M.O.H. and Chief Sch. M.O. £1500.
Whittingham, Preston, Lancs, County Mental Hospital.—Locum Tenens M.O. £8 8s. per week.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Uckfield, Sussex.

The Secretary of State for the Home Department gives notice that he proposes to appoint another Surgeon as an additional Medical Referee under the Workmen's Compensation Act, 1906, for the districts of the Gateshead, Hexham, and Bellingham, Morpeth and Blyth, Newcastle-upon-Tyne, North Shields, and South Shields and Jarrow County Courts (Circuit No. 1). Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than August 23rd, 1924.

The Secretary of State for the Home Department gives notice that in consequence of the death of Mr. A. Benthall, one of the Medical Referees under the Workmen's Compensation Act, 1906, a fresh appointment or appointments have to be made in respect of the districts of the following County Courts: Uxbridge (Circuit No. 34); Croydon and Epsom (Circuit No. 45); and Brentford (Circuit No. 46). Applications should be addressed to the Private Secretary, Home Office, and should reach him not later than August 23rd, 1924.

Births, Marriages, and Deaths.

BIRTHS.

HICKINBOTHAM.—On July 26th, at Colchester, the wife of J. R. Hickinbotham, M.B., of a son.

PANTON.—On July 30th, at Solihull, Warwickshire, the wife of Major H. F. Panton, R.A.M.C., of a daughter.

MARRIAGES.

ROWELL—SCOTT.—On July 30th, at St. Mary's, Nether Alderley, Major W. H. Rowell, O.B.E., M.D. (late R.A.M.C.), to Sarah, elder daughter of Edward Scott, Esq., Rookwood, Alderley Edge.

DEATHS.

COOPER.—On July 30th, at a nursing home, Ernest Frederic Cooper, M.R.C.S., L.R.C.P.

VEALE.—On July 30th, in London, Major Philip John Veale, M.D., I.M.S.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ROYAL GWENT HOSPITAL, NEWPORT, MON.—On August 4th a new wing of the hospital was opened by Lord Tredegar. The wing was erected at a cost of £80,000, and is part of an extension scheme which will cost £240,000, to which £13,000 have already been contributed by colliery and other workmen.

Notes, Comments, and Abstracts.

HOW TO POPULARISE CREMATION.

ALTHOUGH the disposal of the dead by cremation has developed in England during the last fifty years to such an extent that it has now become almost an every-day occurrence, the fact remains that it has obtained no marked preference amongst the larger proportion of the people. Fifty years ago the Cremation Society was formed in the interests and for the welfare of the living, to promote a movement towards a more sanitary and economic and æsthetic method of disposal of the dead than is effected by earth burial, and on August 1st the third annual conference of cremation authorities was held at the Conference Hall of the British Empire Exhibition at Wembley. Sir Thomas Horder, who occupied the chair at the invitation of the Rt. Rev. Bishop Charles Gore, said that the problem which remained to be solved was to find the means of popularising cremation, as at present it was too much confined only to the more thoughtful and more imaginative members of the community. Our cemeteries, he said, increasing yearly in number and size, hem in the urban dwellers and disfigure the landscape, and as yet neither our civilisation nor our culture have found an equally satisfactory and popular solution of the difficulty. Propaganda might take place along three lines. In the first place, from the sanitary aspect, the advantages of cremation were obvious enough to all thinking medical men and even laymen, but such an argument would hardly stir the popular imagination, as the progress of any reform which touched a traditional sentiment must always be slow. In the second place, an appeal on the ground of economy might be more successful, but was more likely to influence local authorities than the general public. In the third place, he said, the strongest appeal might be made from the sentimental and æsthetic point of view, and, to do this, it was necessary to demonstrate that cremation could be invested and surrounded by religious and sentimental ideas which were quite as deep and inspiring as those which attended the ceremony of earth burial. Bishop Gore dealt with the prejudice against cremation that was felt by a great many people and arose from the conception that there was a resurrection of the dead by the re-collection of the material atoms and elements of the dead body at the end of the world. What he was glad to tell people haunted by that sort of theological scruple was that even in the earlier days of Christianity there were people like St. Paul, who stoutly maintained that it was an impossible and unintelligent conception. In the Nicene creed instead of "I believe in the resurrection of the *flesh*" or "the resurrection of the *body*," the phrase was "the resurrection of the *dead*." Such scruple, therefore, was no part of the Christian creed, and in any case it had no bearing on the question of cremation as opposed to burial, because cremation only did more rapidly what in any case ultimately occurred. While the Roman Catholic Church still prohibited cremation, it did not do so on theological grounds but out of deference for past custom. If, he concluded, the practical advantages of cremation were properly considered, within a measurable time this method might be widely applied to the national advantage.

PUBLIC HEALTH IN MAURITIUS.*

THE estimated population of Mauritius on Dec. 31st, 1921, was 376,314, and 377,594 on the corresponding date in 1922. The birth-rate in 1922 was 37·0 per 1000, as compared with an average of 36·2 for the quinquennium, 1918-22. In the several districts the ratio varied from 26·6 in Black River to 43·4 in Moka. The death-rate was 34·5, a distinct improvement on the quinquennial average of 42·0 per 1000. The district variations ranged from 23·8 in Plaines Wilhems to 40·8 in Grand Port and 42·6 in Port Louis. (These are crude rates, including deaths of persons arriving from other districts.) The *infantile mortality* was 147·9 per 1000 births, as compared with 179·7 in the previous year. The chief cause was "congenital debility." Dr. T. B. Gilchrist, Director of the Medical and Health Department of the colony, who presents the report, states that unfortunately registration of stillbirths is not compulsory, and the total number probably greatly exceeds the number registered (1678). Venereal disease and congenital causes accounted for the majority. Owing to early marriages amongst Indians, and bearing of children at an immature age, as well as hardships and privations among the lower classes, many children are born in a weak state. Twenty midwives have been trained and placed on the sugar estates, but no township except Port Louis possesses a qualified midwife, which is "a deplorable state of affairs." A Midwifery and Child

---

* Report on the Medical and Health Department, 1922. Port Louis.

Welfare Society was started, but "unfortunately the ladies got disheartened from want of financial support, and the society is at present dormant."

Hospitals and Dispensaries.

At the various hospitals and dispensaries 111,466 cases of illness were treated during the year under review, a considerable advance on the quinquennial average of 96,808. The admissions to hospital for *malaria*, including those for enlarged spleen, numbered 2762, and in addition 30,897 cases were treated in the various public dispensaries. A spleen census was carried out among 14,659 school-children, in 15·8 per cent. of whom enlargement was detected. No examination was carried out in the districts of Grand Port, Savanne, Black River, or Plaines Wilhems; in the other five districts the percentage of enlargement varied from 4·6 in Moka to 20·8 in Port Louis and 21·3 in Flacq. The bionomics of *Anopheles costalis* were investigated by Mr. Malcolm MacGregor during eight months of the year under report[1]. It was found that *A. costalis*, *A. maculipennis*, and *A. funestus* were present, the first named being the chief agent for the spread of malaria in the island. Breeding places were found up to 1200 ft. *A. maculipennis* occurs extensively in Port Louis and along the coastal belt below 500 ft. altitude. *A. funestus* was found up to 500 ft. A large amount of antimalarial work was carried out in the construction of drains, destruction of mosquito-breeding places, clearance of marshes, &c. There were 224 notifications of *enteric fever*, of which 106 were in Port Louis. Of the total cases 158 were notified in the six months, February to July; and of those in Port Louis 98 in this period. Dr. Gilchrist states that the difficulties experienced by his department "have been accentuated by the fact that medical practitioners in many cases do not notify the disease until the patient has either recovered or died, and then only for purposes of having the premises disinfected. . . . Such late notification and existing conditions prevent the Medical and Health Department from combating the disease in a prompt manner." Such remissness is inexcusable, and indeed inexplicable. Absence of proper latrine accommodation, pollution of the Grand River water-supply, and prevalence of flies are the chief factors in the enteric incidence.

Leprosy, Plague, &c.

With regard to *leprosy*, this disease is not classified in Mauritius as infectious, and therefore is not notifiable; lepers are not segregated. Dr. Gilchrist, however, states "That leprosy is a contagious disease is certain, and I strongly urge that leprosy be made notifiable." The Powder Mill Leper Hospital is now completed, and "every inducement should be made to get all pauper lepers who are receiving Government relief to enter that institution, and if necessary, to compel them to do so, and supervision of contact of well-known lepers should be provided for." No allusion is made to the fish-diet theory of causation, or to the probability of transmission by bites of insects.

Plague is endemic in Mauritius. In 1899 there were 919 cases, and in 1903, 978 cases. During 1922 the cases reported numbered 98, as compared with 375 in the previous year. Of these 98 cases, 65 occurred in Port Louis and 26 in Plaines Wilhems district; 75 were fatal. From February to August no plague was reported, except 3 cases in Plaines Wilhems (February), and 3 in Port Louis (August); no plague bacilli were found in rats from Feb. 13th to July 30th. Iodine given intravenously was found to be the most successful treatment; the dose is not stated. The mortality from *pulmonary tuberculosis* was 1076, and for all forms of tuberculosis 1083, as compared with 1027 and 1071, the quinquennial averages. There has been no *small-pox* in the island since 1913; 10,140 children were vaccinated, being 76·60 per cent. of the total births. "The danger of an unvaccinated population is not realised until an epidemic of small-pox occurs."

The Cleansing Campaign.

Dr. J. Balfour Kirk, M.O.H. for Port Louis, arrived in the colony in September, 1922, and refers to the cleansing campaign carried out by Dr. Gilchrist, "which was a complete success, and for the first time in their lives the inhabitants were able to see in their own streets and yards a condition which would be a credit to any city in the world." The disposal of nightsoil is, however, "uniformly unsatisfactory." The water-supply from Grand River and the Bathurst and Dayot canals is also bad, and improvement in this direction is the most urgent sanitary reform required. "The housing problem in Port Louis is acute." Improvements are, however, being made, and when the new buildings are completed the slum property will be closed for human habitation. With regard to food-supply the position is most unsatisfactory. "Legal power to control the quality of food and drugs is practically non-existent. . . The milk trade in Port Louis is in as corrupt a state as it is possible to be in." Of 276 samples examined 52 per cent. were sophisticated; also 79,656 lb. of fish, 13,320 lb. of flour, and 2430 lb. of margarine were seized and disposed of by dumping.

School medical inspection was started in Port Louis during the year, ten schools being visited, and the number of children examined being 1189. The chief diseases notified were ankylostomiasis (439), malaria (237) and bad teeth (148). Dr. Keisler notes that the water-supply is defective; it is obtained either from the Grand River Northwest reservoir or the Bathurst Canal. These waters are far from pure, and no filters are used. The accommodation is inadequate in the great majority of schools, and the desks and seats "of the ancient type, tending to malformation of the spine and chest, and their arrangement as regards light is in many instances defective."

"THERMAL ANAPHYLAXIS."

WE have received from Dr. Henri Médawar, of Vichy, a little pamphlet in which he describes the treatment of a series of persons, who were intolerant of one of the Vichy waters, by means of daily subcutaneous doses of the same water. He believes that individuals of an arthritic diathesis, to whom this water is obnoxious, when so treated may acquire tolerance of large and adequate doses. Such observations, if supported, appear to favour the hypothesis that the well-known disturbances which medicinal waters (in themselves colloidal suspensions) set up in sensitive subjects may be due really to slight forms of colloidal shock. Minute doses of the same water would appear to effect the desensitisation of these subjects.

THE PREVENTION OF FIRE.

Dr. F. J. Waldo, coroner for the City of London, has issued, under the direction of the County Purposes Committee of the Corporation of the City of London, a set of instructions as to what to do in the case of fire, together with points for the prevention of fire.

The connexion between the office of coroner and the prevention of fires may seem somewhat remote, but under the City of London Fire Inquests Act of 1888, which is unique in its scope in Great Britain, it is the duty of the coroner for the City to conduct judicial inquiry into the cause and all the circumstances (including construction and means of escape from fire) of non-fatal as well as fatal fires. The City coroner has power to send persons on his inquisition for trial for arson or incendiarism. From 23 years' experience of fires gained in this way Dr. Waldo has drawn up his suggestions, which are printed in the form of fire cards, to be distributed among offices, workshops, and other buildings in the 26 wards of the City. Larger poster-notices are to be exhibited in public buildings and schools. Dr. Waldo says that the public generally are intensely ignorant about all matters connected with fires, and that the education of the rising generation is the best fire insurance against unnecessary loss of life and property. He finds, for instance, that few citizens (save police constables) know the whereabouts of the nearest street fire-alarm to their premises. Not uncommonly, again, on the breaking out of a fire, persons on using the 'phone merely say—Fire! and, without waiting to give their address, replace the receiver and await the arrival of the fire brigade, which, of course, never comes. Further, he emphasises the extreme importance of calling the brigade at once in all cases of fire. Copies of the fire cards and posters can be obtained from the town clerk, Guildhall, London, E.C.

A SELF-ACTING SYRINGE.

AT the thirty-sixth Congress of the German Society for Internal Medicine, held recently in Bad Kissengen, there was exhibited a new syringe for injection and aspiration invented by Felix Myer, of Aix-les-Bains. The syringe is made of glass, and is sold ready filled with an accurately measured quantity of the required drug, the needle being welded on to the body. After use the instrument can be thrown away. The motive power is supplied by a carefully regulated amount of sterilised compressed air which can be released by a simple movement. For aspiration purposes the same principle is employed, only in this case a sterile vacuum takes the place of the drug and the compressed air. This type can also be used for venepuncture. The advantage lies in obviating frequent and repeated sterilisation of the syringe and in each case a new and sharp needle is employed. A point about the syringe is that when making intravenous injections or in withdrawing blood from a vein a small capillary tube inside the syringe allows the operator to see whether the vein has been correctly pierced before the syringe is put into action.

---

[1] A detailed review of Mr. MacGregor's study of anophelines in Mauritius appeared in THE LANCET of June 14th, p. 1228.

Oliver-Sharpey Lectures.

Delivered before the Royal College of Physicians of London

BY A. V. HILL, Sc.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON.

LECTURE I.—THE RECOVERY PROCESS IN ISOLATED MUSCLE.

THE CONSISTENCY OF NATURE.

FORTUNATELY for physiology and medicine many human functions are sufficiently akin to those of animals to make it possible to apply the results obtained by studying one reciprocally to the other. Recent advances in medicine make it indeed unnecessary to emphasise this fact. Fortunately too many organs, especially in the lower animals, can be made to function apart from the body; we may, so to speak, isolate our variables and examine them one at a time. It is probable that a great field of research lies in the future before a study which is still quite young, that of tissue cultures. Fortunately, too, nature is consistent—though to believe that this is so requires on occasions a certain amount of scientific faith. It is a great reward to that faith when examples of this consistency appear, as indeed they do in the subject on which I am to have the privilege of speaking to you.

ACADEMIC PHYSIOLOGY.

The study of muscle and nerve was for long one of the chief activities of many of the finest intellects in physiology. I need mention only a few, the names of Burdon-Sanderson and Gotch, of Helmholtz, Fick, and Blix, of Keith Lucas, Gaskell, and Mines. The strongest motive—indeed, the only good motive—for investigating a "useless" and academic subject is the same as led Pasteur to study optical activity, or the physicists of the last century to study the conduction of electricity through gases—viz., an interest in the phenomena for their own sake. One knows now the practical importance of Pasteur's work, X rays and wireless telegraphy are a sufficient practical illustration of the value of physics. It would, indeed, be unnecessary here to advocate, to make an apology for, these academic studies, were what is said here not sometimes heard outside. The fact that you have done me the honour of inviting me to give these lectures is a sign that you, at any rate, do not regard the apparently useless as not to be encouraged. The best motive, because the most effective, in investigation and research, is simply the desire for knowledge, not merely the pursuit of power or money, or even the improvement of the amenities of human life. The desire to prevent suffering, noble in itself as it is, would never of itself have led to the discovery of X rays, nor will it lead to the elimination of diseases produced by filter-passing organisms or of the scourge of cancer. One's head, indeed, must be tempered by one's heart, but one's head is still the organ by which intelligent progress is made.

In physiology, however, the young people whom one has to teach are often so severely practical; they have escaped from the "useless" learning of school, they have "put away childish things," and if one wants to tell them about the refractory period of nerve or the recovery process in muscle, they say—sometimes openly to oneself, almost invariably to one another—"What is the use of that? What application can this have in the wards?" and they go off probably—small blame to *them*—to someone else, who will cram them better for their examinations so that they may get on the quicker with something useful.

An opposition, however, is not a bad thing, as Parliamentary Government shows. No dictatorship, least of all in science, is good, either for the dictator or for those to whom he dictates. It is an excellent thing for our students to be free to ask us, "What is the use of this, or that?" and to have us reply that it is no use—at any rate, at present—that we do not tell them things because they are useful, but because they are interesting. It is a great stimulus to us to have to find applications, in living man, of the facts discovered on portions of frog or cat; indeed, the greater part of the information which I hope to discuss with you in my second lecture was acquired directly under that kind of stimulus. One told one's students about lactic acid and the recovery process in isolated muscle; the presence in the laboratory at Manchester of my colleague, Dr. F. W. J. A. Lamb, with a special sub-department of human physiology, together with the ever-present, if unexpressed, desire of one's students to hear about man rather than about the frog, led one to see how application could be made. My colleagues, Lupton and Long, aided by the Medical Research Council, have made many of the applications which I hope to describe in my second lecture.

Mutual Dependence of the Theoretical and Practical.

To every action there is an equal and opposite reaction. Often, after the first step has been made on the academic side and applied on the practical side, the latter reacts on the former by suggesting further problems, by providing a new or a better technique. One can see it in physics; physical progress depends largely on instruments and technique. Technology requires, with a certain latent period, the new advance on the theoretical and academic side. To take a personal example, I have recently been privileged to collaborate with my friend Prof. Gasser, of St. Louis, in an extraordinarily interesting development of a very old subject, one that we, like many other people, had thought moribund, the mechanics of muscular contraction. This work arose directly from, and I think might never have arisen without, a series of experiments made three years ago on the relation between speed and efficiency in human muscular movement, a subject of practical, even of industrial, importance. Those experiments, in their turn, had arisen from a study of the thermodynamics and the absolute efficiency of muscular movement in the frog. To take another example. Experiments on the electric change in isolated tissues led to the study of the human electrocardiogram; the phenomena of fibrillation and flutter in man led to the further study of circus movement in the exposed mammalian heart and of the changes of refractory period associated therewith. This in its turn will lead to further knowledge of human cardiac disorders. To take a third example. The importance of human diabetes has long stressed the interest of pancreatic function in animals; that has led to the discovery of insulin, a subject not only of great practical importance, but of very considerable scientific interest in relation to metabolism, oxidation, and, ultimately, to the mechanism of muscle. We academic physiologists must not be ungrateful to our students and our practical medical friends—our Parliamentary opposition—if they stimulate us to widen our views and prove the practical application of our studies; for the needs and problems of those applications will, and must, react in the end to our good.

Let me now, after this attempt at an apology, turn to my thesis.

MUSCULAR FATIGUE.

The isolated muscle stimulated in air, or in Ringer's solution saturated with air, with more than a certain frequency, rapidly fatigues; stimulated with a lower frequency, it lasts a longer time; stimulated infrequently it may remain alive for several weeks. If maintained in Ringer's solution saturated with oxygen, it may be stimulated every ten seconds for several days; with very frequent stimulation it is completely exhausted in a few hundred twitches. Left without oxygen, it never recovers from this fatigue; in a few hours it goes into rigor and dies. Left in oxygen, however, it completely recovers, its contracture disappears, and it is ready to function again as well as ever. Moreover, in oxygen it will rapidly reach a steady state (Fig. 1) in which breakdown in activity is balanced exactly by restoration in recovery. This steady state in oxygen, which was first clearly pointed out by Fletcher, is of peculiar importance when we come to study prolonged human muscular activity.

LACTIC ACID.

Such observations on the isolated muscle led to a study of lactic acid—its accumulation in activity, its removal in recovery. Fletcher and Hopkins's experiments, published in 1907, are now the basis of all muscle physiology. In a muscle left at rest in oxygen the lactic acid concentration never increases and may decrease; in a muscle left in air, it increases slowly; more rapidly, however, in inert gases such as hydrogen or nitrogen. If a muscle be subjected to some harmful influence, such as mechanical injury, coal-gas, alcohol, or chloroform, its lactic acid content increases rapidly. This anaerobic production of lactic acid is increased by a rise of temperature, an effect which culminates in an almost explosive production of lactic acid during heat rigor, which occurs, in such an animal as the frog, at about 35·5° C. When a muscle is initially fatigued and then left in oxygen, its lactic acid concentration continually falls over a period of hours—that is, the recovery process—and the muscle becomes as capable as before of reacting to a stimulus. In such a case—regarded from the standpoint of the intact animal—the oxygen supply is grossly inadequate, owing to the slowness of its diffusion through the muscle substance from outside. The recovery process, in the presence of an adequate supply of oxygen, as in man after moderate exercise, or in the isolated muscle after a single twitch, is far more rapid. This abolition of lactic acid during the recovery process does not appear to diminish the total amount of it which can be obtained later from the same muscle by stimulation, by mechanical injury, or by heat rigor; either it is not oxidised but rather restored to some previous position in the chemical architecture of the muscle, or there is some limit to the lactic acid concentration set by its own presence there, for example, by the rise in hydrogen-ion concentration which it causes. We shall see later that both explanations are essentially true.

These experiments of Fletcher and Hopkins, which have been fully and widely confirmed since by Meyerhof and others, were obviously of fundamental importance in the study of muscle. They were the starting-point of the investigation which Prof. Langley proposed to me in 1909, as they were the basis of Meyerhof's recent work. They clearly opened up all kinds of problems—what happened to the lactic acid when it was removed in recovery? How long did the process take when the oxygen supply was adequate? Was the lactic acid the essential link in the chain of muscular contraction, or only a by-product to be got rid of as soon as possible? Many of these questions have since been answered, largely by the aid of experiments on the heat production of muscles under various circumstances.

HEAT PRODUCTION OF MUSCLES.

There is a special advantage in studying the heat production of muscles; this will be obvious to any who, in these mechanical days, like to regard the muscle as a machine. The first and most important factor in a machine is the amount of energy which it uses. A much more important advantage, however, in studying muscle is the fact that *heat* measurements can be made without injuring the tissue, continuously while the processes inside it are going on. To study the *chemical* changes in a muscle requires us to destroy it each time we make an observation. The sensitivity, moreover, of the thermo-electric method, applied to measurements of heat in muscle, is so great that it is possible to examine, during and after a single twitch, the processes which can be studied by chemical methods only after severe activity.

RIGOR MORTIS.

We have learnt a great deal in this connexion from the study of rigor mortis. When a frog's muscle is warmed to 35° C. or more it goes rapidly into rigor, the only chemical process known to accompany this condition being the production of lactic acid—as Fletcher and Hopkins showed—followed by the effect of the acid in producing stiffness or coagulation of the muscle substance. The heat liberated during rigor is one to two calories per gramme of muscle. Seeing that no chemical processes are known to accompany rigor except the lactic acid production, it was natural to attribute this liberation of heat to the unknown process by which the lactic acid also is liberated. This rigor heat is considerably reduced by previous injury, by prolonged anaerobic survival, or by stimulation. The same heat may be liberated in rigor produced by chloroform; it also is reduced by survival without oxygen and by fatigue. Its level is restored by oxygen after fatigue, and maintained at a high level during resting survival in the presence of oxygen. The heat liberated per gramme of lactic acid was estimated roughly in 1912 as being about 370 calories. Recent and much more accurate measurements by Meyerhof have confirmed this value. Peters, in 1913, found that the heat liberated during stimulation to complete fatigue is about 0·9 calories per gramme. The heat liberated in subsequent rigor is about 0·87 calories. Rigor in the unstimulated muscle gave about 1·7 calories. Stimulation of fresh muscles leads to the liberation of about 0·2 per cent. lactic acid; rigor to one of about 0·4 per cent.; stimulation followed by rigor also to about 0·4 per cent. Hence it is obvious that lactic acid and heat formation run parallel to one another, and that rigor and anaerobic activity involve the same chemical change—namely, the production of lactic acid from some precursor with the liberation of about 370 calories for every gramme of acid set free.

ORIGIN OF LACTIC ACID.

This determination of the heat production associated with the formation of 1 g. of lactic acid, either in rigor or in the anaerobic activity of muscle, enables us to decide with fair certainty what are the chemical reactions associated with contraction, and from what substance the lactic acid arises. Now, it is probable on other grounds that glycogen is the precursor of lactic acid. The heat of combustion of dissolved glycogen $(C_6H_{12}O_6)n$ has been determined by Slater as 3836 calories, that of lactic acid $(C_3H_6O_3)$ by Meyerhof as 3601 calories per gramme; the formation, therefore, of lactic acid from glycogen is accompanied by the liberation of 235 calories per gramme. Now, as we shall see shortly, this lactic acid never occurs as such to any appreciable degree inside a muscle; it is always there neutralised in the form of sodium or potassium lactate. There are grounds for believing that the neutralisation takes place at the expense of a sodium protein salt, the alkali protein substance of the muscle itself. According to Meyerhof the heat of this neutralisation is 135 calories, so that the total heat associated with the formation of lactic acid from glycogen and its subsequent neutralisation would be 370 calories. This is precisely the amount of heat set free when 1 g. of lactic acid is formed inside a muscle during activity or rigor. It is obvious, therefore, that in the initial process of contraction and relaxation—i.e., apart from recovery—no chemical change of any importance occurs except the formation of lactic acid at the expense of glycogen and its subsequent neutralisation. There may be small, and from the energy standpoint unimportant, side reactions, but it is a great simplification to know that the fundamental chemical process underlying a contraction is simply the formation of *lactic acid from glycogen.*

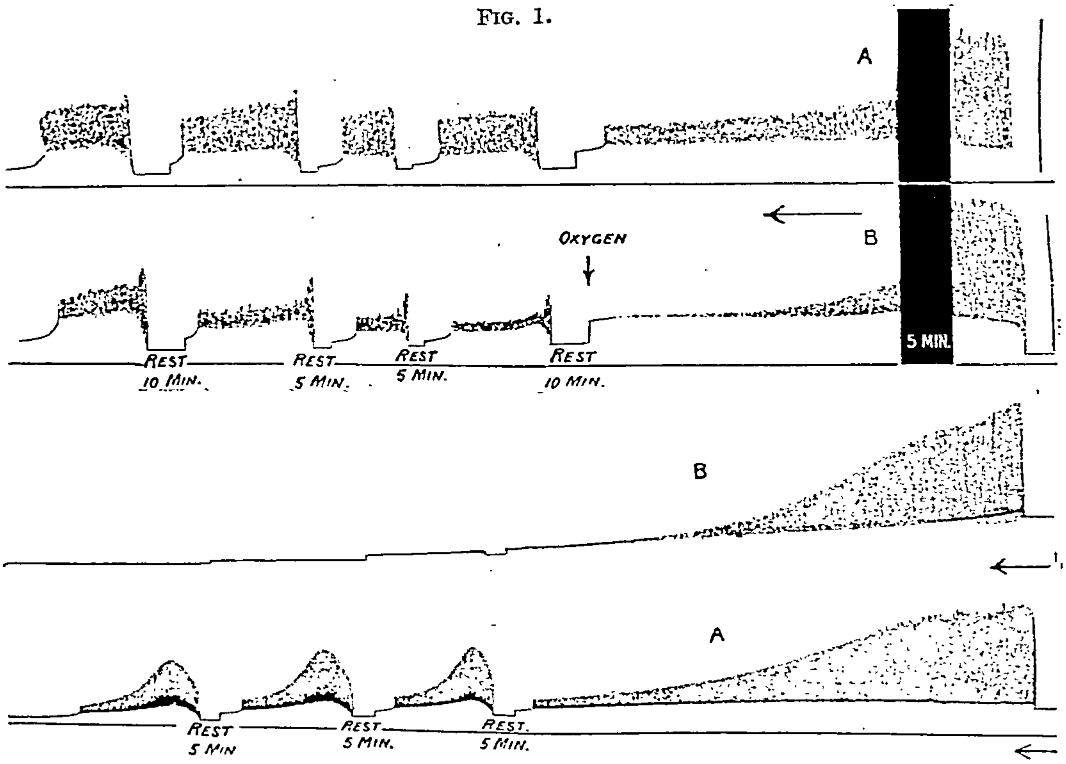
That glycogen is, indeed, the precursor of lactic acid in the muscle is shown by the direct determinations of Meyerhof, which have been confirmed in Hopkins's laboratory. During anaerobic activity, or survival, glycogen disappears from the muscle and lactic acid appears in exactly equivalent amount; CO_2 is driven out by the lactic acid from the bicarbonate present in the muscle; heat is liberated proportional to the lactic acid. No change, however, is observed in the fat, and the lactic acid maxima are, in exercise 0·25 to 0·4 per cent., in rigor 0·4 to

0·7 per cent. The reaction is apparently a self-inhibited one; it is stopped by the rise of hydrogen-ion concentration produced by the lactic acid and may be caused to go further by the presence around the muscle of alkali and phosphates. Presumably the complete failure to contract, produced by muscular fatigue, is due to the same cause.

BUFFERS IN MUSCLE.

The accommodation in the muscle of these enormous quantities of lactic acid requires some special consideration. It has been stated that during activity a muscle becomes acid; so it does, but only very slightly. Were the acid free inside it the hydrogen-ion concentration would rise thousands of times as the result of a few contractions. Ritchie in 1922 showed, by an electro-metric method, that no appreciable change in the hydrogen-ion concentration of a muscle occurs after several seconds tetanus; the acid, therefore, is neutralised. In blood we know that there are various alkaline buffers—bicarbonate, phosphate, and particularly the sodium or potassium salt of hæmoglobin. These react with an added acid, forming a neutral salt and the undissolved buffer acid. So it is in muscle. The total amount, however, of bicarbonate and phosphate is insufficient to neutralise all the acid formed in exercise, and it has been shown by Meyerhof that the main part of the neutralisation occurs as the result of combination of the acid with the sodium protein salt of the muscle tissue itself. The amount and efficiency of this buffer constituent of the muscle are the chief factors enabling the muscle to stand high concentrations of acid—that is, to tolerate a high degree of activity.

FIG. 1.



The upper two tracings show fatigue of pair of gastrocnemii, (A) in oxygen, (B) initially in nitrogen 19° C. Max. break shocks every second. Note "steady state." The lower two show fatigue of pair of sartorii, (A) in oxygen, (F) in nitrogen. (Fletcher, 1902.)

MYOTHERMIC EXPERIMENTS.

I will pass on now to describe the experiments made by means of the thermo-electric method on the isolated muscle, which have enabled us to describe the time course of the events which happen during and after muscular activity. The thermo-electric method is a highly sensitive one; it is possible—if one desires—to obtain deflections of more than a kilometre for one degree centigrade! Such a sensitivity indeed is not wanted, since the rise of temperature in a muscle twitch is of the order of 3/1000th of a degree; it is necessary merely to read to the nearest 100,000th of a degree to obtain all the sensitivity required for such observations. It is essential to keep the muscle in its chamber far removed from any external temperature disturbances; this is done by sinking it under water maintained at a constant temperature in a large double-walled vacuum flask. Connected to a sensitive galvanometer the thermopile registers its changes of temperature on a revolving drum carrying photographic paper. When the muscle is stimulated its temperature rises and the galvanometer deflects, the moment of stimulus being recorded on the record. The deflection reaches a maximum comparatively slowly, owing to lag in conduction of heat into the thermopile and inertia of the galvanometer system. It then moves slowly back towards its original zero, owing to gradual equalisation of temperature along the thermopile and loss of heat by conduction to outside. The curves by themselves do not tell us much about the time course, or the absolute magnitude, of the liberation of heat; it is necessary to make a "control" experiment. A known amount of electrical energy, carefully measured, is liberated inside the same muscle after it is dead, in the same position on the thermopile, and the resulting rise of temperature is registered. The comparison of the maximum in the control heating, with the maximum when the muscle produces its rise of temperature by its own physiological activity, gives us in absolute units the heat production in the latter case. The comparison of the forms of the curves enables us, by a somewhat laborious numerical technique, to analyse the production of heat in the live muscle, as a function of the time. I say laborious: may I take this opportunity of emphasising how the results which I am just describing are mainly due to the skill and patience of my colleague, W. Hartree. Without him it would never have first clearly pointed out by Fletcher, is of peculiar importance when we come to study prolonged human muscular activity.

LACTIC ACID.

Such observations on the isolated muscle led to a study of lactic acid—its accumulation in activity, its removal in recovery. Fletcher and Hopkins's experiments, published in 1907, are now the basis of all muscle physiology. In a muscle left at rest in oxygen the lactic acid concentration never increases and may decrease; in a muscle left in air, it increases slowly; more rapidly, however, *in inert gases such as* hydrogen or nitrogen. If a muscle be subjected to some harmful influence, such as mechanical injury, coal-gas, alcohol, or chloroform, its lactic acid content increases rapidly. This anaerobic production of lactic acid is increased by a rise of temperature, an effect which culminates in an almost explosive production of lactic acid during heat rigor, which occurs, in such an animal as the frog, at about 35·5° C. When a muscle is initially fatigued and then left in oxygen, its lactic acid concentration continually falls over a period of hours—that is, the recovery process—and the muscle becomes as capable as before of reacting to a stimulus. In such a case—regarded from the standpoint of the intact animal—the oxygen supply is grossly inadequate, owing to the slowness of its diffusion through the muscle substance from outside. The recovery process, in the presence of an adequate supply of oxygen, as in man after moderate exercise, or in the isolated muscle after a single twitch, is far more rapid. This abolition of lactic acid during the recovery process does not appear to diminish the total amount of it which can be obtained later from the same muscle by stimulation, by mechanical injury, or by heat rigor; either it is not oxidised but rather restored to some previous position in the chemical architecture of the muscle, or there is some limit to the lactic acid concentration set by its own presence there, for example, by the rise *in hydrogen-ion concentration* which it causes. We shall see later that both explanations are essentially true.

These experiments of Fletcher and Hopkins, which have been fully and widely confirmed since by Meyerhof and others, were obviously of fundamental importance in the study of muscle. They were the starting-point of the investigation which Prof. Langley proposed to me in 1909, as they were the basis of Meyerhof's recent work. They clearly opened up all kinds of problems—what happened to the lactic acid when it was removed in recovery? How long did the process take when the oxygen supply was adequate? Was the lactic acid the essential link in the chain of muscular contraction, or only a by-product to be got rid of as soon as possible? Many of these questions have since been answered, largely by the aid of experiments on the heat production of muscles under various circumstances.

HEAT PRODUCTION OF MUSCLES.

There is a special advantage in studying the heat production of muscles; this will be obvious to any who, in these mechanical days, like to regard the muscle as a machine. The first and most important factor in a machine is the amount of energy which it uses. A much more important advantage, however, in studying muscle is the fact that *heat* measurements can be made without injuring the tissue, continuously while the processes inside it are going on. To study the *chemical* changes in a muscle requires us to destroy it each time we make an observation. The sensitivity, moreover, of the thermo-electric method, applied to measurements of heat in muscle, is so great that it is possible to examine, during and after a single twitch, the processes which can be studied by chemical methods only after severe activity.

RIGOR MORTIS.

We have learnt a great deal in this connexion from the study of rigor mortis. When a frog's muscle is warmed to 35° C. or more it goes rapidly into rigor, the only chemical process known to accompany this condition being the production of lactic acid—as Fletcher and Hopkins showed—followed by the effect of the acid in producing stiffness or coagulation of the muscle substance. The heat liberated during rigor is one to two calories per gramme of muscle. Seeing that no chemical processes are known to accompany rigor except the lactic acid production, it was natural to attribute this liberation of heat to the unknown process by which the lactic acid also is liberated. This rigor heat is considerably reduced by previous injury, by prolonged anaerobic survival, or by stimulation. The same heat may be liberated in rigor produced by chloroform; it also is reduced by survival without oxygen and by fatigue. Its level is restored by oxygen after fatigue, and maintained at a high level during resting survival in the presence of oxygen. The heat liberated per gramme of lactic acid was estimated roughly in 1912 as being about 370 calories. Recent and much more accurate measurements by Meyerhof have confirmed this value. Peters, in 1913, found that the heat liberated during stimulation to complete fatigue is about 0·9 calories per gramme. The heat liberated in subsequent rigor is about 0·87 calories. Rigor in the unstimulated muscle gave about 1·7 calories. Stimulation of fresh muscles leads to the liberation of about 0·2 per cent. lactic acid; rigor to one of about 0·4 per cent.; stimulation followed by rigor also to about 0·4 per cent. *Hence it is obvious that lactic* acid and heat formation run parallel to one another, and that rigor and anaerobic activity involve the same chemical change—namely, the production of lactic acid from some precursor with the liberation of about 370 calories for every gramme of acid set free.

ORIGIN OF LACTIC ACID.

This determination of the heat production associated with the formation of 1 g. of lactic acid, either in rigor or in the anaerobic activity of muscle, enables us to decide with fair certainty what are the chemical reactions associated with contraction, and from what substance the lactic acid arises. Now, it is probable on other grounds that glycogen is the precursor of lactic acid. The heat of combustion of dissolved glycogen ($(C_6H_{12}O_6)n$ has been determined by Slater as 3836 calories, *that of lactic acid* ($C_3H_6O_3$) by Meyerhof as 3601 calories per gramme; the formation, therefore, of lactic acid from glycogen is accompanied by the liberation of 235 calories per gramme. Now, as we shall see shortly, this lactic acid never occurs as such to any appreciable degree inside a muscle; it is always there neutralised in the form of sodium or potassium lactate. There are grounds for believing that the neutralisation takes place at the expense of a sodium protein salt, the alkali protein substance of the muscle itself. According *to Meyerhof the heat* of this neutralisation is 135 calories, so that the total heat associated with the formation *of lactic acid from* glycogen and its subsequent neutralisation would be 370 calories. This is precisely the amount of heat set free when 1 g. of lactic acid is formed inside a muscle during activity or rigor. It is obvious, therefore, that in the initial process of contraction and relaxation—i.e., apart from recovery—no chemical change of any importance occurs except the formation of lactic acid at the expense of glycogen and its subsequent neutralisation. There may be small, and from the energy standpoint unimportant, side reactions, but *it is a* great simplification to know that the fundamental chemical process underlying a contraction is *simply the formation* of lactic acid from glycogen.

That glycogen is, indeed, the precursor of lactic acid in the muscle is shown by the direct determinations of Meyerhof, which have been confirmed in Hopkins's laboratory. *During* anaerobic activity, or survival, glycogen disappears from the muscle and lactic acid appears in *exactly* equivalent amount; CO_2 is driven out by the lactic acid from the bicarbonate present in the muscle; heat is liberated proportional to the lactic acid. No change, however, is observed in the fat, and the lactic acid maxima are, in exercise 0·25 to 0·4 per cent., in rigor 0·4 to

THE ADRENALIN TREATMENT OF STOKES-ADAMS ATTACKS.

BY JOHN PARKINSON, M.D., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL AND PHYSICIAN-IN-CHARGE OF THE CARDIOGRAPHIC DEPARTMENT; PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR DISEASES OF THE HEART;

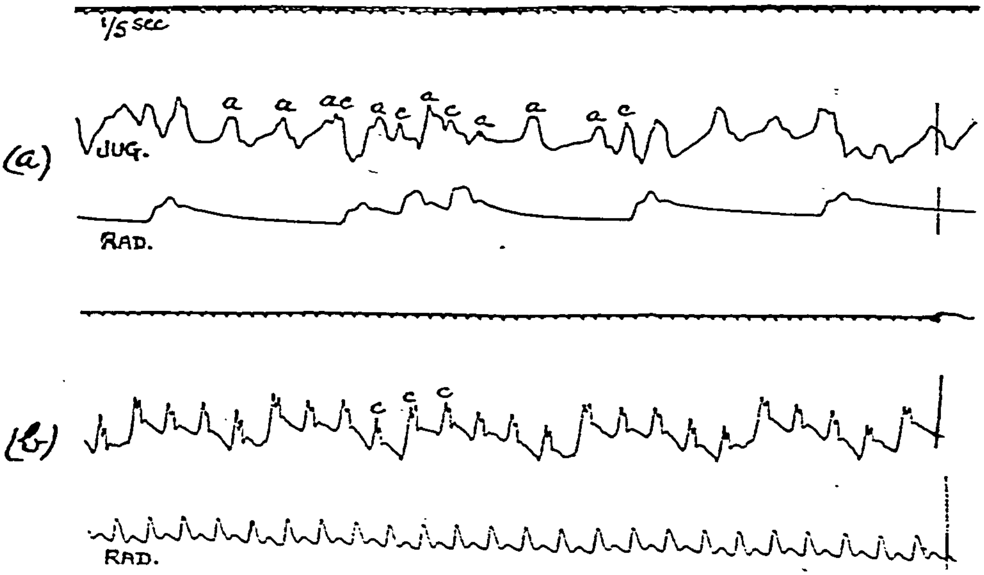
AND

C. W. CURTIS BAIN, M.B., B.CH. OXF., M.R.C.P. LOND.,
LATE RESIDENT MEDICAL OFFICER, NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

THE possibility of using adrenalin in the treatment of Stokes-Adams attacks has been raised by pharmacological evidence of its power to increase the auricular and ventricular rate independently and even to reduce auricular-ventricular block. Phear and Parkinson[1] have discussed this evidence in reporting its successful clinical application in a patient with complete heart-block who had been undergoing attacks almost incessantly for a week. These were abolished within 15 minutes by a subcutaneous injection of adrenalin, 5 minims (0·3 c.cm.) of a 1:1000 solution. Atropine, previously tried, had failed to influence the attacks. In the following year Feil[2] reported his observations on a man of 50 with complete heart-block and frequent syncopal attacks. After atropine had failed, a subcutaneous injection of adrenalin, 10 minims (0·6 c.cm.) of a 1:1000 solution, immediately stopped the attacks. When they recurred 12 hours later, and again 24 hours later, they were on each occasion stopped by a similar injection. The effect produced in both these cases seems to have been simply to abolish the periods of ventricular standstill, for at the time no change in ventricular rate occurred.

We have recently had an opportunity of repeating this method in the case of a man admitted to the National Hospital for Diseases of the Heart under the care of Dr. Strickland Goodall, who very kindly placed him at our disposal for this purpose.

FIG. 1.



Polygrams: (a) Before adrenalin; severe heart-block with a ventricular rate of 28, except for occasional A-V :: 1:1 beats. (b) Twelve minutes after a subcutaneous injection of adrenalin (♏x.); rate 110.

A man of 44, a cook, was admitted to hospital at 7 P.M. on Feb. 22nd, 1924, with a history of good health until the previous day, when at 9 A.M. and again at 11 A.M. he noticed for a few seconds a mist in front of his eyes. At 1 P.M., while serving dinners, he lost consciousness and fell. He was picked up having recovered consciousness, and went on working. At 2 P.M. he had a similar attack in which he bruised his head, and at 2.10 P.M. he had a third. He went home to bed and there had three more attacks. He passed a good night but woke with throbbing pains in the head followed by several attacks. From that time there were no more till after admission.

There was no history of acute rheumatism, chorea, syphilis, nor of any other infection; and the Wassermann reaction was negative. He was of good physique, in no distress, but rather looked well. There was no cyanosis, no pallor, no dyspnœa, and he could lie flat in bed. The apex-beat was in the fifth space in the nipple line. The sounds were normal, though there were intermissions about to be described. The arteries were palpable and slightly tortuous. The systolic blood pressure was 140 mm. Hg and the diastolic 75. X ray inspection revealed slight enlargement of the heart to the left and the apex-beat in the nipple line; this was confirmed by orthodiagram. Polygrams showed a normal A-V sequence at the rate of 73 with frequent extrasystoles and from time to time ventricular pauses lasting up to six seconds. These were perceived by the patient but did not inconvenience him.

Course.

During the next three weeks the patient passed through three phases in respect of cardiac conduction. The first was that of a rapidly increasing heart-block which became complete after 30 hours. During the next 12 days the dissociation remained complete (second phase). The third phase, lasting eight days, was ushered in by a striking increase in the number of syncopal attacks, and characterised by a gradual recession of the block ending in the spontaneous resumption of normal rhythm.

First Phase.—During the night he had several syncopal attacks in which he grunted, flushed, turned his head sharply to one side, and remained unconscious for a moment. Immediately after one of them a continuous polygram showed an auricular rate of 100 per minute and a ventricular rate of 28 per minute, except for occasional runs of two to five normal beats (1 : 1 rhythm). (Fig. 1.) Five minutes after a subcutaneous injection of 10 minims (0·6 c.cm.) of adrenalin (1 : 1000 solution) the runs of normal beats had become longer and more frequent, and 12 minutes after the injections the whole record was regular at the rate of 110 (Fig. 1). Owing, perhaps, to the more violent carotid pulsations induced by adrenalin, "a" waves cannot be identified on this tracing; but an electrocardiogram taken later under similar circumstances showed been possible to do more than a fraction of what I am describing in these lectures. This work is really his and not mine, which gives me the better excuse and makes it the greater pleasure to be able to present it to you.

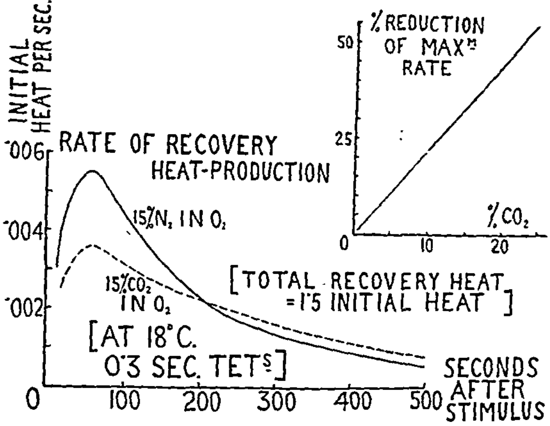
THE RECOVERY HEAT PRODUCTION.

In the analysis of the heat production of the live muscle the first result we obtain is that a large amount of heat is liberated directly the contraction begins; then there is a pause, and again there is a liberation of heat during relaxation. It is natural to associate the first production of heat with the formation of lactic acid from glycogen, the second production of heat with the neutralisation of the lactic acid. It is soon found, however, that the heat production is not finished when the muscle has relaxed; the deflection of the galvanometer when the muscle is in oxygen returns only slowly to zero, far more slowly than in a dead muscle warmed suddenly at the beginning. This can be due in the live muscle only to a continual formation of heat for long periods after the contraction is over, this heat maintaining the temperature of the thermopile and the deflection of the galvanometer. This recovery heat production, as it is called, goes on for 10 to 20 minutes at room temperature (Fig. 2); at 0° it may be apparent nearly an hour after the stimulus. It is clearly concerned with the oxidative removal of lactic acid, which was found by Fletcher and Hopkins to occur in oxygen after activity. It is not affected, however, by diffusion, since the muscle contains, dissolved in its own substance, more than enough oxygen to account for the small amount of heat actually liberated in recovery from a single contraction. We do not know in detail what the events are which occur during this restoration process. The curve, however, of the recovery heat production represents the thermodynamic outline into which must be fitted the picture of the recovery process as a whole, which will be painted in the future by the biochemists.

FIG. 2.



Factors Affecting the Speed of Recovery.

It is noticeable that the rate of the recovery process increases, not only absolutely but relatively, when the extent of the initial breakdown is greater. Recovery appears to be determined by some kind of bi-molecular reaction. The presence of lactic acid in the muscle is a sensitive "governor" of oxidation; the speed of the latter increases as the square of the concentration of the former. This may not seem in itself of great practical account; we shall see, however, in the next lecture how large a determining factor it is in the degree of fatigue resulting from a given amount of muscular exercise.

The recovery heat production is affected by a variety of factors. A rise in hydrogen-ion concentration (see Fig. 2) diminishes its rate, while leaving its total magnitude unaltered. A large decrease in the rate of recovery may be produced by a comparatively small rise in the hydrogen-ion concentration inside the muscle fibre. This is analogous to the effect produced by hydrogen-ion concentration on the rate of autoxidation of cysteïn or glutathione, or, according to a private communication from Prof. Meyerhof, of the oxidation of fructose in the presence of phosphates. The rate of recovery is increased by a rise of temperature; it is diminished by soaking the muscle for some time in Ringer's solution—possibly the soaking of the muscle removes some oxidising catalyst analogous to Hopkins's glutathione.

Chemical Events in Recovery.

I said that the curves of the recovery heat production represent the thermodynamic outlines of the future chemical picture. Fortunately, some details of that chemical picture are already known and fit well into the outline. In a muscle kept in oxygen no lactic acid ever appears; lactic acid already formed disappears; oxygen is used and carbon dioxide is produced in excess of the resting values. The excess CO_2 is equal to the excess oxygen—i.e., the R.Q. of recovery is unity. The restoration process, therefore, in the isolated muscle (probably not in the intact animal) involves the oxidation of something with the general formula of carbohydrate. There is no sign of change in the fat inside the muscle; heat, as we have seen, is liberated, and—most important of all—*glycogen has been shown by Meyerhof to be re-formed.*

From the oxygen used and the CO_2 produced we may calculate the carbohydrate oxidised. The amount of glycogen re-formed, plus this amount of carbohydrate oxidised, is shown experimentally to be exactly equal to the amount of lactic acid which has disappeared. It would seem, therefore, that the lactic acid is mainly or entirely re-formed into glycogen during recovery, but that a certain amount of energy (obtained from the oxidation, either of a part of the lactic acid, or of carbohydrate) is necessary in order to force the reaction backwards. The matter is best discussed from the purely energetic standpoint.

In the anaerobic process of activity—the process producing fatigue—glycogen becomes sodium lactate with the evolution of 370 calories per gramme of lactic acid. In the recovery process the reaction is reversed, sodium lactate becomes glycogen, and 370 calories therefore of energy must be absorbed. This in itself would lead to a cooling of the muscle. Actually Hartree and I have found that in the process of "recovery" there is an extra oxidative heat production almost exactly equal to the total anaerobic heat production of the previous process of "fatigue." The total recovery heat, therefore, is 370 calories, so that the total energy liberated in recovery is 740 calories. The heat of combustion, however, of dissolved glycogen is 3836 calories. Hence, in the complete cycle by which 1 g. of glycogen becomes 1 g. of lactic acid and then is restored from the acid, the fraction $740/3836 = 0{\cdot}193$ g. of glycogen must be oxidised to provide the necessary energy. The initial process of contraction is forced backwards by the energy liberated in this oxidation. This reversal is the recovery process.

"Efficiency" of Recovery.

The ratio of the lactic acid removed during recovery to the lactic acid, or carbohydrate, oxidised to provide the necessary energy for its removal, may be called the "efficiency of recovery"; it appears to be about 5·2 : 1—five to six molecules are removed for every one oxidised. Direct chemical measurements by Meyerhof of the glycogen and lactic acid showed that the efficiency of recovery is about 3 or 4 : 1. In these experiments, however, owing to the slowness of oxygen-supply by diffusion, the process was a very prolonged one and involved considerable oxygen-want; the efficiency of recovery may well have been less. It has proved possible on man to make similar observations of the efficiency of recovery; they have led to values similar to that obtained on isolated muscle. These values are perhaps the best reward we have had for the faith that nature is consistent. I will discuss them more fully in my next lecture.

THE ADRENALIN TREATMENT OF STOKES-ADAMS ATTACKS.

By JOHN PARKINSON, M.D., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL AND PHYSICIAN-IN-CHARGE OF THE CARDIOGRAPHIC DEPARTMENT; PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR DISEASES OF THE HEART;

AND

C. W. CURTIS BAIN, M.B., B.Ch. Oxf., M.R.C.P. Lond.,
LATE RESIDENT MEDICAL OFFICER, NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

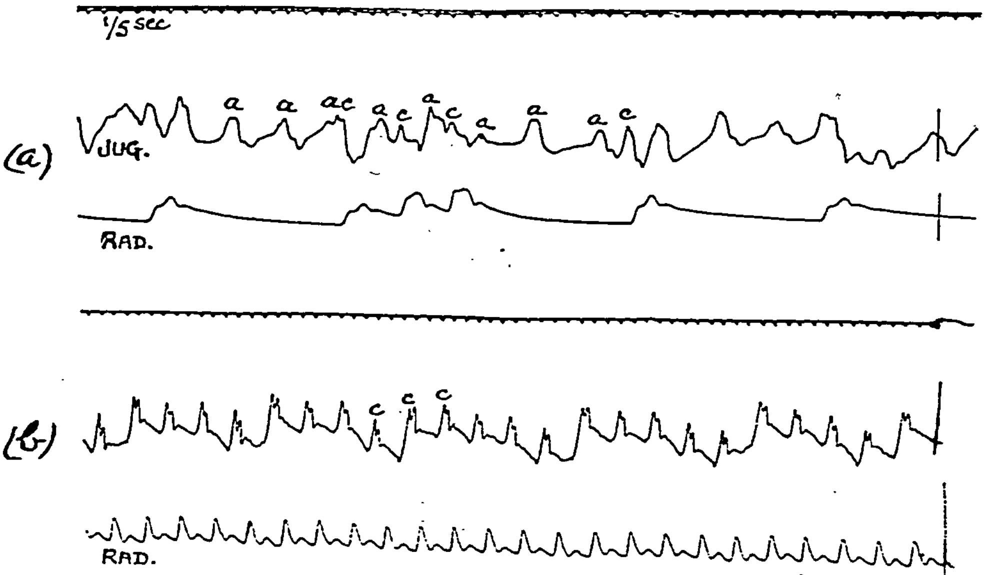
THE possibility of using adrenalin in the treatment of Stokes-Adams attacks has been raised by pharmacological evidence of its power to increase the auricular and ventricular rate independently and even to reduce auricular-ventricular block. Phear and Parkinson[1] have discussed this evidence in reporting its successful clinical application in a patient with complete heart-block who had been undergoing attacks almost incessantly for a week. These were abolished within 15 minutes by a subcutaneous injection of adrenalin, 5 minims (0·3 c.cm.) of a 1 : 1000 solution. Atropine, previously tried, had failed to influence the attacks. In the following year Feil[2] reported his observations on a man of 50 with complete heart-block and frequent syncopal attacks. After atropine had failed, a subcutaneous injection of adrenalin, 10 minims (0·6 c.cm.) of a 1 : 1000 solution, immediately stopped the attacks. When they recurred 12 hours later, and again 24 hours later, they were on each occasion stopped by a similar injection. The effect produced in both these cases seems to have been simply to abolish the periods of ventricular standstill, for at the time no change in ventricular rate occurred.

We have recently had an opportunity of repeating this method in the case of a man admitted to the National Hospital for Diseases of the Heart under the care of Dr. Strickland Goodall, who very kindly placed him at our disposal for this purpose.

A man of 44, a cook, was admitted to hospital at 7 P.M. on Feb. 22nd, 1924, with a history of good health until the previous day, when at 9 A.M. and again at 11 A.M. he noticed for a few seconds a mist in front of his eyes. At 1 P.M., while serving dinners, he lost consciousness and fell. He was picked up having recovered consciousness, and went on working. At 2 P.M. he had a similar attack in which he bruised his head, and at 2.10 P.M. he had a third. He went home to bed and there had three more attacks. He passed a good night but woke with throbbing pains in the head followed by several attacks. From that time there were no more till after admission.

There was no history of acute rheumatism, chorea, syphilis, nor of any other infection; and the Wassermann reaction was negative. He was of good physique, in no distress, but rather looked well. There was no cyanosis, no pallor, no dyspnœa, and he could lie flat in bed. The apex-beat was in the fifth space in the nipple line. The sounds were normal, though there were intermissions about to be described. The arteries were palpable and slightly tortuous. The systolic blood pressure was 140 mm. Hg and the diastolic 75. X ray inspection revealed slight enlargement of the heart to the left and the apex-beat in the nipple line; this was confirmed by orthodiagram. Polygrams showed a normal A-V sequence at the rate of 73 with frequent extra-systoles and from time to time ventricular pauses lasting up to six seconds. These were perceived by the patient but did not inconvenience him.

Fig. 1.



Polygrams: (a) Before adrenalin; severe heart-block with a ventricular rate of 28, except for occasional A-V :: 1 : 1 beats. (b) Twelve minutes after a subcutaneous injection of adrenalin (♏x.); rate 110.

Course.

During the next three weeks the patient passed through three phases in respect of cardiac conduction. The first was that of a rapidly increasing heart-block which became complete after 30 hours. During the next 12 days the dissociation remained complete (second phase). The third phase, lasting eight days, was ushered in by a striking increase in the number of syncopal attacks, and characterised by a gradual recession of the block ending in the spontaneous resumption of normal rhythm.

First Phase.—During the night he had several syncopal attacks in which he grunted, flushed, turned his head sharply to one side, and remained unconscious for a moment. Immediately after one of them a continuous polygram showed an auricular rate of 100 per minute and a ventricular rate of 28 per minute, except for occasional runs of two to five normal beats (1 : 1 rhythm). (Fig. 1.) Five minutes after a subcutaneous injection of 10 minims (0·6 c.cm.) of adrenalin (1 : 1000 solution) the runs of normal beats had become longer and more frequent, and 12 minutes after the injections the whole record was regular at the rate of 110 (Fig. 1). Owing, perhaps, to the more violent carotid pulsations induced by adrenalin, "a" waves cannot be identified on this tracing; but an electrocardiogram taken later under similar circumstances showed the presence of 1:1 A-V sequence (Fig. 3). Twenty-five minutes after the injection the rate had risen to 120 a minute, which proved to be the maximum. Three hours later the pulse was 75 and regular; but in another hour it had returned to the slow and irregular condition present before the injection, and a syncopal attack occurred. Next morning he had several short attacks, the period of ventricular standstill in one recorded instance measuring 17 seconds. Between the attacks the ventricular rate was 15 a minute, and the same short runs of normal rhythm (or rather 1:1 rhythm) were still seen. Adrenalin ♏x. was again given with the same result. A continuous polygram showed that within five minutes the ventricular rate had doubled; within 15 minutes the rate was 108 and the rhythm appeared to be normal; in 25 minutes the maximum of 118 was reached. Four hours later the rate had dropped to 32, and polygrams and electrocardiograms showed that complete block was present. It will be noted that after both injections the attacks completely disappeared for some hours.

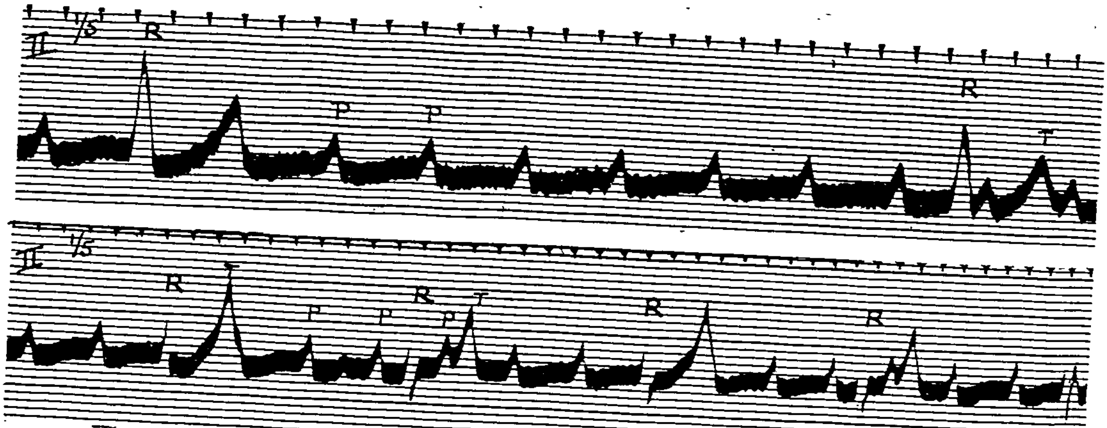
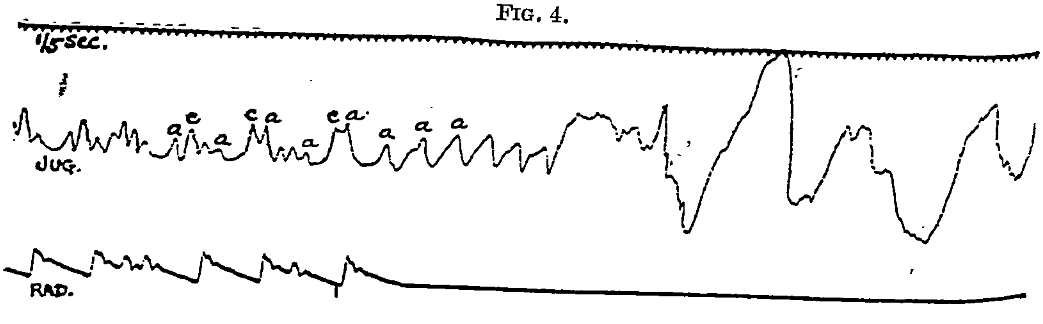
FIG. 2.



Electrocardiograms: (*a*) Before adrenalin; complete heart-block, P = auricular systole, R–T = ventricular systole; auricular rate 110, ventricular rate 12 a minute. (*b*) Ten minutes after a subcutaneous injection of adrenalin, ♏x. (0·6 c.cm.); complete heart-block; auricle 112, ventricle 33.

Second Phase.—During the next 12 days dissociation remained complete, though the ventricular rate varied within wide limits, the lowest recorded being 12 per minute (Fig. 2) and the highest 60. Syncopal attacks occurred irregularly, the patient enjoying complete freedom for one period of four days. No relationship could be traced between the changes in ventricular rate during complete block and the liability to syncopal attacks. Adrenalin was given on five occasions. It invariably abolished the attacks for some hours, but it never caused any reduction in the block when this was complete. The ventricular rate was increased to about 60 a minute, but never higher, while that of the auricle rose to 115. Thus a slow initial ventricular rate was considerably accelerated, while on one occasion when the rate was 60 before the drug was given, it was unaffected. The patient by this time had come to regard adrenalin as a specific for his attacks and begged for its regular administration to anticipate and prevent recurrence. It was thought better, however, to reserve it for occasions when the attacks were frequent.

FIG. 4.



Continued on opposite page.

Polygram showing the whole of a Stokes-Adams attack. *a* = auricular wave; *c* = carotid wave. After a short period of partial heart-block there is ventricular standstill for 18 seconds. Convulsive movements are indicated towards the end of the record, following stertorous breathing.

Third Phase.—Fourteen days after admission there was a sudden increase in the frequency of the attacks so that 100 were charted in a single night. The attacks were all of the same type but of variable duration. The patient became pale and the pulse stopped; he then lost consciousness and the breathing became stertorous; then in the longer attacks he was convulsed for a few moments (see Fig. 4). It will be noted that before and after the attack there is present a varying but always incomplete block with some A-V 1:1 beats. Before adrenalin was given on this occasion attacks had been recurring almost every minute for an hour. A continuous polygram showed an attack at the moment of injection, another one minute after, and then no more. The rate rose to 120 in 20 minutes, apparently with 1:1 rhythm as in phase 1. After two hours' freedom the attacks recommenced and 80 were charted during the next 12 hours. Adrenalin was then repeated and he slept undisturbed for six hours. Again the attacks recurred, and this time adrenalin was given promptly, preventing further attacks as expected. During the rapid rate which in this phase always followed the injection, an electrocardiogram was taken (Fig 3). It will be seen that normal A-V sequence is present, with a slightly prolonged P-R interval.

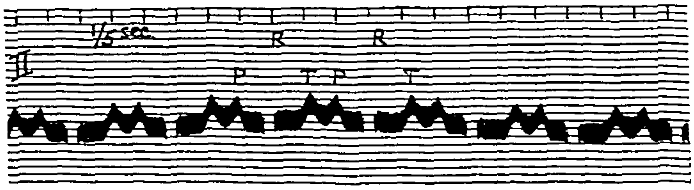
Two days later the attacks ceased altogether, and in three more days it was found that the heart had spontaneously reverted to normal rhythm. During the next five weeks he remained free from attacks and felt well, and electrocardiograms now always showed a normal rhythm. He remains well six weeks after discharge from hospital.

Discussion.

In their review of the literature, Phear and Parkinson came to the conclusion that there was sufficient evidence to show that partial heart-block may be reduced and even complete block abolished by the injection of adrenalin, while an increase in ventricular rate is usually obtainable. In their patient, as in Feil's, after the failure of atropine, adrenalin stopped the attacks; but the complete block present in both cases was unaffected and the rate was not increased at the time.

In the case here described, there appears to have been an acute lesion of the myocardium involving the auriculo-ventricular bundle, with a rapid onset of heart-block, and a period of complete dissociation followed by a more gradual recovery of conduction. Stokes-Adams attacks occurred in all three phases, but much the greater number took place during recovery of conduction. Opportunity was therefore afforded for studying the action of adrenalin both when the block was partial and when it was complete. On the 12 occasions on which it was used, with one doubtful exception, it abolished the attacks within three minutes; and freedom from attacks was maintained from 2 to 48 hours from the time of injection. On four recorded occasions when partial block was present, the auricular and ventricular rates both increased to 120 and normal auriculo-ventricular sequence was restored. When complete block was present and the ventricular rate was slow, this was increased to about 60, but the block remained complete. On one occasion, when the ventricular rate was already 60 before the injection, no increase in rate took place.

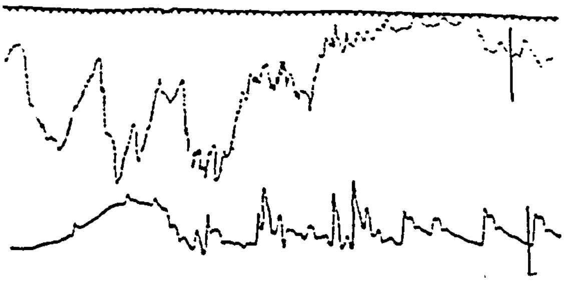
FIG. 3.



Electrocardiogram taken during the rapid heart action following adrenalin. P = auricular systole; R–T = ventricular systole. The P–R interval is slightly over one-fifth sec.; 1 : 1 rhythm is shown, at a rate of 100 a minute.

It must not be expected that adrenalin will succeed in every case showing Stokes-Adams attacks. We have seen two cases where the clinical effect of adrenalin was disappointing. 1. In a man of 72 with complete heart-block convulsive attacks were occurring at least every hour, two being observed in the 20 minutes preceding the injection of adrenalin ♏v. (0·3 c.cm.) On this occasion no more occurred for two hours, yet on the following day more severe attacks were uninfluenced by ♏x. (0·6 c.cm.) and the patient died in an attack, though ♏xv. (0·9 c.cm.) had been injected subcutaneously ten minutes before. 2. In a man of 70 with complete heart-block and syncopal attacks recurring several times daily, adrenalin ♏v. failed to affect either the auricular or ventricular rates (A-V : : 90 : 25) and an attack occurred 35 minutes after the injection.

FIG. 4—(*Continued.*)



The usual treatment of Stokes-Adams attacks in respect of drugs is the subcutaneous injection of atropine. This treatment is largely based upon the fact that where partial heart-block is present atropine by its action on the vagus may facilitate conduction and, in so far, may increase the ventricular rate. Where the heart-block is complete, it is not capable of increasing the rate of the ventricle. Whatever the block, it is only where the attacks depend upon strong vagal influence—a rare event—that atropine might be expected to succeed. Clinical experience confirms this and shows that it is most uncommon for atropine to control attacks.

On pharmacological grounds adrenalin might be expected to have a wider application than atropine in the treatment of Stokes-Adams attacks. It can facilitate conduction when partial block is present. What is more important is that it can directly increase the rate of a dissociated ventricle. Further, it has now been shown clinically that, even if the block is uninfluenced and the ventricular rate is not increased, adrenalin can abolish the recurrent standstill of the ventricle which under these conditions determines the syncope.

We are of opinion that the subcutaneous injection of adrenalin, 5–10 minims (0·3–0·6 c.cm.) of the 1 : 1000 solution, is the most promising method of treating Stokes-Adams attacks, and should therefore be tried in every case.

MENTAL DEFECT AND MENTAL DEGENERACY IN A RURAL AREA.

BY G. K. BOWES, M.D. OXF., M.R.C.P. LOND., D.P.H.,
ASSISTANT COUNTY MEDICAL OFFICER, WILTSHIRE.

THIS paper is based upon information obtained in the ascertainment of mental defectives among school children in a rural area during a period of two and a half years, beginning in January, 1921. It is laid down in the Mental Deficiency Act of 1913 that it is the duty of a local education authority to ascertain the number of mentally defective children in the school population; but where, as in most rural districts, no special schools are available for mentally defective children, this Act has for the most part been a dead letter. Hence, mainly, the very varied nature of the figures quoted as to the number of mental defectives in rural areas. It is hoped that the present paper, based upon information as complete as possible under existing conditions, will serve as a contribution to knowledge of the problem of mental defect as it exists in rural areas.

Method of Ascertainment.

As the routine medical inspection of the children in the area under investigation is done by me, I have examined the greater proportion at some time or another. Opportunities occur during a routine inspection of noting children who require special examination for mental defect. Such points as an obviously abnormal manner and appearance, or an unduly low school standard for the age, may serve as indications for special examination. But it must not be supposed that more than a minority of mental defectives can be picked out by such indications. The greatest reliance has to be placed on the teacher in bringing forward suspected cases, or those who are exceptionally backward. But I have been struck by the fact that in many instances teachers have failed to recognise even cases well below the border-line of mental defect as feeble-minded, cases which would therefore have escaped notice had their recognition depended entirely on the teacher. In the present area and probably in other areas also—though I have no experience of them—a large proportion of teachers regard mental defect or a congenital low level of intelligence as the *last* cause to be thought of in explaining cases of failure to make normal progress. They tend to assume that bad home conditions, frequent migrations, too large families, are the actual causes of retardation of intelligence, whereas these conditions are often themselves the evidence of, and the result of, a low level of hereditary intelligence in the family. Moreover, children who are very much retarded in intelligence are frequently found advanced a standard or two above that which is really suited to their mental age, though still in a standard below that appropriate to their chronological age.

It is, however, not surprising that many teachers should fail to realise the all-importance of innate or hereditary qualities, and lay undue stress on environment, for the greater part of our educational system is built upon the assumption that all children, with only trifling exceptions, are essentially equal in innate intelligence, that is, in their capacity to receive and profit by an education substantially the same for all. I think it probable, therefore, that the figures I have obtained are far from representing the total. In order to be certain that they are complete, it would be necessary either to subject all children to some form of group test, which would clearly indicate those falling below a certain level of intelligence, and, therefore, requiring individual examination; or that teachers generally should have a more adequate knowledge in the matter of mental defect, so as to be better able to select those children who should be specially examined.

The method of special examination referred to consists of a physical examination, a mental examination, an inquiry into the educational progress, the conduct, temperamental conditions, and social relations of the child, and an inquiry into the family history, including in most cases a visit to the home of the child.

The examination by means of intelligence tests forms a very important part of the investigation. In the present series the Stanford revision of the Binet-Simon tests was used in all cases. For those who are unfamiliar with them a few words on the general principles of these tests may not be out of place. They depend on the fact that native intelligence—or the capacity for making mental acquirements as distinct from the acquirements themselves—develops gradually from birth up to the age of about 16. In bright children the intelligence develops at a quicker rate and reaches a higher level than in average children; while in dull children the reverse is the case. The tests themselves consist of a number of questions, problems, and the like, graded in difficulty, and with a definite standard of success or failure. From the number of successes in these tests it is possible to calculate the mental age of a child, as distinct from his chronological age. In a bright child the mental age will be above the chronological age; in a dull child it will be below. In a strictly average child the two ages will, of course, correspond. The ratio between the mental and the chronological age, the latter being taken as 100, gives a measure of the intelligence of the child, and is known as the intelligence quotient, or shortly as the I.Q. This I.Q., being a measure of native intelligence, is little influenced by ordinary variations of environment or education, and tends to remain constant through all ages. Average intelligence is indicated by I.Q.'s of 90 to 110; superior intelligence by I.Q.'s above 110; and very superior intelligence by I.Q.'s above 120. I.Q.'s of 80 to 90 rank as dull normal; I.Q.'s of 70 to 80 as bordering on mental defect; while I.Q.'s below 70 indicate definite mental defect.

There are factors other than the I.Q. which have to be taken into account in forming a final opinion as to mental defect. It may, for example, be necessary owing to definite abnormalities in conduct or temperament, to regard some cases with I.Q.'s between 70 and 80 as feeble-minded. In the present investigation all cases with an I.Q. below 70 have, with very few exceptions, been classified as feeble-minded, or if below 50 as imbecile. Some cases with an I.Q. between 70 and 80 have been regarded as feeble-minded on the strength of other abnormalities in the mental make-up. I feel that in this latter group more cases should have been regarded as feeble-minded than were actually so classified, and that in these cases abnormalities of conduct will show later that they really belong to the feeble-minded group. As indicated above, an I.Q. of 50 has been taken as the dividing line between the feeble-minded and the imbecile groups. The I.Q. is, of course, no guide in the diagnosis of moral imbecility, except in so far as a moral imbecile is by definition distinct from a feeble-minded person or an imbecile. In some low-grade cases also anything like an intelligence test is clearly quite out of the question. It is possible that, when adults are considered, the above-mentioned limits for the I.Q. are not strictly accurate, but as in the present investigation only children were examined by this method, any difficulty here need not concern us.

Before concluding these remarks on diagnosis I should like to emphasise the fact that, in order to obtain a satisfactory picture of a child specially examined, it is necessary to take into consideration not only the I.Q. but also facts from all available sources as to the behaviour of the child in relation to its environment, the nature of that environment, and the type of family of which the child is a member.

Statistical Results.

The total number of school children which came under review was 4979. This number was contained in a continuous area comprising part of the county of Wiltshire. A municipal borough, which is situated in the area, but which is educationally autonomous, was not included; nor was a similarly situated urban district with a population of 5500, the schools in which I have only recently taken over. The girls' and infants' schools of a second urban district with a population of 2000 were also excluded, as they are not inspected by me. With the exception of the boys' school in the last-named district, which has a number of about 110 on the roll, all the remaining schools are included in five rural districts with a total area of 373 square miles, and a total population of all ages of 36,243 in 1921. The area concerned is therefore very sparsely populated, and consists of scattered villages, in which the predominant occupations are agricultural.

The total number of mental defectives of all grades ascertained was 168. Of this number 140, or 83 per cent., have been classified as feeble-minded, and 27, or 16 per cent., as imbeciles, the remaining one being a moral imbecile. Some of the imbecile group have never attended school, and an additional number have been excluded from further attendance. (I have taken no account of a small number of idiots seen from time to time, as such low-grade cases do not always come under my cognisance.) For the reasons stated above it is probable that the number of feeble-minded children ascertained falls short by a good deal of the number that have been actually present during the time under review. I am inclined to think that the numbers found should be increased by anything up to 50 per cent., or even more, in order to obtain the actual numbers that have been present.

This opinion is confirmed by the diagram (to which attention will be called below) showing the distribution of the I.Q.'s of the cases examined and classified as mentally defective. Each rectangle represents the number of cases the I.Q.'s of which fall within limits of five points. It will be seen that in the diagram the highest rectangle corresponds with the group 60 to 64, while that corresponding with the group 65 to 69 is lower. According to the curve of normal distribution, which has been found to be approximately followed, when large numbers of unselected children have been examined, the rectangles should be increasing steeply in height at this point. In the present diagram some part of the irregularity may be due to the comparatively small numbers examined, but part is almost certainly due to the fact that the higher-grade cases are more frequently missed owing to reasons given above, and therefore not included. (This argument is, of course, valid only for I.Q.'s below 70, above which point only a small proportion of those cases actually examined has been included in the diagram, the remainder not having been classified as feeble-minded.) It is probable also that the number of imbeciles is not complete, as the lower grades are not usually sent to school, and their existence is sometimes not known.

In order to obtain an accurate idea of the number of defectives present at any one time in the total school population, certain corrections must be applied to the figures as actually found. Very few defectives are examined by me before they reach the age of 7, and of this small number all but one have now reached that age. Not the total school population, therefore, but that part only which has attained the age of 7 should be taken as the basis of comparison. This number should be brought into relation with the number of defectives between the same ages. Those defectives, therefore, who have now attained the age of 14, the present school-leaving age, must be subtracted from the total number, as well as those defectives who have left the district between the time of examination and the time of writing. As the schools are visited at least every six months, and most defectives are kept under supervision by the Voluntary Association for Mental Welfare, this last number may be taken as accurately known. The corrected figures may be given in tabular form thus:—

Total school population between ages of 7 and 14	3868
Mentally defective children between the same ages at present in district*	116
Imbeciles included in above	19
Feeble-minded included in above	96
Percentage of imbeciles..	0·5
Percentage of feeble-minded	2·5
Percentage of all grades of mentally defective	3·0

* Including one moral imbecile.

Those children who have been sent by the local authority to institutions outside the area are included.

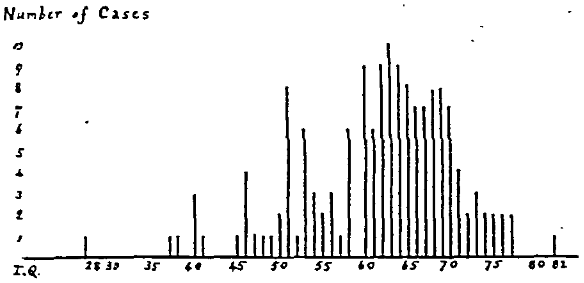
We find, therefore, that there are 3 per cent. of ascertained mental defectives of all grades among children who would ordinarily attend public elementary schools. These figures are as accurate as it is possible under existing conditions to make them. If we are correct in thinking that the percentage ascertained falls considerably short of the real number present, we shall perhaps not be far from the mark in assuming that the true percentage of defectives of all grades lies somewhere in the neighbourhood of 4, or perhaps higher. But, even if one assumes that the lower figures are correct, they are much above those given for towns which have been adequately investigated. Burt, for example, taking an I.Q. of 70 on his own scale as the dividing line, finds that in London 1·5 per cent. of all children (not including in this number the imbeciles) fall below this line and are eligible for special schools. The corresponding figure in the present investigation is 2·5 per cent. The causes of the greater prevalence of mental defect in rural districts will be indicated later.

Distribution of Intelligence among Defective Children.

We may next consider the distribution of intelligence among children ascertained to be defective, and this is best shown by diagrams. The I.Q. was, apart from one or two exceptions to be noted, in all cases carefully taken by myself in accordance with the directions given in Terman's book on the "Measurement of Intelligence." In the majority of cases the longer series of tests was used, in the minority the shorter series of the starred tests only. In these cases the I.Q. may be relied upon as being as exact as careful testing combined with experience in giving the tests can make it. In rather less than half (13 out of 27) of the imbecile group, that is, those whose I.Q.'s fall below 50, the I.Q. was not taken, owing to the fact that it was not possible to test the children, the cause being generally too low a level of intelligence, though in some cases temperamental conditions formed the obstacle. In only one case was there a failure to get the I.Q. in the feeble-minded group owing to the extreme difficulty in securing responses. This was in a girl of nearly 14. I have put her I.Q. as 50 for the purpose of the diagram, but this must be regarded as largely a guess from general considerations. Two other cases were also classified as feeble-minded, which were not examined in sufficient detail to make even a guess at the I.Q. possible. In a few cases the same child was retested after an interval, perhaps two years or more, generally with the result that there was an insignificant difference in the I.Q. In these cases the first result only has been used for the purpose of the diagrams. The detailed distribution of the I.Q.'s is shown in Diagram 1, where all grades of the mentally defective have been included, but not the dull and backward. The case which stands apart from the others with an I.Q. of 82 has been certified as a moral imbecile and is now in an institution; he has a feeble-minded sister with an I.Q. of 70 in the same institution. The distribution under larger groups, namely, five points of the I.Q., is shown in Diagram 2, to which reference has already been made. In the lower line the actual numbers contained in each group are given. As above stated, the figures for the imbecile group represent only about half of the actual numbers examined, the remainder being unclassifiable in terms of the I.Q. A considerable number of children who were found to be classifiable as dull and backward only were also examined in sufficient detail for a determination of the I.Q. to be possible. But as this number represents, of course, only the fringe of the total group of the dull and backward—namely, those who were suspected of mental defect—it is impossible to draw any conclusions from the actual numbers so found or from the distribution of the

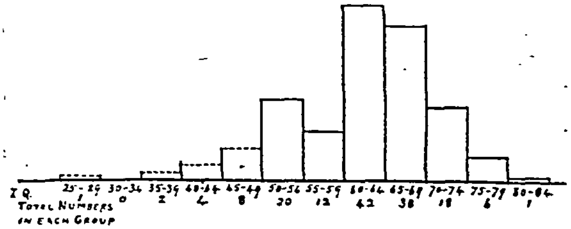
Diagrams Showing the Distribution of the I.Q.'s in the Feeble-minded and Imbecile Groups.

DIAGRAM 1.



The number of cases for each I.Q. is shown by the height of the vertical lines over the base line.

DIAGRAM 2.



The rectangles for the groups below 50 do not represent the total numbers in these groups, as is indicated by the broken line at the top.

I.Q.'s. As might be expected the majority of the I.Q.'s fall into the border-line group of 70 to 80.

In this connexion it is interesting to compare the results obtained in a school where all the children were examined. The school was in the area in question and contained 50 children. Among these unselected children the average I.Q. was 94, which is rather below the average found by Terman, as might on several grounds be expected. The highest I.Q. was 137, and the lowest 47. There were four children who fell below the border-line of mental defect, whose I.Q.'s were 47, 62, 66, and 67. The two last are members of the family reported in detail below.

With regard to the distribution in individual schools of the mental defectives, this is very variable, as would be expected where the schools are small ones. There are in all 80 schools in the area, and the variation is from *nil* in some schools to nearly 10 per cent. in others. Part of the variability is probably only apparent, and due to incomplete ascertainment; of the part that is real some is due to the smallness of the numbers involved; while some is the result of local conditions, including the nature of the employment available, the greater or less desire of the employers to get a good type of employee, and other conditions which determine the type of family to be found in a given locality.

Characters of Mental Defectives.

The problem before us now is to consider the future of these mentally defective children when they reach adult life. The imbecile group are in most cases necessarily incapable of even partial self-support. They either find their way into institutions or remain as burdens on their families. Though to the uninstructed this group forms the most obvious part of the problem of mental defect, it is far less important sociologically than the higher group. What follows will relate almost entirely to the feeble-minded.

Unfortunately I have no personal experience of the problem of mental defect as it exists in towns. It is, I think, generally admitted that a lower level of intelligence is required for self-support in rural areas than in towns, owing to the simpler conditions of environment. Moreover, the opportunities for adopting evil courses are fewer in the country than in the town, and for this reason mental defectives in the country are less likely to come in contact with the police. We might expect to find, therefore, as we actually do find, a larger proportion of mental defectives existing in the country than in the towns; but that many or most of these defectives are capable of more or less complete self-support; and that their mental defect is evidenced, not in most cases by such gross abnormalities of conduct as would be likely to bring them into conflict with the forces of law, but simply by a very low level of intelligence. As a result of this low level of intelligence their self-support tends in many cases to be only partial, and to be supplemented by a greater or less amount of relief from the guardians or from private charity. We find in rural districts, as well as in towns, that the feeble-minded exhibit complete improvidence in marriage and the production of children; their families are usually chronically filthy and neglected, and they are incapable of maintaining any standard of life in the home. The girls frequently become the mothers of illegitimate children.

We must also recognise that, whatever may be the number of actual defectives present, this number represents only the fringe of a very much larger class of subnormal and degenerate individuals, whose capacity for mental development is very limited, whose sphere of usefulness as citizens is correspondingly circumscribed, who may indeed be a burden rather than a help to the community, who tend to transmit to their offspring hereditary qualities of degeneracy and defect, and who, owing to a high reproduction rate, are increasing in numbers relatively to the rest of the community.

Owing to the fact that the present investigation has been in progress for less than three years, it has not been possible to follow children from school up to adult life. But reports on the subsequent progress of a few of the children who have now left school are available. The boys appear in most cases to be employed in helping their fathers or in doing odd jobs on the land; sometimes they are capable of earning a normal boy's wage, but in other cases are unemployable. The girls appear usually to help in the home, and probably the majority will be sent out to service later on.

The best picture of what the feeble-minded child is likely to become may in many cases be obtained from the parents. The father is usually not seen when the home is visited, but in a large proportion of cases the mother appears, from the impressions formed in an interview, which are often confirmed by common repute, to be of very low intelligence. In some cases it is even possible to see in the course of a brief conversation that she is feeble-minded, in which case she exhibits the characteristics above mentioned.

Descriptions of Individual Families.

The following descriptions of individual families will serve to illustrate the characteristics of mentally defective stocks as they exist in a rural area.

H. family. The mother is obviously feeble-minded, almost at first glance, and is generally recognised as such. The father I have not seen, but he is in regular work at a weekly wage of 27s. When I last saw the family a few months ago there were six children, ranging from 15 to a little over a year in age, and a new baby was imminent. Owing to difficulties in getting anyone to undertake the care of the mother during confinement it was suggested that she should have her baby in the workhouse, which, in fact, she actually did. When I first saw the family in 1921 there were three children at school, in a filthy and very offensive condition, and the state of the home corresponded with that of the children. The family has since been under the regular and frequent supervision of the National Society for the Prevention of Cruelty to Children, and conditions have improved somewhat, but are still very bad. The three children at school were examined in 1921 and their condition was as follows: C—, male, aged $11^{9}/_{12}$ years, feeble-minded, I.Q. 63, harmless and well-behaved; will probably have enough intelligence for work on the land. R—, female, aged $9^{5}/_{12}$ years, feeble-minded, I.Q. 51, physically very poorly developed; probably has not enough intelligence to be even partially self-supporting. This child has now been sent to a special residential school. Q—, female, aged $5^{8}/_{12}$ years, dull and backward, bordering on feeble-mindedness, I.Q. 76, too early to give a definite opinion as to whether she may not be ultimately certifiable as feeble-minded. I have not examined the eldest boy or the younger children.

The salient points about this family may be summarised as follows. Mother feeble-minded and quite unfit to look after a family; two at least out of three children examined feeble-minded, and doubtless a proportion of the rest.

B. family. Father employed on a farm; mother not obviously feeble-minded; the children are rather badly kept and appear poorly nourished. There have been 15 children in the family, of whom 13 are now living. The elder boys are employed on the land and the elder girls in domestic service. All the four children at school between the ages of 7 and 14 were examined by me in October, 1922, and their condition found as follows: P—, male, aged $11^{10}/_{12}$ years, I.Q. 61; S—, female, aged $9^{9}/_{12}$ years, I.Q. 64; D—, male, aged $8^{7}/_{12}$ years, I.Q. 68; M—, male, aged $7^{5}/_{12}$ years, I.Q. 65. All these four children are feeble-minded. The head mistress states: "I do not think any amount of teaching will make them normal. They have no reasoning capacity at all." The two elder boys of those examined have exhibited cruel tendencies, and one of them in a composition described an escapade in which he and his brother stamped a duck to death as the funniest thing he had seen in his life. From the headmistress's account it appears that two older brothers, who have now left school, were of the same mental level.

It seems probable, to judge from the children themselves and the family record, that these children will be capable of employment, the boys on the land and the girls in domestic service. But the boys would probably fail in a town environment. The last addition to the family of which I am aware took place just over a year ago, and has since died.

Q. family. The point of interest about this family is that I examined all the children then at school during the course of an examination by intelligence tests. There were five children attending school, of whom the particulars are as follows: L—, female, aged $12^{2}/_{12}$ years, I.Q. 66; F—, male, aged $10^{11}/_{12}$ years, I.Q. 67; C—, female, aged $9^{5}/_{12}$ years, I.Q. 86; T—, female, aged $7^{4}/_{12}$ years, I.Q. 81; O—, female, aged $5^{9}/_{12}$ years, I.Q. 90. There are in addition three other children not yet at school who were not examined, and one who died in infancy. It will be seen that the children tested range in intelligence from a low average through dull and backward to definitely feeble-minded. The home conditions are and have been deplorable, and the children are poorly nourished, dirty, and generally neglected. The family has migrated a good deal. The father is said to be a poor specimen and a bad workman. The mother appears feeble-minded. She has not the intelligence even to alter garments given to her so as to make them fit the children. The schoolmistress attributed the mental retardation of the children to bad home conditions and frequent migrations, but this does not fit the facts of the case so well as that of an hereditary defect appearing to a greater or less extent in the children, apart altogether from the general truth that the I.Q. gives a measure of native intelligence which is but little altered by ordinary variations of environment. C—, for example, has a slightly higher mental age than L— ($8^{2}/_{12}$ years and 8 years), who is nearly three years her senior in chronological age. It is impossible to explain this as the result of the environment, which has acted equally on all the children, whereas it is well known that ancestral characters are inherited to a greater or to a less extent even in children of the same parents.

T. of S. The father of the legitimate children is feeble-minded, a fact apparent on ordinary conversation. Mother is feeble-minded, or perhaps an imbecile. She is quite unable to manage her home, and the children were shockingly neglected, but have improved somewhat under the constant supervision of the N.S.P.C.C. The family, when first seen by me in 1921, consisted of three boys, and there has since been a new baby. Details are as follows: D. S., mother's illegitimate child, aged $12^{7}/_{12}$ years, I.Q. 51, feeble-minded; could not be taught even to read or write at school; since leaving school over a year ago he has done a little work in the fields, but at the time of my last seeing him in April, 1923, was not doing anything. In view of his low level of intelligence it is very doubtful if he will ever be able to obtain regular employment. His intelligence is so low that even now he cannot give the date of the year or reckon change of money. The two other children, J— and B—, aged $7^{6}/_{12}$ years and $4^{6}/_{12}$ years at the time of first examination (now 10 and 7), are both imbeciles, and have been excluded from school. In spite of his mental defect the father appears to be a steady workman.

T. of L. The children of this family are first cousins to the preceding, the fathers of the legitimate children being brothers. In this case I have not seen the father. The mother is possibly feeble-minded, but this is not immediately apparent. There were in 1921 six living children in the family, and in addition two had died, and another baby was expected in a few days. The children at school were first seen by me in September, 1921. There were four, of whom details are as follows: R—, male, aged $13^{5}/_{12}$ years, the mother's illegitimate child, but by the same father as the rest, feeble-minded, I.Q. 53, head circumference 20¼ in.; at school he could not be taught to read anything beyond a few easy words. He has now gone with the family to a different part of the county, and the voluntary visitor of the Association for Mental Welfare reported in March, 1923, that he was able to work, but that his mother's account of his behaviour left no doubt that he was defective, and stated that he was then at work. P—, male, aged 12 years, feeble-minded, I.Q. 61, of higher grade than his brother; head circumference 20¼ in. The same visitor reports that according to his schoolmaster's account he is simply rather backward in his work, owing probably to irregular school attendance and frequent migrations of the family, and that it is absurd to call him mentally defective. S—, female, aged $10^{11}/_{12}$ years, feeble-minded, I.Q. 58, head circumference 20¼ in.; there is nothing in the appearance of the child to indicate mental defect; she has a bright, winning smile, and pleasing manner. She was retested independently by another school medical inspector in July, 1923, and found to have an almost identical I.Q. of 55. The voluntary visitor again reports that according to her schoolmistress's account she is dull in some subjects, but in ordinary life she is quite normal, and expresses his doubt as to whether she is mentally defective. H—, female, aged $8^{4}/_{12}$ years, passed all the seventh year tests and was not further tested; her I.Q. was therefore at least 81 and probably higher, indicating a dull or possibly low average intelligence, not approaching mental defect; head circumference 21 in. I have not examined the younger children.

In this connexion it is interesting to note the extreme unwillingness of teachers and visitor to admit that the backwardness of the two children now at school is due to mental defect, although it brings them well within the border line of feeble-mindedness, and though the visitor admits the presence of one defective in the family. In reference to this the head circumferences are interesting. H—, who is of merely dull or possibly low average intelligence, and who is the youngest of all the children examined, has a larger head circumference than any of the rest, which is up to the average; in the case of each of the others the head circumference is an inch or more below it. The correlation between a small head circumference and low intelligence is, of course, not perfect; but in this case the facts are certainly in favour of the view that the backwardness is due to mental defect, and not to migrations, &c., unless, indeed, it is argued that migrations and irregular school attendance can cause a failure to grow or a shrinkage of the cranium.

N. family. The two youngest children of a family of seven were examined at school in May, 1921. L—, female, aged $8^{10}/_{12}$ years, feeble-minded, I.Q. 66, head circumference 18¾ in.; she was recently under treatment for gonococcal vaginitis mysteriously acquired. E—, male, aged $7^{6}/_{12}$ years, feeble-minded, I.Q. 60, head circumference 19 in. Of the remaining five children, who have now left school, it appears from the mother's description that one is an idiot, another a low-grade feeble-minded, while the other three are stated to be normal. The mother appeared normal in the course of a short interview; the father was not seen. The elder boy mentioned above as being according to his mother's account feeble-minded, recently suffered three months' imprisonment on a charge of indecent assault of a little girl of another family. There can be no doubt that he is feeble-minded, to judge both from his school record and his mother's account, but the question never came before the bench.

I have selected the above families for special report, both because they are some of which I have most complete records, and because they are illustrative of the characteristics of defective families as they exist in a rural area. They are, it is true, some of the worst families with which I have had to deal, but they are typical of many.

The points illustrated may be summarised as follows. In a rural area many undoubtedly defective families are able to obtain a living and bring up a family —after a fashion; on the other hand, they may collapse entirely and drift into the workhouse with their families. The home conditions are frequently very bad and the children badly neglected. Children are produced in unlimited numbers apart from any prospect that the parents will be able to support them. Illegitimacy is a frequent occurrence in such families. Sometimes more serious offences may be committed as the result of mental defect. It will be seen that in some families all the children are imbecile or feeble-minded, in others only a larger or smaller proportion, though the rest are frequently subnormal.

Summary and Conclusion.

The present investigation has shown that, in the rural area examined, there exists among the school population a very high proportion of mentally defective children. The number so ascertained amounted to 3 per cent. of the school population under review, and of this percentage 0·5 per cent. were classified as imbeciles, and 2·5 per cent. as feeble-minded. We also showed reason for thinking that the actual percentage found fell short of the real number present, and that this number was probably somewhere in the neighbourhood of 4 per cent., or even higher. We explained the greater prevalence of mental defect in the rural area investigated, as compared with the usual numbers given for towns, by the lower level of intelligence required for more or less complete self-support in the simpler environment of the country.

By a consideration of typical families we showed that the mentally defective children were in most cases the offspring of generally degenerate stocks, the members of which were incapable of performing in any adequate way the duties and responsibilities of citizenship, but who were not incapable of earning a living of some sort in a rural environment. We thus obtained a picture of the kind of adult into which the mentally defective child was likely to develop.

I am indebted to Dr. C. E. Tangye, county medical officer of Wiltshire, for his permission to publish this report, and also for his advice in its preparation. My thanks are due to Dr. R. C. Monnington, of Salisbury, both for his assistance in the writing of the report and for his constant help and guidance during the whole time that the work on which it is based has been in progress. In addition, I should like to express my gratitude to those numerous teachers who have given me help in the investigations of individual children.

BLINDNESS AND OTHER OCULAR DEFECTS DUE TO NASAL DISEASE.

BY GEORGE W. DAWSON, F.R.C.S. IREL., D.P.H.,
SURGEON TO THE HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE.

THE following cases illustrate how blindness and other ocular lesions may be produced by inflammatory conditions in the nose. In all but the most recent text-books little emphasis is placed on the frequency with which nasal disease may be the cause of ocular defects. One cannot refrain from the reflection that in the not distant past many patients were allowed to lose their sight for want of a timely operation on the nasal sinuses.

Of 600 cases of orbital inflammation Hirchfield found 400 due to sinus disease, and Holmes considers that 40 per cent. of ocular lesions originate in the nose. These figures are not surprising when one considers that, save on its external aspect, the orbit is surrounded by the nasal sinuses which are constantly exposed to infective processes. Dimness of vision, congestion of the conjunctiva, enlargement of the caruncle, œdema of the eyelids, corneal ulcers, iritis, choroiditis, orbital cellulitis, tearing and other lacrymal affections, and optic neuritis may be mentioned among the eye conditions that may be due to nasal disease.

CASE 1.—Woman, aged 31, sent to the Throat Hospital, December, 1917, by Dr. Stroud Hosford, who reported vitreous effusion and opacities. General œdema and turbidity each retina, suggesting septic absorption. There was aching round the left eye for several months, misty vision at times, and some nasal catarrh. The middle turbinates were large; these were removed and some ethmoid cells opened. No pus was seen. Improvement in condition was rapid.

CASE 2.—Woman aged 29. Consulted me in 1919 for slight deafness and pain in the ears. There was a history of some post-nasal catarrh. She had choroiditis in both eyes for four years; at intervals crops of spots appeared on the fundus, some of them becoming permanent, so that by this time she was nearly blind in the left eye. The Wassermann test had been done four times, always negative. No hope of saving the sight was given her either in London or New York, and she had resigned herself to eventual blindness and devoted her time to learning Braille. In spite of the nose appearing normal, but taking into consideration the post-nasal catarrh, the occipital headache, the pain in the ears, and the deep-seated aching behind the eyes, I determined to explore the ethmoid and sphenoidal cavities. The ethmoid on both sides was found diseased, soft, and easily broken down, evidently the seat of a chronic inflammation. The sphenoidal sinuses were opened, but no pus was seen. With the exception of a temporary crop of spots on the right fundus a few weeks after the operation she has had no further eye trouble, and the headache and aching at the back of the eyes have disappeared.

CASE 3.—Man aged 50. In November, 1917, had antra opened and polypi removed. In February, 1922, when in the country, the left eye became red and swollen, and he was treated for erysipelas. When the swelling subsided in a week's time he noticed he was blind in the affected eye. Went to Westminster Ophthalmic. Report: optic disc pale, proptosis, slight conjunctivitis. March 14th: Referred to Golden-square. Eye normal externally, save for slight proptosis; unable to distinguish light from darkness. Operation same day. Ethmoid exposed by external incision. Large hole ¼ inch in diameter found in the os planum, but no pus seen. The ethmoid was cleared out and the sphenoidal sinus opened. No recovery of sight occurred. This case is cited to illustrate with what rapidity the sight may be permanently destroyed—that is, not more than three weeks.

CASE 4.—Woman aged 27. Sent to me in 1916 by Mr. Kenneth Campbell. He reported optic neuritis in each eye. There was a history of influenza two months previously, and for six weeks she complained of pain in the ear, at the back of the eyes, and across the bridge of the nose. On Feb. 26th, the day of the operation, she could only distinguish between light and darkness. The right disc was indistinct and pale; the left showed marked papillitis Elevation 1½ D. Beyond a slight deviation of the septum high up the nose appeared normal. The middle turbinates were not enlarged, and no pus was seen. In order to give more room in a narrow nose the septum was resected; it was thicker and more deviated than it appeared, and its removal allowed one to see the posterior ethmoid region, which was of a uniform dark plum colour. This was found to be almost as soft as butter. No pus was seen. The following day she could see quite well, and in four weeks' time Mr. Campbell reported vision 6/6 in each eye. The sphenoidal sinuses were opened, but appeared healthy. The almost immediate return of vision indicates that the condition was merely due to œdema or pressure on the nerve in the optic foramen.

Nasal Disease in Relation to Optic Neuritis.

Optic neuritis is undoubtedly the most interesting type of eye case that the nasal surgeon has to deal with, whether considered from its direful effect on vision or the dramatic swiftness with which certain cases of blindness are not infrequently restored to sight. In 1892 Caldwell reported a case due to sphenoidal disease, and Krause reported three cases in 1895. Some years later StClair Thomson reported a similar case. It was not until 1912, however, that Onodi, by his classic work on the nasal sinuses, focused attention on the subject. He demonstrated the varying and intimate relations of the optic nerve and nasal cavities, particularly the frequency with which the posterior ethmoidal cell enters into the formation of the optic canal. When this occurs the intervening bone is sometimes as thin and transparent as tissue paper; even this may be absent, so that the sheath of the nerve lies in direct contact with the lining membrane of the sinus. It must not be forgotten that the veins of the nose communicate directly with those of the dura and orbit.

The few post-mortems that have taken place show that the path of infection is by direct continuity of tissue—that is, there is a periostitis and an osteitis, the inflammation spreading thus to the sheath of the nerve. Infection may also occur by way of the veins and lymphatics. In a case of sphenoidal empyema Ortman found that diplococci extended through the periosteum and bone to the dura, and Hajek, in a case of ethmoiditis and meningitis, traced streptococci in the veins which extend from the ethmoid to the dura. One feels that as our knowledge increases many cases formerly labelled as toxic will be found to be due to a more definite pathological entity. Many cases of optic neuritis have now been reported in which nothing abnormal could be detected in the nose, yet on operating on the apparently sound ethmoid it is found to be diseased. This is due to a rarefying osteitis which softens and disintegrates its delicate walls without the formation of pus. Whether this is merely produced by a chronic congestion or is helped by some specific infective organism it is difficult to say, but there is no doubt that it frequently follows a severe cold or an attack of influenza. It would appear that this congestive process has a more penetrating action than that associated with pus.

The nasal surgeon in dealing with optic neuritis must bear in mind other factors which may be the cause of the disease. Syphilis, disseminated sclerosis, tobacco, alcohol, intracranial tumours, and toxæmic conditions, whether due to teeth, tonsils, or intestines, must be carefully investigated. The usual history is that some weeks after an attack of influenza or severe cold there is loss of sight generally in one eye, accompanied by deep-seated pain behind the orbit, occipital headache and perhaps pain in the ears, the eyeballs may be tender on pressure or their movement may be painful, and there may be a history of post-nasal dropping. These symptoms are of the greatest significance and help in diagnosis. Externally the eye is of normal appearance, and sometimes in the early stages nothing abnormal can be seen in the fundus. Characteristic signs, however, soon appear with papillitis and dilated retinal veins.

Permanent blindness may take place in two or three weeks. On the other hand, recovery has occurred after the lapse of several months.

Practical Conclusions.

A skiagram should always be taken. It may reveal an exostosis, a pituitary tumour, or other intracranial disease. It is not reliable or of much help where the sphenoid or ethmoid is concerned, although White, of Boston, says seven out of a series of 20 cases gave a positive photograph. It is well to remember that a sinusitis may be associated with an optic neuritis without having any causal relation (Onodi).

Where there is obvious nasal disease the duty of the surgeon is clear and the sinuses must be explored and laid open, but there is the type of case where no abnormality can be seen in the nose. Nevertheless, in these cases, every other cause of optic neuritis having been as far as possible excluded, there should be no hesitation or undue delay in exploring the ethmoid and opening the sphenoidal sinuses. The danger of doing so is negligible, and should not be considered in view of the gravity of the case. It is the only certain method of finding out the condition of these parts. In a narrow nose I advocate submucous resection of the septum, whether deviated or not. The extra room thus obtained will ensure a better view and enable one to carry out a more complete and satisfactory operation.

EARLY PERICARDOTOMY IN THE TREATMENT OF PERICARDITIS

SECONDARY TO OSTEOMYELITIS OF BONE.

By R. BROOKE, M.R.C.S. ENG.,
HOUSE SURGEON, GUY'S HOSPITAL, LONDON.

PERICARDOTOMY for purulent pericarditis is at present a not infrequent procedure, and with the improvement of modern operative technique will be resorted to more often in future. The mortality from the operation is of necessity very high, so that it is undertaken only as a life-saving measure. The number of recoveries is much greater when the pericarditis occurs in the course of pneumonia or rheumatic fever than when it follows osteomyelitis of bone, the reason not being far to seek, for the latter condition is one manifestation only of a general pyæmia, and metastatic abscesses of the heart muscle itself usually coexist.

Thirty-six cases of pyopericarditis secondary to osteomyelitis of bone have been recorded in which drainage of the pericardium was performed. Recovery after operation took place in two instances only. A few of these cases are tabulated.

Cases Illustrating Importance of Early Operation.

The explanation of this high mortality probably lies in the delay in operative interference. For example, in 20 of the 36 cases pericardotomy was performed three to four or even ten days after fluid in the pericardium had been definitely diagnosed clinically, both by signs and symptoms, and by aspiration.

A good illustration of this is to be seen in the case of G. H. (No. 6 in table). The child was admitted into hospital with an acute osteomyelitis of the left femur of seven days' duration. Immediate operation was performed, and the whole of the shaft of the bone opened up and drained. Eight days after operation the boy showed no sign of improvement, and physical examination of the chest revealed the presence of a pericardial effusion, which was tapped. Turbid serum was drawn off, but at the end of 18 hours no micro-organisms were grown from it. Ten days later the pericardium was again tapped. This time pus was drawn off which, on microscopical examination, revealed the presence of large numbers of *Staphylococcus aureus*. Pericardotomy followed, with death 24 hours later. At the post-mortem examination a pericardium full of pus was found, with a small abscess in the myocardium which had ruptured into the pericardial sac. No other pyæmic foci were present.

The other examples are all similar, in that pericardotomy was delayed until needling of the pericardium revealed a purulent change in the pericardial fluid.

Name.	Duration and site of bone disease.	Length of time after onset before heart lesion.	Date of operation and description of findings.
1. Emma G., aged 14.	Ilium. 7 days.	12 days.	12th day: Pus. *Staph. aureus.* Death.
2. Cecil C., aged 9.	Femur. 2 days.	5 days.	5th day: Pus. *Staph. aureus.* Death.
3. Female.	Tibia. A few weeks.	Asp. twice. Last 5 days before Pr. Fluid sterile.	5 days after asp. Pus + +. No microscopical examination.
4. Female, aged 6.	Rib. Metatarsal. Ill six weeks.	Pm. Asp. 8 days and 4 days after admis. Fluid sterile.	Pr. 10 days after admis. Pus + +. Death.
5. Child, aged 7.	Tibia. Not stated.	Signs of effusion 6th day. 8 days after this pm. tapped. Fluid sterile.	Tapped 10 days later. + + pus. Pr. Death.
6. G. H., aged 11.	Femur. 1 week.	8 days later pm. tapped. Fluid sterile.	18 days later tapped. Pus + +. Pr. third. *Staph. aureus.* Death.

Asp. = Aspiration. Pr. = Pericardotomy.
Pm. = Pericardium.

Turning now to the two records where recovery ensued.

The first occurred in a lad aged 11. Henry P. was admitted into hospital with a two days' history of malaise and fever, with pain and tenderness over the right tibia. Immediate operation was performed, and the shaft of the tibia opened and drained. Eight days later the patient's condition was much the same as on admission, temperature 101° F., pulse 110–120. Physical examination of the chest revealed for the first time the presence of a pericardial rub situated at the base of the heart at the third left costo-sternal junction. The following day the rub had altered in position and character. It was now heard nearer the apex of the heart opposite the costo-sternal junction of the fourth left rib and only faintly. On the third day it had disappeared altogether and there were definite signs of fluid in the pericardium. On the twelfth day after admission the boy's condition was still serious, and the pericardial dullness extended half an inch to the right of the sternum, and to the left as far as the anterior axillary fold. The pericardium was tapped and slightly turbid fluid drawn off. This was thought to contain pus, so that immediate pericardotomy followed. Subsequent bacteriological examination of the fluid demonstrated the surprising fact that it was sterile. Twelve hours afterwards the wound was discharging pus containing a rich growth of *Staphylococcus aureus*. Subsequently, both pulse and temperature subsided rapidly and uneventful recovery took place. At the end of three months the boy was discharged to a convalescent home with the wound healed, and capable of doing a fair amount of active exercise. No signs of adherent pericardium were present.

The second recovery occurred in a boy, George H., aged 12, who was admitted to Guy's Hospital with 24 hours' history of pain in the left calf. On examination marked tenderness was found on deep pressure over the lower end of the left fibula, with swelling, heat, and œdema of the leg. Osteomyelitis of the left fibula was diagnosed, and immediate operation performed. Ten days afterwards he developed a pyæmic abscess in the shaft of the left tibia, which was drained but did badly; so that a Gritti-Stokes amputation was necessary on the fourteenth day. On the twenty-first day a metastatic abscess appeared in the upper end of the shaft of the left humerus. Seven days later a distinct rub was heard over the base of the heart, which disappeared six hours later. Meanwhile, the limits of cardiac dullness were extending and signs of pericardial fluid were now well marked. Twelve hours later the pericardium was needled and slightly turbid fluid evacuated, which on subsequent microscopical examination proved to be sterile. At the time the fluid was thought to be infected and pericardotomy was performed, a rubber drainage-tube being left in situ. Four hours after operation the fluid draining from the tube was distinctly purulent, and when examined microscopically

Staphylococcus aureus was seen in large numbers. Recovery in this boy was uneventful, and he is now walking about the ward. There are no obvious signs or symptoms of adherent pericardium.

In both these cases it will be noticed that the primary disease of bone was operated on at a comparatively early stage, and the pericardium drained before the effusion had become purulent. It is a matter for serious consideration, from this experience, whether it is advisable to perform early pericardotomy in cases of bone disease before the effusion has become purulent. The evidence seems all in favour of so doing.

Danger of Delayed Operation.

In the first place, pericardial effusions occurring during the course of osteomyelitis, if not purulent in the early stages, almost invariably become so later on, for, being pyæmic in origin, there are usually coexisting abscesses in the heart muscle. Besides, the danger of the operation is much less if done early, for the general resistance of the patient is then altogether higher. Further, the mechanical interference with the heart's action caused by the fluid will be removed, and hence the heart and circulation will be in a better condition to deal with the foci of infection. If, on the other hand, the fluid is allowed to remain until it becomes purulent, the outer layers of the heart muscle, bathed in pus, will lose their vitality, with great functional impairment of the whole organ.

Blind needling of the pericardium in more than one case has led to puncture of the heart itself, a dangerous accident; what is more, it is almost impossible to drain a pericardium efficiently by needling, because the bulk of the fluid lies behind the heart in the oblique sinus and is difficult to get at. The heart is thus pushed forward and is directly in the way of the exploring needle. Finally, if the pericardium is drained before pus forms, adherent pericardium is a less likely sequel.

In conclusion, the successful treatment of purulent pericarditis depends first of all upon the early diagnosis and treatment of the bone lesion. If the bone is efficiently drained at an early stage in the disease this complication can often be obviated. On the other hand, if the patient is left too long before active intervention is resorted to, pus may make its appearance in the pericardium at a very early date. There is no definite index as to how long it takes for a pericardial effusion to become purulent. It is very variable and depends upon a variety of factors. In every case of osteomyelitis a sharp look-out should be kept for the appearance of a suction sound at the base of the heart. When it is quite definitely present the heart should be examined at least every six hours, for the rub may change its position and fluid appear quite rapidly. If fluid is present recourse may be had to needling, but as a diagnostic measure rather than as a method of treatment. If fluid is withdrawn then the suggestion is that imr pericardotomy should be performed.

I am indebted to Sir Alfred Fripp for hi permission to publish these cases.

THE TREATMENT OF EPILEPSY WI DIALACE

BY SIDNEY H. HALL EDIN.

IN the treatment of epil the me
important factors is the early r ender
signs. These have been recently
particularly in the psychical
matter shortly, these prodro
alterations in mood and ety,
depression and irritability to th ve
optimism, and evanescent
the daily care of epileptics can, l
observance of these psychic vari
measures to ward off an attack.

epilepsy on a large scale the first principles appear to be a careful dietary and regimen coupled with the treatment of any concomitant organic disease. The physiological and therapeutic effects of bromides are well known. All practitioners, however, find amongst their cases of epilepsy what are termed "bromide failures," usually the class which fills special institutions and colonies.

No one of any experience would think of passing an opinion on the value of any remedy for epilepsy until such remedy had been tried for at least three months. In the cases on which I base the remarks to follow the period of observation has been over six months.

Nature, Dosage, and Effects of Dialacetin.

The drug on which the following reports are based is known as dialacetin, and is stated to be a combination of dial (well known as a most useful hypnotic) with allyl-paracetamino-phenol, the latter element in the combination having analgesic and antipyretic properties. Prof. Cushny, in his "Text-book of Pharmacology and Therapeutics," awards dialacetin a high place in the treatment of epilepsy, stating, inter alia, that it is preferable to luminal. Each tablet contains 1½ gr. of the former and 4 gr. of the latter constituent. It is well to commence with a small dose—say, half a tablet twice daily—and to increase this slowly until the maximum dose has been ascertained. The tablets disintegrate readily in water and their taste is by no means unpleasant. The only other caution to be issued is that if one desires to avert an increase in the number or intensity of the fits the use of any drug which may have been given before must not be stopped, but the dose lessened gradually and small doses of dialacetin given in addition. The dosage of dialacetin is then gradually increased and that of the other preparation reduced until in about three to five days dialacetin may be given alone in such doses as are found to be needed. The greatest success with this preparation is comparable with that attained by most other anti-epileptic remedies—that is, in cases where the seizures occur in cycles or bouts with a fairly long interval between each series of attacks. Here it is fairly safe to anticipate satisfactory results. The caution mentioned earlier to study the psychical state of the patient and to increase the dose slightly when a cycle is imminent well repays attention. Only one case has complained of a feeling of drowsiness after the use of this drug. In all other cases a pleasant psychical change was noted, the patient appearing more cheery and optimistic, in complete contrast to bromide cases. The drug is well tolerated even when taken over a long period. There have been no cases of skin eruption during its use. Sleep is almost always refreshing, and even those patients who are subject to nightmare state that their sleep is undisturbed.

some twitchings. These attacks were very alarming and left him very weak. Several sedative preparations, coupled with "suggestive" treatment, were tried without much effect, but with dialacetin the success was complete and he has had no recurrence for about six weeks. The second case was very similar, except that the child here was 3 years old and only cried herself into a fit when she was thwarted or hurt. She also gradually got bluer and bluer in the face and then became unconscious, frequently losing control of the bladder during the seizure. The case occurred shortly after that described above, and I did not try anything but dialacetin, which proved successful almost at once. The pathology of this condition is inexplicable, but most physicians will have met with such cases at one time or another.

I intend to try this preparation in other spasmodic nerve affections of children such as laryngismus stridulus and tetany, where I think it should prove of great value.

Fulham, S.W.

TRAUMATIC GANGRENE OF THE FOOT

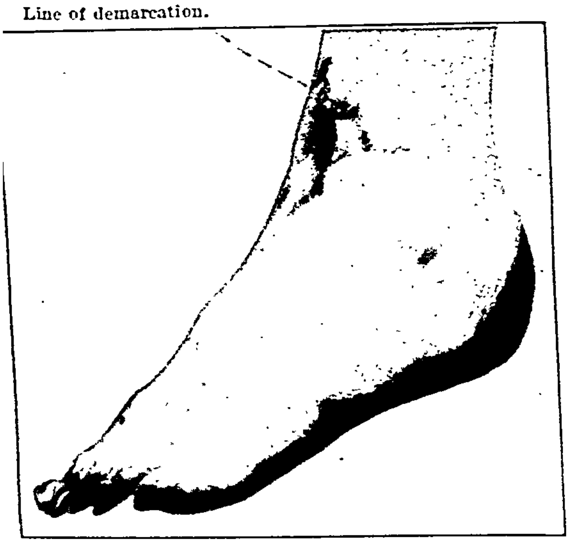
COMPLICATING A FRACTURED FIBULA.

By J. B. G. MUIR, M.B., B.S. LOND., F.R.C.S. ENG.,

SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

FRACTURES of the fibula per se are generally associated with little displacement and are seldom compound, particularly in the upper third of the bone. Involvement of the external popliteal nerve is the only complication of any severity described, and although this may result from the initial trauma, it is usually a later callus involvement of the nerve. Injury to the tibial vessels is of sufficient rarity to merit a description of this case.

FIG. 1.

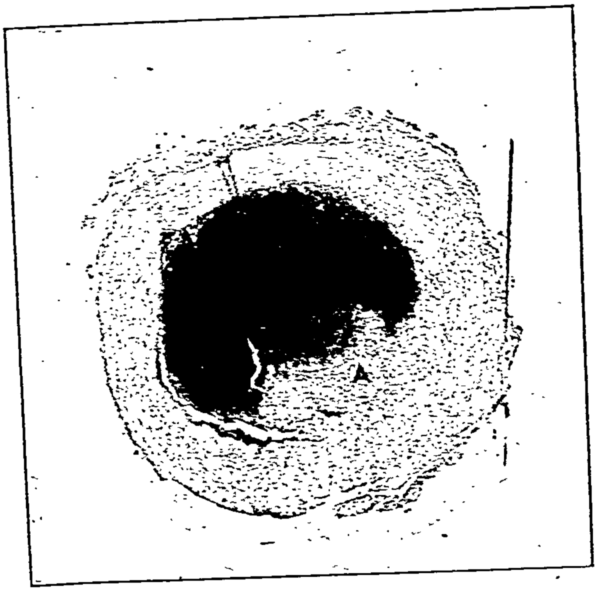


The patient was a country labourer aged 36. "Never a day's illness in his life." Whilst cycling on April 5th, 1924, he was run down by a motor-car and sustained an injury to the left leg, immediately below the knee. He was admitted to the Faversham Cottage Hospital under Dr. A. Kennedy, with considerable bleeding from a punctured wound in the upper third of the leg. The bleeding was so profuse that it was thought that a compound fracture must be present with a large wound; examination, however, revealed only a tiny punctured wound over the junction of the upper and middle third of the left fibula. There was no sign of fracture and a firm dressing was applied to control the hæmorrhage. The following day the temperature was 101° F., and the limb much swollen.

An X ray examination on April 7th showed a fracture in the upper third of the left fibula in good position. On the 9th signs of circulatory obstruction became manifest. The patient complained of coldness of the left foot, which presented a bluish appearance, with anæsthesia of the whole foot. By the 17th a definite line of demarcation had appeared around the ankle-joint immediately above the malleoli. (See Fig. 1.)

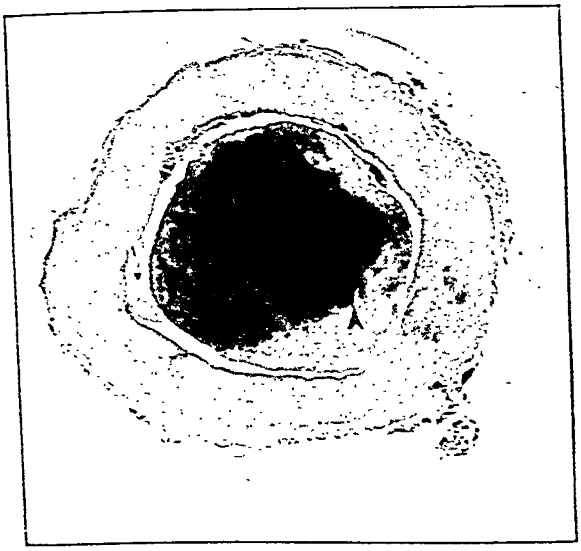
Condition on Admission.—The patient was admitted to Middlesex Hospital on April 20th under Mr. Sampson Handley. He seemed very ill, temperature 103°, pulse 120; the gangrene, however, was definitely of the "dry variety," and strong pulsation was present in the left popliteal artery. On the 26th he suddenly developed a right femoral thrombosis, which quickly resolved. These symptoms suggested the possibility of endocarditis or septicæmia, but a blood culture remained negative, and it appeared to be a postural condition. On May 1st Mr. Handley performed peri-arterial injection of the vaso-motor nerves on the left femoral artery in Hunter's canal, but this had no influence on the gangrene.

FIG. 2.



Section of posterior tibial artery showing organisation of thrombus, commencing at A.

FIG. 3.



Section of anterior tibial artery showing organisation of thrombus commencing at A.

On the 5th I amputated the left leg at the seat of election, using the equal lateral flap method. This low site was chosen because there appeared to be no organic arterial disease

Staphylococcus aureus was seen in large numbers. Recovery in this boy was uneventful, and he is now walking about the ward. There are no obvious signs or symptoms of adherent pericardium.

In both these cases it will be noticed that the primary disease of bone was operated on at a comparatively early stage, and the pericardium drained before the effusion had become purulent. It is a matter for serious consideration, from this experience, whether it is advisable to perform early pericardotomy in cases of bone disease before the effusion has become purulent. The evidence seems all in favour of so doing.

Danger of Delayed Operation.

In the first place, pericardial effusions occurring during the course of osteomyelitis, if not purulent in the early stages, almost invariably become so later on, for, being pyæmic in origin, there are usually coexisting abscesses in the heart muscle. Besides, the danger of the operation is much less if done early, for the general resistance of the patient is then altogether higher. Further, the mechanical interference with the heart's action caused by the fluid will be removed, and hence the heart and circulation will be in a better condition to deal with the foci of infection. If, on the other hand, the fluid is allowed to remain until it becomes purulent, the outer layers of the heart muscle, bathed in pus, will lose their vitality, with great functional impairment of the whole organ.

Blind needling of the pericardium in more than one case has led to puncture of the heart itself, a dangerous accident; what is more, it is almost impossible to drain a pericardium efficiently by needling, because the bulk of the fluid lies behind the heart in the oblique sinus and is difficult to get at. The heart is thus pushed forward and is directly in the way of the exploring needle. Finally, if the pericardium is drained before pus forms, adherent pericardium is a less likely sequel.

In conclusion, the successful treatment of purulent pericarditis depends first of all upon the early diagnosis and treatment of the bone lesion. If the bone is efficiently drained at an early stage in the disease this complication can often be obviated. On the other hand, if the patient is left too long before active intervention is resorted to, pus may make its appearance in the pericardium at a very early date. There is no definite index as to how long it takes for a pericardial effusion to become purulent. It is very variable and depends upon a variety of factors. In every case of osteomyelitis a sharp look-out should be kept for the appearance of a suction sound at the base of the heart. When it is quite definitely present the heart should be examined at least every six hours, for the rub may change its position and fluid appear quite rapidly. If fluid is present recourse may be had to needling, but as a diagnostic measure rather than as a method of treatment. If fluid is withdrawn then the suggestion is that immediate pericardotomy should be performed.

I am indebted to Sir Alfred Fripp for his kind permission to publish these cases.

THE TREATMENT OF EPILEPSY WITH DIALACETIN.

BY SIDNEY H. HALL, M.D., C.M. EDIN.

IN the treatment of epilepsy one of the most important factors is the early recognition of prodromal signs. These have been recently considerably extended, particularly in the psychical sphere. Putting the matter shortly, these prodromal signs vary from alterations in mood and manner, from extreme depression and irritability to the heights of gaiety, optimism, and evanescent brilliance. Those who have the daily care of epileptics can, by a due and keen observance of these psychic variations, often take measures to ward off an attack. In the treatment of epilepsy on a large scale the first principles appear to be a careful dietary and regimen coupled with the treatment of any concomitant organic disease. The physiological and therapeutic effects of bromides are well known. All practitioners, however, find amongst their cases of epilepsy what are termed "bromide failures," usually the class which fills special institutions and colonies.

No one of any experience would think of passing an opinion on the value of any remedy for epilepsy until such remedy had been tried for at least three months. In the cases on which I base the remarks to follow the period of observation has been over six months.

Nature, Dosage, and Effects of Dialacetin.

The drug on which the following reports are based is known as dialacetin, and is stated to be a combination of dial (well known as a most useful hypnotic) with allyl-paracetamino-phenol, the latter element in the combination having analgesic and antipyretic properties. Prof. Cushny, in his "Text-book of Pharmacology and Therapeutics," awards dialacetin a high place in the treatment of epilepsy, stating, inter alia, that it is preferable to luminal. Each tablet contains $1\frac{1}{2}$ gr. of the former and 4 gr. of the latter constituent. It is well to commence with a small dose—say, half a tablet twice daily—and to increase this slowly until the maximum dose has been ascertained. The tablets disintegrate readily in water and their taste is by no means unpleasant. The only other caution to be issued is that if one desires to avert an increase in the number or intensity of the fits the use of any drug which may have been given before must not be stopped, but the dose lessened gradually and small doses of dialacetin given in addition. The dosage of dialacetin is then gradually increased and that of the other preparation reduced until in about three to five days dialacetin may be given alone in such doses as are found to be needed. The greatest success with this preparation is comparable with that attained by most other anti-epileptic remedies—that is, in cases where the seizures occur in cycles or bouts with a fairly long interval between each series of attacks. Here it is fairly safe to anticipate satisfactory results. The caution mentioned earlier to study the psychical state of the patient and to increase the dose slightly when a cycle is imminent well repays attention. Only one case has complained of a feeling of drowsiness after the use of this drug. In all other cases a pleasant psychical change was noted, the patient appearing more cheery and optimistic, in complete contrast to bromide cases. The drug is well tolerated even when taken over a long period. There have been no cases of skin eruption during its use. Sleep is almost always refreshing, and even those patients who are subject to nightmare state that their sleep is undisturbed.

One would indeed be foolish to claim that dialacetin would *cure* epilepsy; the drug which will accomplish this has yet to be found. But my experience has been that under its use major attacks have been both reduced in violence and frequency and, though it is perhaps early to speak of a lessened mental deterioration in such cases, I am fairly confident that this will be another result. Prima facie one is justified in anticipating this. The only class of case where the remedy named has been a little disappointing was where transient loss of consciousness was the chief or only manifestation; and my experience has always been that treatment of any kind is not helpful in these. My observations are based on the records of 52 cases, and in my opinion justify a much more extended trial of this remedy.

I have used dialacetin, though not in a great number of cases, in nervous manifestations in young children. Two of such cases are of interest. In the first a boy, aged 2 years, with a history of "convulsions" in infancy, there used to be definite convulsions every time he cried. He was a spoilt child, and when he got worked up to the crying point he used to hold his breath, become purple in the face, and then pass into a state of unconsciousness with some twitchings. These attacks were very alarming and left him very weak. Several sedative preparations, coupled with "suggestive" treatment, were tried without much effect, but with dialacetin the success was complete and he has had no recurrence for about six weeks. The second case was very similar, except that the child here was 3 years old and only cried herself into a fit when she was thwarted or hurt. She also gradually got bluer and bluer in the face and then became unconscious, frequently losing control of the bladder during the seizure. The case occurred shortly after that described above, and I did not try anything but dialacetin, which proved successful almost at once. The pathology of this condition is inexplicable, but most physicians will have met with such cases at one time or another.

I intend to try this preparation in other spasmodic nerve affections of children such as laryngismus stridulus and tetany, where I think it should prove of great value.

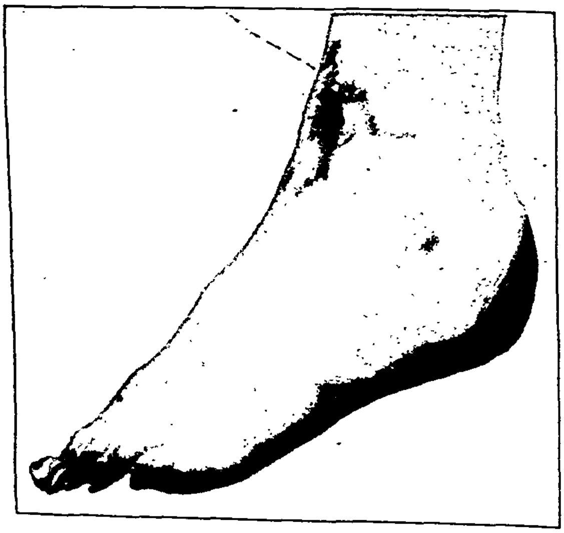
TRAUMATIC GANGRENE OF THE FOOT

COMPLICATING A FRACTURED FIBULA.

BY J. B. G. MUIR, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

FRACTURES of the fibula per se are generally associated with little displacement and are seldom compound, particularly in the upper third of the bone. Involvement of the external popliteal nerve is the only complication of any severity described, and although this may result from the initial trauma, it is usually a later callus involvement of the nerve. Injury to the tibial vessels is of sufficient rarity to merit a description of this case.

FIG. 1.

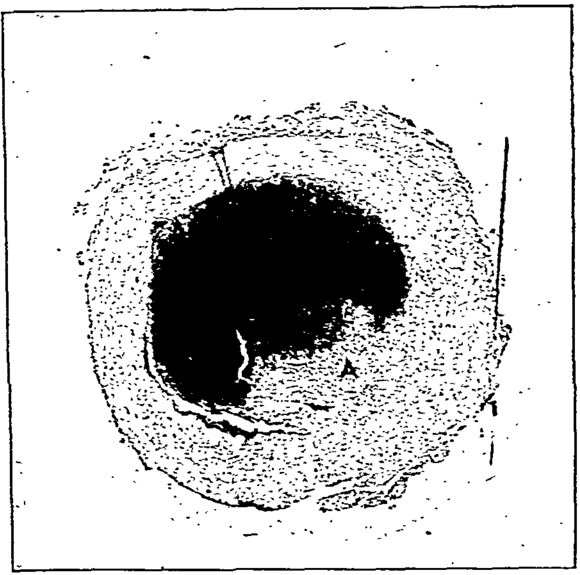


The patient was a country labourer aged 36. "Never a day's illness in his life." Whilst cycling on April 5th, 1924, he was run down by a motor-car and sustained an injury to the left leg, immediately below the knee. He was admitted to the Faversham Cottage Hospital under Dr. A. Kennedy, with considerable bleeding from a punctured wound in the upper third of the leg. The bleeding was so profuse that it was thought that a compound fracture must be present with a large wound; examination, however, revealed only a tiny punctured wound over the junction of the upper and middle third of the left fibula. There was no sign of fracture and a firm dressing was applied to control the hæmorrhage. The following day the temperature was 101° F., and the limb much swollen.

An X ray examination on April 7th showed a fracture in the upper third of the left fibula in good position. On the 9th signs of circulatory obstruction became manifest. The patient complained of coldness of the left foot, which presented a bluish appearance, with anæsthesia of the whole foot. By the 17th a definite line of demarcation had appeared around the ankle-joint immediately above the malleoli. (See Fig. 1.)

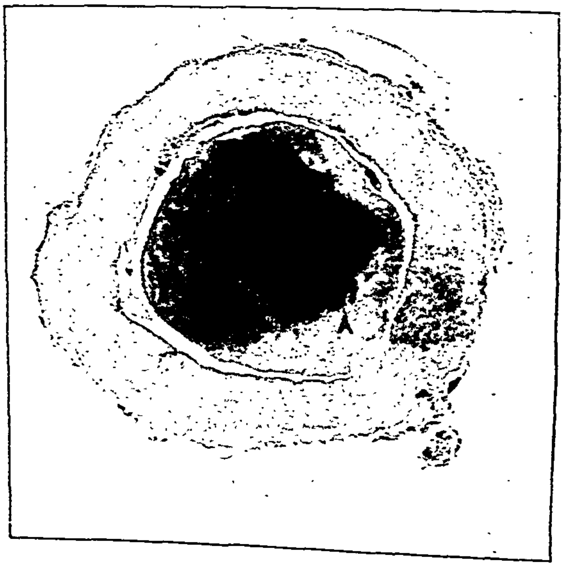
Condition on Admission.—The patient was admitted to Middlesex Hospital on April 20th under Mr. Sampson Handley. He seemed very ill, temperature 103°, pulse 120; the gangrene, however, was definitely of the "dry variety," and strong pulsation was present in the left popliteal artery. On the 26th he suddenly developed a right femoral thrombosis, which quickly resolved. These symptoms suggested the possibility of endocarditis or septicæmia, but a blood culture remained negative, and it appeared to be a postural condition. On May 1st Mr. Handley performed peri-arterial injection of the vaso-motor nerves on the left femoral artery in Hunter's canal, but this had no influence on the gangrene.

FIG. 2.



Section of posterior tibial artery showing organisation of thrombus, commencing at A.

FIG. 3.



Section of anterior tibial artery showing organisation of thrombus, commencing at A.

On the 5th I amputated the left leg at the seat of election, using the equal lateral flap method. This low site was chosen because there appeared to be no organic arterial disease present, which would have influenced the site had the case been one of senile gangrene. During the operation I was surprised to see no bleeding from either the anterior or posterior tibial vessels, which contained partially organising thrombi, although free hæmorrhage occurred from the sural branches of the popliteal. The external popliteal nerve was undamaged. The stump healed by first intention, and patient made an uninterrupted recovery.

Pathological Considerations.

On carefully dissecting the amputated leg a localised, intramuscular extravasation of blood was found around the fracture. This had come from a wound in the first part of the posterior tibial artery, above the origin of the peroneal branch. The proximal part of the vessel contained organising clot which had obviously extended back to the division of the popliteal. At the seat of the fracture the anterior tibial was also injured. This lesion seemed to be more of a bruise which had caused rupture of the inner coat, and the proximal portion of the vessel contained clot. Section of each vessel (see Figs. 2 and 3) showed no arterial disease, the lumens of each containing organising thrombi. The line of demarcation occurring immediately over the ankle-joint would appear to mark the junction of the cutaneous and muscular zone nourished by the sural branches of the popliteal, with the free arterial anastomosis around the ankle-joint from the malleolar and calcaneal branches of the anterior and posterior tibial vessels. The upper third of the fibula is well-clothed and firmly fixed by muscular origins and ligaments, and relatively immobile, so that a spring-like movement of the upper fragment, which had returned to good position and alinement, wide enough to injure both tibial arteries, must be a rare phenomenon.

I have to express my thanks to Mr. Handley for permission to publish this case, and to Dr. Kennedy for his kindness in placing the initial notes at my disposal.

Clinical and Laboratory Notes.

A NEW FORM OF SUTURE MATERIAL.

By Donald McIntyre, M.B. Glasg., F.R.C.S. Edin.,
ASSISTANT TO THE MUIRHEAD PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF GLASGOW.

The production of this material has resulted from dissatisfaction with the present suture material available for closing the uterine incision in Cæsarean section (classical operation). There appears to be a certain element of danger associated with the use of catgut. This results from its slippery surface producing a tendency to loosening of tension or actual unknotting, and from the danger of too early absorption.

On the other hand, unabsorbable material, such as silk, when employed of sufficient thickness to effect satisfactory closure of the wound in the wall of this powerful muscular organ, may lead to minor complications such as adhesions, sinuses, fistulæ, and vesical calculi. Furthermore, it has been shown that a coarse silk suture in the uterine wall may produce a defect in the scar at the site of the suture.

The new material consists of a combination of catgut and silk. The catgut is hardened to 20-day muscle duration, and forms the greater bulk of the suture. Two or more strands of very fine silk are incorporated in the surface. The silk on the surface makes the material easy to handle and eliminates slipping of the knot. The bulk of the suture is absorbed, but the fine strands of silk remain, and so variations in the rate of absorption of the catgut do not constitute a danger.

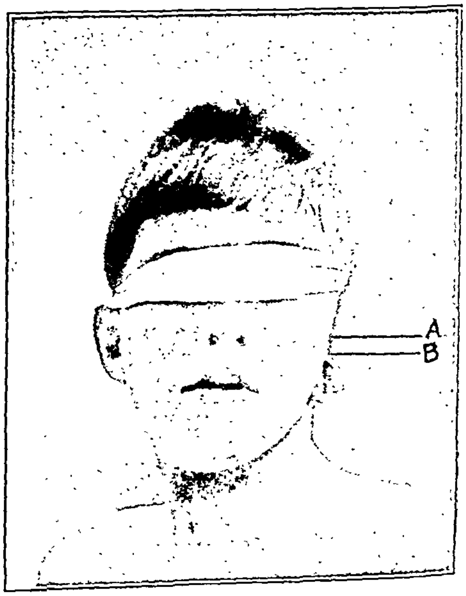
This suture material has been prepared at my suggestion by Messrs. G. F. Merson, Ltd., of Edinburgh. This firm, after a series of careful experiments in combining the two materials, is now able to supply a suture in which the strain when applied is distributed proportionately to the silk and the gut. The silk does not come adrift from the catgut and yet is confined to the surface, being only partially embedded. Messrs. Merson state that "the 'catgut silk-reinforced' may be had in hermetically sealed glass tubes of guaranteed sterility. The sterilising process is carried out during the various stages of manufacture, and after the strings have been tubed, in precisely the same detail as in the case of 'Merson's sterile catgut.' The cost naturally is higher than that of plain catgut, but not so much so as to prove any bar to free use in cases where the ligature is suitable."

The employment of this suture material was first suggested in a paper submitted to the Section of Obstetrics and Gynæcology of the Royal Society of Medicine on June 5th, 1924, when specimens of the material were demonstrated. While originally evolved in connexion with the operation of Cæsarean section, it is suggested that it might be employed with advantage in other surgical procedures.

DEVELOPMENT OF AURICLE ON SECOND BRANCHIAL CLEFT.

By Spencer Mort, M.S., M.D. Glasg., F.R.C.S., F.R.S. Edin.,
SURGICAL DIRECTOR, NORTH MIDDLESEX HOSPITAL; MEMBRE DE LA SOCIÉTÉ INTERNATIONALE DE CHIRURGIE; LATE ASSISTANT TO REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW.

In this case the photograph shows a remarkable example of extensive development of the external ear over the situation of the second gill cleft. The boy was sent to consult me by Dr. Frank Mort, of Middlesbrough, with reference to the deformity, as he was about to go to a public school and felt keenly his appearance. It will be noted that in addition to a malformed and displaced auricle there is a hemiatrophy of the left side of the face, and a paresis of the muscles supplied by the left facial nerve. Closer inspection reveals the presence of a dimple above the malformed auricle, representing the true internal ear, which was skinned over and acting efficiently as an organ of hearing (marked A on photograph). The pointer B indicates the situation of the facial nerve crossing after emerging from the stylo-mastoid foramen, and this in development was pressed on slightly by bands of connective tissue. The auricle itself was clover-leaf shaped. Two portions will be seen in the photograph; the third



portion was situated between the two and running horizontally backwards. The picture was taken immediately before operation on a dull day with faulty apparatus, and I was unable to secure a good lateral view.

At the operation I was assisted by Dr. A. W. Gregorson, and remedied the two defects of shape and position as far as possible. This was done by splitting the two anterior portions of the auricle and bringing between them the middle horizontal part, with adjustments and trimming to resemble the shape of the other ear; also by bringing down a flap of skin from the temporal region it was found possible to increase the size of the newly modelled ear, and pull it up to its proper situation. The operation itself was exceedingly troublesome and tedious, but remarkable recovery followed. The facial paralysis immediately improved, and in six days the patient was able to go home. Since then I have been informed that the ultimate result is one of very material æsthetic improvement. The affected ear is now smaller than the other, but in general appearance it seems as if it had been a normal ear, damaged by a slight accident, and the patient has no longer to endure the jibes of his school friends. With reference to this condition, I have not seen such a marked example published in any text-book.

Reviews and Notices of Books.

DOMICILIARY TREATMENT FOR PULMONARY TUBERCULOSIS.

Second edition. By F. RUFENACHT WALTERS, M.D., B.S., M.R.C.P. Lond., F.R.C.S. Eng., Medical Director, Crooksbury Sanatorium. London: Baillière, Tindall and Cox. 1924. Pp. 288. 7*s.* 6*d.*

THE first edition of this book was published as recently as 1921, and in his preface to this, the second, edition the author denies himself with rare modesty that self-praise which most authors bestow on themselves when they refer to the necessity for the early publication of a second edition. Modesty, as well as intimate and first-hand knowledge of his subject, is, indeed, one of the characteristics of this book, which is a positively encyclopædic collection of recent work on the treatment of pulmonary tuberculosis. The author has no reliable specific remedy to offer for every case, but, as he points out, it seems a pity "that we should not make a more intelligent use of the many excellent remedies and methods of treatment which we already possess." These remedies and methods of treatment he describes in his book, which is full of such profound truths as the following: "Half the tragedies in tuberculosis are caused by the absence of such a record (an accurate temperature record) or its disregard."

The alterations made in the second edition are at the beginning and end, a general review of the subject being given in an introductory chapter, and an additional chapter being added on the public and social relations of home treatment. We regret to differ from the author over his opinion that "consultants who take a special interest in the disease are fairly unanimous in their opinions as to its causation and treatment . . ." Would that they could be! But they still hold widely divergent views as to such important matters as the influence of heredity on the development of tuberculosis and the source of infection in adult life—the relative importance of endogenous and exogenous infection, and the correctness of the Andvord-Romer teaching that practically every case of pulmonary tuberculosis in adult life is due to infection in childhood. And as for treatment, auto-inoculation is anathema to some authorities and the therapeutic mainstay of others. By not committing himself to a defence of any of the extreme schools of thought, the author has provided as good a guide to the general practitioner as could be expected in our present state of half-knowledge of tuberculosis.

PHYSIOLOGICAL INCOMPATIBILITIES IN DENTAL SURGERY.

Vol. I.: Amalgams. By U. REINECKE, L.D.S. Edin. Cape Town: Townshend, Taylor and Snashall. 1923. Pp. 137. 10*s.* 6*d.*

Mr. Reinecke has written an interesting book from an unusual angle which challenges the long-accepted routine of conservative dentistry. His point of view may be summed up thus. The practice of filling teeth with materials which are chosen for their permanence and stability, regardless of the fact that physiologically they are entirely different from the dental tissue they replace, is wrong and may lead to various local and general disturbances. In this volume he limits his consideration to amalgam, which constitutes the vast majority of fillings. He contends that the metals of which the amalgams are composed may undergo dissociation in the mouth. The metallic ions may penetrate the devitalised dentine and come into contact with the protoplasm in the living dentine. This in turn will become devitalised by the toxic action of the metallic products and eventually lead to death of the pulp. Still further the gum, periodontal membrane, and bone may become damaged and even die as the result of long-continued metallic absorption. The staining of dentine by copper amalgam, which has hitherto been regarded as evidence of its penetration and power to sterilise infected dentine, so far from being an advantage, is, according to Mr. Reinecke, a grave defect. Its caustic action cannot be limited to bacteria in the dentine, but must eventually invade healthy tissue and cause its death. In filling teeth the aim of the dentist should not be the obturation of cavities by hard and unyielding material, but rather to replace the missing dental tissue by a material compatible with the teeth.

This point of view is worth consideration, although it might not be easy to find materials which are physiologically compatible and at the same time durable. It cannot be said, however, that Mr. Reinecke provides much direct evidence for his contentions. The fact that copper can be dissociated and evidently does undergo alteration in the mouth, that it possesses toxic properties, and that the tissues of the body under certain conditions can absorb metallic particles—these points are taken as sufficient evidence that copper amalgam used for filling teeth exerts a gradual toxic effect on the teeth, eventually extending to the gum and thence, maybe, to the body generally. Theoretically, all this is possible, yet the clinical evidence which the author adduces is susceptible of other and perhaps more reasonable explanation. Nevertheless, Mr. Reinecke has done good service in drawing attention to the possibility that in concentrating on the mechanical properties of filling materials we have overlooked defects arising from their incompatibility with the dental tissues.

MYOCARDITIS IN CHILDHOOD.

Myokarditis im Kindesalter. By Dr. MATTHEUS VISCHER. Berlin: S. Karger. 1924. Pp. 87. Gold marks 4·20.

IN this monograph the author has given the first half to a critical review of interstitial myocarditis in children with status thymo-lymphaticus, reported in the German literature, along with other recorded cases of interstitial myocarditis associated with myasthenia gravis, Basedow's disease, and polymyositis in children. The second half consists of an analysis of the post-mortem material at the Basle Pathological-Anatomical Institution over a period of six years. Among 783 post-mortem examinations present, which would have influenced the site had the case been one of senile gangrene. During the operation I was surprised to see no bleeding from either the anterior or posterior tibial vessels, which contained partially organising thrombi, although free hæmorrhage occurred from the sural branches of the popliteal. The external popliteal nerve was undamaged. The stump healed by first intention, and patient made an uninterrupted recovery.

Pathological Considerations.

On carefully dissecting the amputated leg a localised, intramuscular extravasation of blood was found around the fracture. This had come from a wound in the first part of the posterior tibial artery, above the origin of the peroneal branch. The proximal part of the vessel contained organising clot which had obviously extended back to the division of the popliteal. At the seat of the fracture the anterior tibial was also injured. This lesion seemed to be more of a bruise which had caused rupture of the inner coat, and the proximal portion of the vessel contained clot. Section of each vessel (see Figs. 2 and 3) showed no arterial disease, the lumens of each containing organising thrombi. The line of demarcation occurring immediately over the ankle-joint would appear to mark the junction of the cutaneous and muscular zone nourished by the sural branches of the popliteal, with the free arterial anastomosis around the ankle-joint from the malleolar and calcaneal branches of the anterior and posterior tibial vessels. The upper third of the fibula is well-clothed and firmly fixed by muscular origins and ligaments, and relatively immobile, so that a spring-like movement of the upper fragment, which had returned to good position and alinement, wide enough to injure both tibial arteries, must be a rare phenomenon.

I have to express my thanks to Mr. Handley for permission to publish this case, and to Dr. Kennedy for his kindness in placing the initial notes at my disposal.

Clinical and Laboratory Notes.

A NEW FORM OF SUTURE MATERIAL.

BY DONALD MCINTYRE, M.B. GLASG., F.R.C.S. EDIN.,
ASSISTANT TO THE MUIRHEAD PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF GLASGOW.

THE production of this material has resulted from dissatisfaction with the present suture material available for closing the uterine incision in Cæsarean section (classical operation). There appears to be a certain element of danger associated with the use of catgut. This results from its slippery surface producing a tendency to loosening of tension or actual unknotting, and from the danger of too early absorption.

On the other hand, unabsorbable material, such as silk, when employed of sufficient thickness to effect satisfactory closure of the wound in the wall of this powerful muscular organ, may lead to minor complications such as adhesions, sinuses, fistulæ, and vesical calculi. Furthermore, it has been shown that a coarse silk suture in the uterine wall may produce a defect in the scar at the site of the suture.

The new material consists of a combination of catgut and silk. The catgut is hardened to 20-day muscle duration, and forms the greater bulk of the suture. Two or more strands of very fine silk are incorporated in the surface. The silk on the surface makes the material easy to handle and eliminates slipping of the knot. The bulk of the suture is absorbed, but the fine strands of silk remain, and so variations in the rate of absorption of the catgut do not constitute a danger.

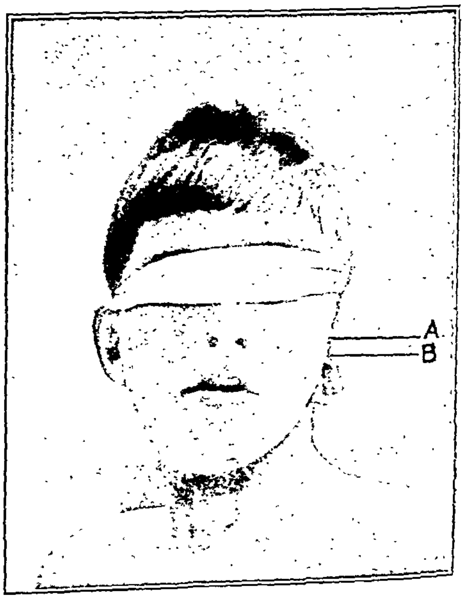
This suture material has been prepared at my suggestion by Messrs. G. F. Merson, Ltd., of Edinburgh. This firm, after a series of careful experiments in combining the two materials, is now able to supply a suture in which the strain when applied is distributed proportionately to the silk and the gut. The silk does not come adrift from the catgut and yet is confined to the surface, being only partially embedded. Messrs. Merson state that "the 'catgut silk-reinforced' may be had in hermetically sealed glass tubes of guaranteed sterility. The sterilising process is carried out during the various stages of manufacture, and after the strings have been tubed, in precisely the same detail as in the case of 'Merson's sterile catgut.' The cost naturally is higher than that of plain catgut, but not so much so as to prove any bar to free use in cases where the ligature is suitable."

The employment of this suture material was first suggested in a paper submitted to the Section of Obstetrics and Gynæcology of the Royal Society of Medicine on June 5th, 1924, when specimens of the material were demonstrated. While originally evolved in connexion with the operation of Cæsarean section, it is suggested that it might be employed with advantage in other surgical procedures.

DEVELOPMENT OF AURICLE ON SECOND BRANCHIAL CLEFT.

BY SPENCER MORT, M.S., M.D. GLASG., F.R.C.S., F.R.S. EDIN.,
SURGICAL DIRECTOR, NORTH MIDDLESEX HOSPITAL; MEMBRE DE LA SOCIÉTÉ INTERNATIONALE DE CHIRURGIE; LATE ASSISTANT TO REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW.

IN this case the photograph shows a remarkable example of extensive development of the external ear over the situation of the second gill cleft. The boy was sent to consult me by Dr. Frank Mort, of Middlesbrough, with reference to the deformity, as he was about to go to a public school and felt keenly his appearance. It will be noted that in addition to a malformed and displaced auricle there is a hemiatrophy of the left side of the face, and a paresis of the muscles supplied by the left facial nerve. Closer inspection reveals the presence of a dimple above the malformed auricle, representing the true internal ear, which was skinned over and acting efficiently as an organ of hearing (marked A on photograph). The pointer B indicates the situation of the facial nerve crossing after emerging from the stylo-mastoid foramen, and this in development was pressed on slightly by bands of connective tissue. The auricle itself was clover-leaf shaped. Two portions will be seen in the photograph; the third



JOURNALS.

BRITISH JOURNAL OF SURGERY.—The July issue contains Sir D'Arcy Power's XIII. Eponym—Syme's amputation.—H. P. Winsbury White discusses the radiographic characteristics of urinary calculi, pointing out that calcium oxalate and calcium phosphate stones show best, the others showing clearly but not so distinctly. The only stones that may fail to give a shadow are those consisting of uric acid and ammonium urate in the bladder.—Kenneth Mackenzie reports a case of a large ventral hernia in the left lower quadrant, which was cured by transplanting the left tensor fasciæ femoris muscle to fill the gap. —Luke Koken Ito describes his experimental results upon the nutrition of articular cartilage and its method of repair. He concludes that damaged articular cartilage is replaced by granulation, which passing through the stages of fibrous tissue and fibro-cartilage becomes true cartilage.—Sir Hugh Rigby contributes a paper on external duodenal fistulæ and discusses the treatment. His results show that the prognosis in these cases is infinitely better than is generally supposed.—Prof. C. C. Choyce analyses 59 reported cases of traumatic dislocation of the hip in childhood, and draws attention to the fact that some of these cases are followed within one or two years by pseudo-coxalgia.—J. P. Buckley discusses the ætiology of the femoral hernial sac, believing that there is no sufficient proof that the pre-formed peritoneal sac is of congenital origin.—A preliminary report, with several excellent colour drawings, is made by A. Tudor Edwards on the use of the thoracoscope in surgery of the chest. He explains its technique and describes the normal and some pathological appearances.—J. Renfrew White describes two bone diseases, one a man of 26 with multiple exostoses and a similar case in a boy of 7 years; in addition he has a case of achondroplasia.—Two simple methods of exposing the humerus and the femur are described by A. K. Henry, which seem to give an easier access to the shafts of these two bones than is attained by other operations.—J. S. B. Stopford, in reporting a case of gangrene of the leg due to obliteration of the popliteal artery, shows how important is the site of the occlusion. Ligature above the origin of superior articular arteries is quite safe, whereas ligature near the inferior articular arteries demands such a complicated system of anastomosis to be opened up that gangrene frequently follows.—T. Twistington Higgins and E. I. Lloyd discuss the subject of mesenteric cysts with reports of two cases.—S. C. Dyke and B. C. Maybury record the results of their experiments on rabbits in attempting to produce an ascending renal infection. They conclude that the production of cystitis fails to give rise to an infection in the kidney, but that infection of the ureter ascended by direct spread along the epithelium.—R. M. Handfield-Jones's Hunterian lecture on retroperitoneal cysts is reported, in which he discusses their ætiology, symptoms, and treatment.—C. P. G. Wakeley publishes his Arris and Gale lecture on some actions of radiations on living tissues.—C. Max Page's Hunterian lecture deals with the surgical treatment of osteo-arthritis. He divides treatment under four headings: (1) Excision of the joint: (2) arthroplasty: (3) erosion of the joint: and (4) synovectomy, and takes the more commonly affected joints in turn and discusses the results.—Hamilton Bailey and G. P. B. Huddy discuss the treatment of extravasation of urine with especial reference to peri-urethral abscess.—K. W. Montsarrat describes a method of extra-peritoneal approach to the ureter through a mid-line sub-umbilical incision and displacement of the peritoneal sac.—The following rare or obscure cases are put on record. (1) Hugh Reid: A Case of Calculus in the Pelvis of an Ectopic Kidney. (2) C. Hamilton Whiteford: An Abnormal First Rib Producing a Supraclavicular Tumour. (3) W. E. Tanner: An Acute Colic Intussusception in a child aged 2½ years.

TROPICAL DISEASES BULLETIN. Sanitation Supplement No. 2, June 30th, 1924.—We have previously commented upon the high scientific value of the Sanitation Supplements issued by the *Bulletin* under the able editorship of Lieut.-Colonel W. Wesley Clemesha, and the present number, which contains nearly 100 pages, maintains a high standard. The information is divided into sections, such as disease prevention, water, food, conservancy, small-pox vaccination, disinfection, infant welfare, reports and statistics, notices and reviews. The supplement is well illustrated with diagrams and photographs, amongst which we note some remarkable pictures taken in the Dutch East Indies of the effect of neosalvarsan upon secondary yaws.

Reports and Analytical Records.

(1) OUABAINE ARNAUD; (2) QUINICARDINE; (3) DIGITALINE.

(From the Laboratoire Nativelle.)

(MESSRS. WILCOX, JOZEAU AND CO., 15, GREAT ST. ANDREW-STREET, LONDON, W.C. 2.)

WE have received from this firm samples of Ouabaine Arnaud put up in different forms and in different strengths, the receptacles bearing full instructions for application and dosage. Ouabaine is a glucoside of the same natural order as strophanthus, and has been described in many places as a substitute for digitalis, but for Ouabaine Arnaud ($C_{30}H_{46}O_{12}$) no such claim is made. The drug, it is suggested, does not replace digitalis preparations but rather completes their effect, much elaborate work having been done to prove the pharmaco-dynamic action of ouabaine as affecting favourably the cardiac systole, while digitalis prolongs the diastole. The drug has the merit also, if the instructions are followed, of being a safe remedy. It is supplied in different forms, as a standard solution 1 in 1000, as tablets of 1/6000 of a grain, and as ampoules of 1 or 2 c.cm. containing ½ mg. of the drug.

From the same laboratory we have received five different preparations of crystallised digitaline, a solution of 1 in 1000, two granular preparations, the granules containing 1/600 and 1/240 gr., and ampoules of different strengths for hypodermic use. Here also full directions are given on the receptacles with the recommended dosage.

We have also received a further sample of tablets of quinicardine, or compressed sulphate of quinidine.

TUBORG LAGER BEER AND TUBORG LIGHT LAGER.

(TUBORG BREWERIES, COPENHAGEN, DENMARK.)

These two beers were bottled at the well-known Danish Tuborg Brewery. When analysed the following results were obtained:—

	Tuborg lager.	Tuborg's light lager.
Specific gravity of wort before fermentation	1056·50°	1043·68°
Present specific gravity	1014·78°	1014·14°
Alcohol per cent. by volume ..	5·4	3·78
Extractives per cent. (total soluble matter)	5·58	4·80
Acidity per cent. as acetic acid ..	0·08	0·07
Original wort solids fermented (per cent.)	60·5	55·2
Fermentable sugars still present (per cent.)	0·13	1·06
Preservatives (salicylic acid and sulphites)	nil	nil

Both these beers, which were in crown-corked bottles of half a pint capacity, were brilliant and free from any sediment. The palate possesses that softness and delicacy so characteristic of the finer kinds of lager beer. The strong hop flavour associated with our English beer is absent. The lager, which is brewed at a slightly higher gravity than Guinness stout or Bass ale, is fermented to a greater extent than the light lager. The absence of preservatives, the low acidity, and general appearance of the two beers made on the new-born and children up to the age of 15, 27 instances of interstitial infiltration of the heart muscle were found. There were 32 cases of status thymo-lymphaticus, and four only of these showed post-mortem evidences of myocarditis. Myocarditis was found in two with status lymphaticus. In all other cases the microscopic examination of the heart revealed nothing abnormal. The author concludes from these observations that myocarditis is not a result of a constitutional anomaly in these cases of status thymo-lymphaticus, and has only an accidental relationship with this disease. True cases of primary acute interstitial myocarditis are reported, and attention is drawn to the interesting clinical picture which they presented. There are no new facts bearing on the ætiology of this disease.

FUNDAMENTAL PRINCIPLES IN TREATMENT.

By HARRY CAMPBELL, M.D., B.S., F.R.C.P. Lond., Senior Physician, West End Hospital for Nervous Diseases; late Physician and Pathologist, North-West London Hospital. London: Baillière, Tindall and Cox. 1924. Pp. 477. 10*s.* 6*d.*

Dr. Campbell does not set out to give a systematic treatise on therapeutics, but provides an agreeable combination of criticism, comment, and advice, held together by a strong thread of common sense, and showing the good qualities conjured up by the phrase "an old-fashioned physician." His opening remarks, for example, on the mental and physical personality of the physician contain such shrewd advice as can only be the result of long experience; they avoid, on the one hand, the tendency to see in the sick person only a collection of test-tube reactions, and on the other, the disposition to forget the scientific aspects of medicine in the attempt to impress one's personality upon the patient. He defends empiricism and bases the use of drugs upon experience rather than upon an assumed knowledge of their physiological action and the morbid processes going on in the body, and whilst saying a good word for fads in strict moderation he points out the dangers of their general application. Perhaps the author deals too gently with our own deficiencies when he indicts the system of *lay* education as the cause of the prevalence of quackery (p. 67), for on the next page he cites the case of a lady who had been an invalid for many years, and had consulted doctor after doctor without any benefit, and yet permanently regained good health after a fortnight's treatment by a quack rubber. Failure in handling such an obviously neurotic patient must surely bear some relation to the fact that psycho-therapy, to which Dr. Campbell devotes six chapters, has no place in the medical curriculum. Practical chapters on housing, fresh air, clothing, exercise, and rest are followed by what is plainly the author's pet subject, for over a quarter of the book is given to the consideration of diet, the teeth, and mastication. A collection of therapeutic aphorisms concludes a book which is marked by an easy style and a wide range of interesting subject-matter.

SPIRITUAL HEALING.

A Discussion of the Religious Element in Physical Health. By the Rev. HAROLD ANSON, M.A. University of London Press. 1923. Pp. 211. 3*s.* 6*d.*

SPIRITUAL healing, constructive thought, practical psychology—all these forms of ascetical exercises are much to the fore nowadays, and this book gives us an account of what spiritual healing really is. As defined by the author on p. 79, it is this:—

> "Spiritual healing rests on the belief that all men are intended to develop towards a standard of perfection which is ultimately attainable, and that they cannot be said to be in perfect health until they have at ained that standard. It is not enough that they should be following their consciences, or that they should be happy and at ease in their present circumstances, or that they should conform to the average ideal of their class or nation. We believe that there is an unseen standard of perfection by which we must all be judged, which we ourselves have the power to evolve through coöperation with God as Spirit."

Again, in his first chapter Mr. Anson says:—

> "We should all probably agree that perfect health ought not merely to be concerned with the purely physical reactions towards life, but ought to aim at placing the person in complete harmony with the *whole* environment—spiritual, mental, and physical—in which he has to live."

He does not put forward spiritual healing as though it were a substitute for medicine or psychology, but claims that it is "rather that which makes the best use of all factors of cure in the proportion appropriate to each particular case." And so it comes about that for spiritual healing a knowledge of God (in so far as the finite can understand the infinite) is necessary, and as our minds and spirits can only express themselves through matter we must look upon matter as "the medium through which the Divine expresses itself."

These are difficult subjects, but Mr. Anson treats of them in a simple and reasonable fashion in his chapters on the Nature of God, Worship, God and the Material World, Man, Why we Call Jesus God, the Spirit, Mind and Body, and Sin. The rest of the book is made up of chapters upon Spiritual Healing in Practice, an Examination of "Christian Science," Auto-suggestion and Prayer, and Miracles. Mr. Anson does not desire that the Church should license special healers, a conclusion to which the Archbishop of Canterbury's Committee on the Ministry of Healing came in November last. Another point on which Mr. Anson insists is the necessity for spiritual directors being properly trained. The Prayer Book lays it down that if any person requires comfort or counsel he should go to his parish priest or "to some other discreet and learned Minister of God's word," but the training of the English clergy in matters of mental direction is by no means profound, and the same thing could be said of the training of medical men.

Mr. Anson's book will be found useful by the layman, the priest, and the medical man, and we advise its study by all who are in any way likely to be called upon to help their fellows in the indicated direction. As a pilgrimage to Lourdes is being advertised to start next month from a London suburb, it would seem that opportunities for giving counsel are not wanting.

HOSPITAL ACCOUNTS AND FINANCIAL CONTROL.

By JOSEPH E. STONE, A.C.I.S., Incorporated Accountant: Accountant to St. Thomas's Hospital. London: Sir Isaac Pitman and Sons, Ltd. 1924. Pp. 160. 21*s.*

Mr. Stone rightly regards accounting, in its widest sense, as one of the essential functions in modern hospital management. Only by careful analysis of the facts relating to its external and internal affairs, and by acting in the light of their interpretation, can any hospital maintain an efficient and economic service. This book reaches a high standard of efficiency which should recommend it to all occupied in the accountancy of our hospitals. Mr. Stone is in favour of a system of accounting by units—that is to say, wards and departments of the hospital—in order to see what the various activities cost and where economies may be effected without impairing efficiency. The extreme care with which the many details have been considered will be highly beneficial to the hospitals which are fortunate enough to possess the necessary staff fully to develop the principles laid down. Particular attention is called to the various sources from which hospitals derive their income, the author having devoted much care and assiduity to the lines on which this work should be conducted at the hospital with which he is associated. Other institutions similarly constituted might well follow the principles here enunciated and the means of attaining them. The price of the book is justified by the value of its contents.

THE LANCET.

LONDON: SATURDAY, AUGUST 16, 1924.

MENTAL DEFECT IN SCHOOL-CHILDREN.

THE proportion of mentally defective persons in the community is not yet a matter of complete agreement. Some estimates of this proportion have been made at different times and in different areas by more or less independent investigators, one of the most recent and most thorough being that of Dr. CYRIL BURT, psychologist to the London County Council, who found a percentage of one and a half among London school-children. The standard adopted has varied with the investigator, and data have usually been incomplete. Dr. G. K. BOWES, in a careful study of children of school age in the rural area for which he is responsible, has discovered so large a proportion of defectives as 3 per cent., and suggests that it should possibly be really 4 per cent. We print on p. 313 his method of ascertainment and some interesting descriptions of individual families. It is probable, as Dr. BOWES himself hints, that the proportion of mentally deficient persons in a rural population is greater than that in a town population, because of the fact that a lower degree of intelligence serves for self-support in a rural area; but on the other hand there appear to be some grounds for thinking that the proportion in the town areas is larger than has been generally stated hitherto. The somewhat disturbing figures suggest the necessity for considering the feasibility of attempting to make a national census of mental defectives. The social and eugenic aspects of the problem of mental deficiency are of sufficient importance to the State to justify such a census in order that the magnitude of the problem may be accurately judged. In the case of children of school age the legal provision and the machinery already exist. The terms of both the Acts of Parliament dealing with mental deficiency make it obligatory upon local authorities to discover all defective children, but it is extremely doubtful whether in any area anything like a complete census is yet available. Local authorities, in particular, who have no special school provision are apt to be slack in the performance of this duty: with others the difficulty is shortage of staff, and, it may be also, lack of experience among the staff in diagnosis of deficiency.

But legal provision and machinery are not enough. There is as yet no definitely fixed standard of what is meant by mental deficiency. Yet in this respect the position to-day is very different from what it was at the time of the Royal Commission on the subject which preceded the passing of the Mental Deficiency Act. Thanks to the efforts chiefly of an army of psychologists, we are now provided with scales of tests, intelligential and educational, which, however imperfect, are of practical value in estimating intellectual capacity, and which in their use allow of greater uniformity in the methods of examiners than was possible before their existence. It is true, of course, that diagnosis of mental deficiency cannot be made by such tests alone—if it were attempted the result would be alarming. But although we are still without generally applicable tests of character, it does not seem impossible to devise some method of "marking" certain social aspects of character, as observed in general behaviour. Dr. S. D. PORTEUS, Superintendent of Special Schools at Melbourne, has indicated the possibilities in this direction in a "social rating scale." A census with a scientific basis of this sort would be of great value. A census based merely on the working definitions of the two existing Acts of Parliament would not be adequate. The vast majority of the cases at present certified under the Mental Deficiency Act are cases of very low grade intellectually—very little higher than the idiots and imbeciles already provided for in the Lunacy Acts; these are by no means so dangerous from a eugenic point of view as many who elude certification, but make as certainly defective and undesirable as parents. At the period of the passing of the Mental Deficiency Act the eugenic aspect had to be slurred over in deference to opposition which emanated more from the heart than the head, but a census that is to be of any practical and scientific value to the nation cannot be thus influenced.

THE PLACE OF CROWNS AND BRIDGE-WORK IN MODERN DENTISTRY.

AT the annual meeting of the British Dental Association at Edinburgh, which has just concluded, Mr. H. W. BENNETTE read a paper on collar crowns in which he unsparingly condemned this method of saving teeth, and in the discussion which followed it was apparent that most of his hearers agreed with him. In considering the evolution of operative dentistry from its lowly beginnings, there are certain methods which stand out as landmarks. Amongst them the use of crowns and bridges represents a notable change in the outlook of the modern dentist. It does not require a very long professional life to have witnessed the gradual evolution of crowns and bridges to their highest point of technical achievement, and their decline in popularity to the present time when so many regard them with disfavour. This decline is not due to the substitution of other methods of greater technical efficiency, but rather to a different outlook on the aims and objects of dental surgery. Even to-day it would be premature to regard the discussion on crowns and bridges as ended, and the obituary notice as read. There are still a large number of dentists both in this country and abroad who use these methods extensively. The pages of dental journals abound in advertisements of various appliances to facilitate the construction of crowns and bridges. A new edition of a popular text-book on crowns and bridges has recently been issued and will doubtless find many purchasers. But although there exists this discrepancy between the academic teaching of dentistry and its practice in many quarters, there can be no doubt that the modern trend is definitely away from these methods of saving teeth.

The reasons which led to the introduction and decline of these operative methods are instructive. Thirty or forty years ago, when great technical advances were beginning to be made in dentistry, the aim of the dentist was to save as many teeth as possible. The local hygiene of the mouth was not entirely disregarded, but it was looked at from a narrow point of view and without much regard to the general health of the patient. Many ingenious methods for splinting loose pyorrhœic teeth were devised on the principle that all teeth which could be used without pain should be retained as long as possible. Relics of this attitude still exist, but they are fast passing away. When teeth were too carious indicate that great care has been exercised in the choice of materials and in the brewing and bottling process.

ORANGE PIERJAC.

(C. A. Labin, Ltd., 53, Piccadilly, London, W. 1.)

This preparation belongs to the well-known type of continental "fruit sirops." It is claimed to be made in France and from fresh fruit and sugar only and to contain no preservatives. The Pierjac had the following composition :—

Specific gravity	1300°
Equivalent to	8 lb. per gallon of sugar.
Sugar (as invert sugar)	79 per cent.
Ash	0·1 "
Acidity (as citric)	1·18 "
Alcohol, gum, glucose, syrup, glycerine, and preservatives (salicylic acid and sulphites)	absent.

These results, together with the presence of a considerable amount of orange pulp, indicate the correctness of the description. That highly refined cane sugar has been employed in this preparation is shown by the low percentage of ash. When mixed with water or soda-water in the proportion recommended Pierjac makes an agreeable beverage with a pronounced but not too strong orange flavour, although to some, especially to adults, the sweetness might be slightly excessive.

"ALOCOL."

(A. Wander, Limited, 45, Cowcross-street, London, E.C. 1.)

This preparation, the full name for which is colloidal hydroxide of aluminium, is supplied in tablet and in powder form, and has claims for consideration in the treatment of disease of the stomach and intestine. As an adjuvant in cases of hyperacidity it has been found valuable in practice. The tablets are supplied in containers of 60 tablets at 3*s.* 6*d.* each. The strength of each tablet is 7½ gr. (0·50 g. of pure "alocol"). They are slightly flavoured and must be broken with the teeth. Their purpose is to make the use of alocol easier for the patient, who can take them at any time and without trouble. "Alocol" powder is supplied in 100 and 250 g. containers at 3*s.* 9*d.* and 7*s.* 6*d.* each respectively. Two tablets should be dissolved in the mouth half an hour before and two tablets half an hour after each meal, unless otherwise directed by the physician.

New Inventions.

A COMBINED ENDO-TRACHEAL PUMP AND SUCTION APPARATUS.

The machine illustrated is an attempt to provide in one apparatus all that is necessary for any type of anæsthesia combined with really powerful suction. It has been constructed by Messrs. Coxeter and Son, Ltd., of 171–175, Pancras-road, London, N.W. 1.

The main features of the apparatus are :—

(1) It is portable, as it is fitted with a wood cover and can be carried by a strap.

(2) It is almost silent in operation. This is due to the motor and pump which are of the Reavell-Moseley type, being direct-coupled without intermediate gearing, in the same case. The rotary pattern pump is much more silent than is the oscillating type, and is almost as efficient.

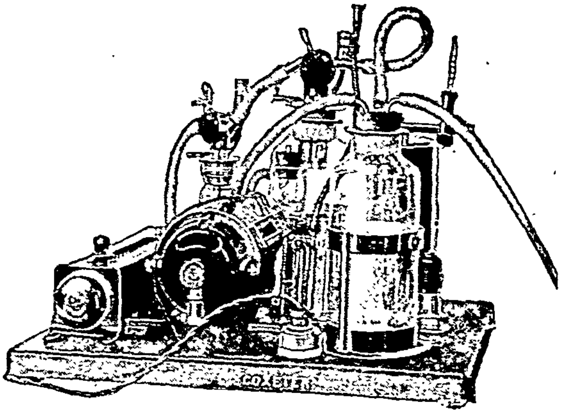
(3) It can be operated on any electric current, direct or alternating from 100–250 volts. This range covers practically every main supply in England, and is effected by employing a double wound motor.

(4) Chloroform, ether, or mixed vapours can be supplied in any proportion at any (measured) temperature and pressure, within fairly wide limits.

(5) An adjustable automatic blow-off prevents the pressure rising beyond any desired value even if the motor is run at full speed during an endo-tracheal administration to provide maximum suction. This feature is of utmost importance in combined machines.

(6) Two filters and two traps are provided between the suction and pressure systems. Furthermore, it is impossible for any liquid particles of anæsthetic to reach the exit tube, however full the bottles may be or however high the pressure.

(7) At full speed the suction is sufficient to aspirate blood clot or thick pus with ease. Thus the apparatus can be used with advantage for dissection tonsillectomies, septum resections, or other proceedings where powerful suction combined with an endotracheal or endo-pharyngeal anæsthesia are necessary.



(8) If the necessary cylinders are available, nitrous oxide–oxygen or ethylene–oxygen can be administered.

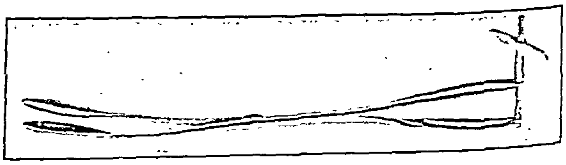
(9) The base-plate of the heater is continued as a support for the ether bottle. Consequently the most concentrated ether vapour can be supplied indefinitely without any freezing in the bottle.

Care has been taken with all the electrical connexions to avoid any possibility of sparks coming into contact with the anæsthetic vapour. This is of vital importance when using ethylene. With nitrous-oxide, the new "dry" gas supplied by manufacturers obviates the necessity for heating the reducing valve, with additional safety from possible explosion.

Regent's Park, N.W. C. Langton Hewer.

A NEW INTRA-UTERINE FORCEPS.

For the removal of retained portions of embryo the blades of the forceps (see figure) are placed in the uterus separately by a method similar to that commonly employed for the application of midwifery forceps. By this means a substantial hold is obtained, rotation can be effected, and "nibbling" small fragments of embryo avoided. The necessary incursions to empty the uterus are reduced to a minimum. Any compression that may be necessary is accomplished by means of the adjustable screw at the extremity of the handles, and as the blades traverse the cervix by lowering this portion of the instrument into the same plane as the handle to which it is attached, an aid to traction is obtained, the handles in the meantime being kept at the requisite degree of apposition by pressure with the left hand of the operator. The lower blade can also be used separately to remove from the uterine wall an early placenta, or other adherent material removable by gross curettage.



The instrument is made in two sizes and can be obtained from H. McClory and Son, 5, Edmund-street, Birmingham.

J. Hargreaves Robinson.
Hon. Surgeon, Royal Maternity Charity of London.

to the gallows: it shows that a dog differs from a man in something more than his anatomical appearance. The parallelism of anatomical and immunological classifications is a field which zoologists might cultivate to advantage.

But in its newer experimental outlook zoology comes much more into relation with medicine, and physiology and pathology have a greater contribution to make to zoology. Prof. Gamble covers a wide field: some of his points only can be mentioned. He gives considerable attention to the remarkable work initiated by Prof. C. M. Child of Chicago on axial gradients. This shows that the head end of an elongated animal is different from the more posterior parts in metabolic intensity and susceptibility to poisons, and that it exerts a variable degree of dominance over the subordinate hinder end. The rate of metabolism diminishes from head to tail, and when the head becomes sufficiently functionally remote from the tail the latter may separate itself off as a new anatomical individual, as in planarians. Normally each cell of an early segmented egg develops into a certain organ or part of an organ. But there is no inevitable predestination in the business. Experimental interference with the arrangement of cells, which under natural conditions is found to be convenient, shows that what the cells of the embryo ultimately become depends much less on what they are than on where they are and how far they come under the influence of the top of the metabolic gradient. The confluence of thought between the experimental embryologist and those who study tumours and their metaplasias is striking.

Another matter in which Prof. Gamble finds food for zoological reflection is the quantitative relation between form and function comprised in the familiar topics of hypertrophy, reserve force, and compensation with the corollary theory that the work of an organ is achieved by its units working by rotation in shifts, thus keeping in good order for functional activity a larger quantity of tissue than is needed in ordinary existence. The relation of these ideas, which have been developed mostly by pathologists, to the biology of live animals is obvious, and we may hope that their consideration by zoologists will lead to a corresponding advance in our understanding of their pathological significance. Prof. Gamble also notices an outcome of factorial genetics of which the possible importance in medicine hardly seems to be realised. Breeding experiments have shown that factors are transmitted in groups, which may be presumed to be the chromosomes. Some combinations of factors, which in themselves have nothing to do with life and death, cannot be actually achieved because the individuals bearing them are not viable. Or they may be achieved under artificial conditions and never occur in nature. There are therefore lethal factors and factors which result in subnormal individuals—phenomena which may have applications to human viability and mortality of very far-reaching importance. We mention only a few examples illustrating the interest of Prof. Gamble's discourse. We would commend its careful perusal to those who think it well to depress the position of biology in the medical curriculum or even eliminate it altogether.

◆

FORMALDEHYDE IN FOOD.

An Interim Report[1] of the Food Preservatives Committee condemns the addition of formaldehyde or any of its derivatives to food or drink. Formaldehyde was discovered in 1867 by A. W. Hofmann as a gaseous product of the flameless combustion of methyl alcohol, and it was soon manifest that the discovery was one of immense industrial importance, for by reason of its very simplicity—the formula is $\mathrm{H{\cdot}CH:O}$—formaldehyde was found capable of reacting with practically any class of organic, and a large number of inorganic, substances. The high solubility of the gas in water (formalin is the name given to a 40 per cent. solution) made its application technically easy. Its prodigious reactivity made it of high value in the coal-tar colour industry; in tanning it was used for making leather hard and firm; it became popular for coagulating rubber latex, for fixing glues and sizes, for waterproofing fabrics by rendering gelatin or casein insoluble, for hardening the gelatin films of photographic plates, and for preserving anatomical museum specimens. Sir Edward Thorpe's "Dictionary of Applied Chemistry," which gives an excellent précis of the industrial applications of formaldehyde, adds ominously: "It is largely used for the preserving of foodstuffs." Now it is difficult a priori to believe that any substance so renowned as a hardening reagent for all kinds of organic products can be suitably applied to food or to the tissues of the human body which is to ingest that food. The Report lays it down categorically that formaldehyde is a powerful protoplasmic poison, exerting an irritant action upon mucous membranes, causing inflammatory changes in the liver and kidneys after prolonged use, combining with tissue proteins in its passage through the body, and retarding digestion by combining with the protein constituents of food. On all these counts formaldehyde is objectionable as a preservative of food. Further than this, there is the dreadful possibility of its use to conceal incipient decomposition; the Report quotes on the authority of Sir George Buchanan a testimonial from a provision merchant attached to a circular advertising preservative containing formaldehyde, which reads as follows: "It is only right that you should know that the treatment you gave my bacon and cheese with ——— which were previously unfit for food are now saleable articles; therefore, you can supply me with a quantity convenient for my use." The addition of formaldehyde to milk is already illegal, administrative action has secured its removal from imported caviare, and the Departmental Committee on Preservatives recommended as long ago as 1901 its prohibition as an addition to any kind of food or drink. Every country which has made legal enactments or regulations regarding the purity of its food-supply has, explicitly or implicitly, prohibited the addition of formaldehyde, and the Committee appointed by Mr. Neville Chamberlain in July, 1923, has no hesitation in recommending that the addition of formaldehyde or any of its derivatives to food or drink should be absolutely and specifically prohibited.

This Committee is not yet ready to report on its wider reference of preservatives and colouring matters in food, and the sweeping condemnation of formalin has arisen on the request for a special report on the Linley process for preserving chilled beef. The Committee found it could not satisfactorily divorce the particular case from the wider question. The object of the Linley process is to enable beef chilled at a temperature of 29° to 30° F. to reach this country from the Argentine or Australasia in good condition and free from moulds. The process, according to its inventor, consists in the single application of formaldehyde gas before shipment, the amount of formalin evaporated being calculated on a basis of two-thirds of an ounce for every 100 cubic feet of space in the chilling room. For some years before the war chilled beef thus treated was imported from the Argentine, although even then the abattoirs controlled by North American firms did not adopt the process and were yet able to export chilled beef successfully. In 1909 an inquiry made by the Local Government Board resulted in an unfavourable verdict on the meat so treated, and a suggestion was made to the traders to limit the use of formaldehyde to the disinfection of the holds before introducing the meat. The amount of formalin in the treated meat was found to vary within very wide limits, and in some cases it had penetrated 30 mm. or deeper into the carcass. The Linley process ceased with the war and the chilled beef now being imported from the Argentine is carried at a to be filled the method of restoring them by an artificial crown of gold or porcelain was introduced. The crown was fastened to the root either by a collar placed over the root and cemented on, or by a post passing into the root canal and secured by cement. It is obvious that, even with the highest technical skill—still more, if the crown is poorly constructed—there is a tendency for food and bacteria to collect round a device of this kind. In the case of collar crowns there is the added factor that there must be a ledge under the gum which collects debris, no matter how well constructed, and must act as an irritant to the gum and periodontal membrane. For this reason many dentists began to condemn this type of crown on the grounds that it predisposed to pyorrhœa, and was an unclean device. This feeling has been steadily growing, until there are few dentists to-day who would not agree that the collar crown is insanitary and should be abandoned. This is not to say that crowns as a whole are to be regarded as an illegitimate form of dentistry. There is still a wide field of usefulness for crowns, but with the proviso that not only must they be constructed with great accuracy, but also that the crown must fit the root edge to edge so that there is no ledge to collect debris. There has been so general a condemnation of crowns by doctors that it is well to make it clear that properly constructed, and in suitable conditions, a crown may be a perfectly scientific and hygienic method of conserving teeth. Any type of crown, however, which involves a collar fitting over the root and extending below the gum margin is, in the opinion of most dentists, a form of conservative dentistry which leads to dental sepsis and should be discarded.

[1] Interim Report of the Food Preservatives Committee on the Treatment of Chilled Beef and Other Foods with Formaldehyde. London: H.M. Stationery Office. 2d.

With regard to bridgework, in so far as the abutments of the bridge which are placed on the supporting teeth are collar crowns, then the condemnation of such crowns applies to bridges also. But there is another factor. Each tooth is capable of slight independent movement under the stress of mastication, through the yielding of the periodontal membrane. This buffer-like action lessens the force of mastication. When two teeth are splinted together, as in a bridge, they must both move together, instead of independently, and the stress to which they are submitted will cause them to become loose. In the case of large bridges which bear a considerable amount of impact during mastication, the strain on the abutments will soon cause the loss of the supporting teeth. In the case of small bridges exposed to little or no strain, this factor may not be serious. Added to this there is also the factor of cleanliness. It is difficult to make so complex a piece of apparatus as a bridge self-cleansing. It tends to gather debris far more than a crown, and may become a veritable trap for filth, well meriting the original condemnation passed on bridges by Dr. William Hunter. If the bridge is removable the foregoing objection may have less weight. Such bridges call for a high degree of technical skill. They may have a legitimate place within narrow limits, but not to an extent which seriously qualifies the general distrust of bridgework as a clean method of tooth restoration. Since the advent of the X ray has shown that pulpless teeth, free from symptoms, may sometimes be infected at the apices, crowns have received additional blame. Sir William Willcox, for instance, has stated that all crowns should be extracted because of the apical infection so often present. There is some confusion of thought here. It is not the presence of the crown which leads to apical infection, but rather the infection of the pulp canal consequent on the death of the pulp. Crowned teeth are usually pulpless, but there is no evidence to show they are more frequently the seat of an apical lesion than pulpless teeth which have been filled. The logical extension of such an attitude would be to state that no tooth which had not a living pulp should be retained in the mouth, and that no treatment involving the root canals should be undertaken. This view has been put forward in America by some, but it does not appear to us that the facts warrant so sweeping a statement or so drastic a limitation of conservative dentistry. The presence of apical infection in some teeth which have been treated is a wholesome challenge to the dentist, for it raises the question as to whether dental technique is sufficiently thorough and scientific to exclude infection from devitalised teeth. The dental profession is fully alive to the gravity of this issue. Already the interest aroused has resulted in a notable improvement in root canal technique which warrants the belief that in the near future infection will be eliminated with certainty in the treatment of diseased pulps.

◆

ZOOLOGY AND MEDICINE.

The presidential address to Section D of the British Association, delivered by Prof. F. W. Gamble at Toronto on August 11th, is of more than usual interest to medicine and its institutes. Taking as his title "Construction and Control in Animal Life," he brings out emphatically the change which in recent times has come over the subject which he professes. Most of last century was occupied with description and classification: "zoology" and "comparative anatomy" were more or less interchangeable terms, and the animation which followed the publication of the "Origin of Species" left the method of inquiry much the same, while it transformed the interpretation of the results. The outlook has now changed again and the dying Darwinian impetus has been replaced by the experimental method. Animals are no longer products which are, within comprehensible periods of time, finished and stable beings; the being, well-being, and becoming of them are no longer problems of statics, but of dynamics. "Regulation" is the keynote of the development of zoological knowledge, whether internally, as by the discovery of the factorial hypothesis, or externally, as in œcological relations. Form has been predominant over function in the formal discipline of zoology; it has been assumed by most people that form has determined function. But function is now coming to the front, zoology and physiology and pathology are fusing their spheres of action, and a good many are wondering whether function does not really determine form. The applications of the older zoology to medical science are obvious enough. It is impossible to investigate the functions and lives of things which have no names, and the intervention of Linnæus was timely. The energy spent on the nicest work in comparative systematics has never been wasted. As the master said, "nomina si nescis, perit et cognitio rerum," and he did well to insist that the live world must be arranged, identified, and put into a form as convenient and lucid as a collection of postage stamps. Every schoolboy who is taken to a museum knows that the being of Anopheles means something different from the being of Culex; the native will learn not to tie up his foreskin for fear of bilharzia when he knows enough about the systematics of snails; it seems likely that some of the most puzzling problems of the distribution and prevalence of plague in India have been solved by the elegant separation of *Xenopsylla astia* from *X. cheopis* by experts in fleas. Pathology has, too, a significant connexion with this side of zoology, through its demonstration of the species specificity of immunological relationships. The identification of a bloodstain by a precipitin reaction does something more than bring a murderer disease—is almost entirely a matter of scientific handling of the product between cow and consumer, and this point is well illustrated in a monograph issued by the Ministry of Agriculture and Fisheries,[1] in which Dr. Stenhouse Williams, of the Research Institute, gives the result of investigation into this problem. During 1916–17 an inquiry into the sources of loss in the milk trade was carried out, and it was found in examining the conditions of supply in two widely separated districts that the chief sources of loss were (1) from milk turning sour before it could be distributed, (2) from splashing in the churns, and (3) from irregularity of supply and demand. Out of a total of 165,000,000 gallons supplied annually by the two districts under examination, the loss due to sour milk was 3,615,441 gallons, representing the large sum of £180,772. The effect of this financial loss is naturally to increase the price of milk to the consumer, and further, there is a very serious wastage of valuable foodstuff. Thus the handling of milk had to be considered in a threefold aspect of bacteriology, mechanics, and economics. In consideration of the first aspect, which involves the keeping qualities of the milk, a comparative series of tests were made in 1916 between the cleanest commercial milk procurable and the average milk from a better class farm. Samples were examined for bacteriological condition and duration of sweetness from the two types of farms. The results showed that where the milk was produced under conditions of strict cleanliness and was cooled immediately it came from the cow to a temperature varying between 45° and 62° F., under all subsequent conditions of temperature the bacteriological counts only rose above 10,000 per 1 c.cm. on three occasions in the course of two years. The average milk, which was sometimes cooled and sometimes not, showed a very different and variable picture. Dr. Stenhouse Williams writes: "It was a revelation that milk which had been properly handled at the farm could maintain so uniform a standard of cleanliness at the end of 24 hours." It was found that clean milk could remain sweet in a cool cellar for an average of 5·8 days, while ordinary milk turned sour after an average of 3·75 days. This question of keeping qualities is one of the greatest importance, as the milk which remains sweet longest is the more marketable commodity. Experience at Reading showed that the poor were willing to buy Grade A (tuberculin-tested) milk, chiefly because its keeping qualities were so much better than that of the milk to which they had been accustomed. There is no surer way of touching the public conscience than through the pocket. If, therefore, clean milk is synonymous with cheaper milk, then we may hope for enthusiasm in the spread of modern hygienic methods in dairying.

THE HOUR OF BIRTH.

IT is an almost universal belief among doctors and midwives that more infants are born by night than by day. Doubtless this belief depends to a large extent on a trick of the memory; we are much more likely to remember an event if it occurred in the night and robbed us of our sleep than if it occurred by day and was one of many thronging incidents following each other with kinematographic speed. To substitute facts for impressions, Dr. O. A. Boije[2] of Helsingfors has recently carried out investigations at his maternity hospital, where he has found that the number of births between 6 in the morning and 6 in the evening was almost exactly the same as the number in the other 12 hours of the 24. His material consisted of 7751 confinements, all of which were terminated spontaneously. There were 3887 in the 12 hours of the day, between 6 A.M. and 6 P.M., and 3861 in the 12 hours of the night. The 24 hours were further subdivided into eight divisions, each of three hours, the divisions being from 6 to 9 in the morning, and so on. The graphic representation of the number of births in each of these eight divisions ran as an almost horizontal line, the difference between the greatest number of births (1059 between 6 and 9 A.M.) and the smallest number (905 between 12 midday and 3 P.M.) being comparatively slight. It has often been taught by the text-books that the hours from midnight to 3 A.M. are those in which a greater number of births are crowded than in any other three-hour period. But in Dr. Boije's material there were only 1018 in this three-hour period of the night. Turning to the hours at which the regular onset of labour begins most frequently, he finds much greater difference than in the case of the completion of labour. The 24 hours of the day being again classified in eight three-hour intervals, it was found that only in 6·5 per cent. of the total did regular labour-pains begin between 12 midday and 3 P.M. From 3 P.M. there was a continuous rise for every three-hour period up to 3 A.M., the maximum being reached in the period 12 midnight to 3 A.M. As great a proportion as 19·6 per cent. of all the labours began at this hour of the night. Almost twice as many labours began during the 12 hours of the night as during the 12 hours of the day, the actual figures being 5084 and 2658 respectively. It would seem that in Finland, at any rate, when labour begins at night, it is usual for a hasty departure to be made to a maternity hospital; whereas when labour begins during the day the departure for a maternity hospital is less precipitate. Consequently many more maternity cases enter hospital by night than by day.

It would seem that, though labour is as often terminated by day as by night, doctors and midwives are more likely to be called on by night than by day to attend confinements.

ANKYLOSTOMIASIS IN THE ARGENTINE.

IN a recent article in *La Semana Médica* Dr. Vaccarezza, Chef de Clinique for Prof. Destefano, deals very fully with the whole question of ankylostomiasis in the Argentine. The disease is widely spread in the north of the country, particularly the province of Corrientes, so much so that 40 per cent. of the recruits from that region show evidence of it on fæcal examination. In some localities practically all the inhabitants are infected. The disease is frequently contracted in infancy, often with very grave results, but after that it is apt to pass unnoticed till adolescence, when the maximum incidence occurs. The blood shows more or less deficiency of red cells, according to the severity, with excess of eosinophiles and often some slight excess of leucocytes. *Necator americanus* is far the most frequent parasite, associated in a large proportion of cases with trichocephalus and others. Dr. Vaccarezza states definitely that the most successful treatment is by carbon tetrachloride in doses of 3 c.cm. for adults; one dose suffices in the majority of cases. If this drug is contra-indicated or fails, the essential oil of chenopodium is the next best; both, he adds, are safer than thymol. As preventive measures the construction of latrines and the use of adequate foot covering are regarded as the most important. The article contains a bibliography of recent Spanish literature on the subject.

CHANGES IN THE COMPOSITION OF THE URINE AFTER MUSCULAR EXERCISE.

THE studies of D. Wright Wilson and some of his colleagues on changes in the composition of the urine after exercise[1] are worthy of record. The effect of short periods of strenuous exercise on the urine was studied by comparing the urine from normal men in a resting condition, collected in ten-minute slightly lower temperature—namely, 27° F. The reason given for desiring resumption is that under present conditions the journey from Australia is too long to permit successful transport of chilled beef to this country without the aid of the Linley process. The Committee considered whether it might not be possible to permit the use of formaldehyde after prescribing a limit for the amount which might be present, say 2 to 3 parts per million in a surface layer of beef 7 to 10 mm. thick; but they decided that control would be difficult, and that similar liberty would have to be given to meat traders in this country. On the whole they came to the conclusion that the true interests of trade would not be furthered by a revival of the practice, and it is gratifying to learn that the undesirableness of using formaldehyde as a preservative is generally recognised by the traders themselves. We are glad of this Interim Report and trust that there may be no delay in taking the step of making formaldehyde illegal in the preservation of foods and drinks.

Annotations.

"Ne quid nimis."

CHARITIES AND THE ENTERTAINMENT TAX

DURING the recent discussion on the report stage of the Finance Bill, Mr. Snowden, Chancellor of the Exchequer, proposed a new form of words for the clause providing that entertainment tax should not be charged on entertainments promoted for certain objects. While, he said, it was necessary to protect the revenue against exploitation of charities by private individuals, he thought, and the House of Commons agreed with him, that any society or institution of a permanent character, established or conducted solely or partly for philanthropic or charitable purposes (or by two or more such societies or institutions acting in combination) when devoting the whole of the net proceeds of entertainment to philanthropic or charitable purposes, should be entitled to claim repayment of the tax, but on the understanding that the whole of the expenses of the entertainment did not exceed 50 per cent. of the receipts. The concession, which is a reasonable one, is very welcome in its effect on entertainments promoted for hospitals and other medical charities.

AN ARRAIGNMENT OF THE BOBAC.

THE tarabagan or bobac is a marmot widely distributed over the uplands of Eastern Siberia and Northern China. In appearance it resembles the bland, inoffensive rodent familiar to all climbers in the European alps, and in America under the name of woodchuck. Nothing except a noisy whistle and an undue appetite for succulent vegetables has been urged against the European and American members of the genus Arctomys, but evidence is now conclusive to incriminate the Asiatic bobac as the carrier of pneumonic plague. This has long been suspected, an early writer on the subject being Dr. M. T. Schreiber, whose article in the Russian *Vratch* of 1907 was published shortly before he himself died of the disease in the Government laboratory near Petrograd. A number of outbreaks in the tarabagan were recorded in his paper, as well as the fact that epizoötics occurred among these beasts without, as he believed, human beings becoming infected. In 1910–11 a medical commission, under the leadership of Prof. Metchnikoff, went out to investigate fatal cases of pneumonic plague then occurring on the Khirgiz steppes, where the place of the bobac is taken by another species of Arctomys known in Russia as the sūslik. The susliks were not found to harbour fleas, although commonly enough a small tick was lodged behind the ear. Next, as a result of the International Plague Conference held in Mukden in April, 1911, the Chinese Government instituted in North Manchuria a plague prevention service under the directorship of Dr. Wu Lien Teh, whose report, read at the International Congress of Medicine in 1913, appeared in extenso in our columns.[1] On the evidence then available Dr. Teh satisfied himself that though the bobac does occasionally suffer from plague, the epizoötic was never extensive and the animal does not play nearly so important a rôle in the spread of plague as did the rat. He considered, indeed, its direct relationship to human plague as negligible, the tarabagan, fortunately, eschewing domesticity. We have just received[2] Volume IV. of the series of reports, in which Dr. Teh returns to the matter of pneumonic plague in relation to the tarabagan and revises his conclusions. Previous observations upon the tarabagan have been made rather by native hunters than by trained medical men, for the Tartars, he says, from the time of Marco Polo have described this beast under the name of Pharaoh's mouse. Hasty deductions may readily be made: the tarabagan often has a deposit of fat in the axilla which is apt to be mistaken, even by practised observers, for the characteristics of pest; unsteadiness of gait hastily regarded as due to plague has now been noted in tarabagans dying of other diseases. Dr. Teh is definitely prepared to state that sporadic outbreaks of plague occurring almost yearly in Transbaikalia, and which on two occasions (1910–11 and 1920–21) invaded Manchuria, causing the death of 60,000 and 9600 persons respectively, do actually owe their origin to the tarabagan. Other rodents are encountered in the country, but no case of human infection has ever been traced to them. The disease exists naturally among tarabagans in both acute and chronic forms and can be produced experimentally in both forms. Attempts to infect animals by ecto-parasites—flies, lice, and ticks—have failed, a prominent difficulty lying in the fact that the tarabagan is no passive laboratory animal, but a strong and vicious creature. In infected animals an acute pneumonic process is quite a common post-mortem finding. Although naturally herbivorous, the tarabagan is apt to devour the carcasses of its mates, and positive transmission has been recorded by this means. Three out of 18 cases showed a chronic or subacute condition with greyish nodules in spleen, lungs, and liver. Dr. Teh considers four possible routes in the transmission of plague from tarabagan to man. Russian observers have long believed that plague in Siberia is caused by the eating of tarabagan flesh, but there is no scientific evidence in support of this view. The possibility of infection from inhalation is remote, for the animal is either shot or trapped, and the hunter is seldom if ever in close contact with the beast in an enclosed space. But hunters do not use gloves; their hands are often chipped, and during skinning operations the plague bacillus may readily gain entrance directly into the circulation through the open wound. There are many records of such infections. Indirect transmission by ecto-parasites from a naturally infected tarabagan has not been yet observed, although Dr. Teh regards it as quite conceivable in view of the cognate work upon the rat-flea in India. Dr. Teh may be regarded as having finally convicted the tarabagan or bobac of being a carrier of pneumonic plague.

THE HANDLING OF MILK.

THE production of clean milk has now been widely recognised as one of the most important factors in a healthy food-supply for the nation, and during the past ten years it is largely to this end that the work of the National Institute for Research in Dairying at Reading (see THE LANCET, July 26th, p. 173) has been directed. The question of clean milk—granted, of course, that the animals are free from disease—is almost entirely a matter of scientific handling of the product between cow and consumer, and this point is well illustrated in a monograph issued by the Ministry of Agriculture and Fisheries,[1] in which Dr. Stenhouse Williams, of the Research Institute, gives the result of investigation into this problem. During 1916–17 an inquiry into the sources of loss in the milk trade was carried out, and it was found in examining the conditions of supply in two widely separated districts that the chief sources of loss were (1) from milk turning sour before it could be distributed, (2) from splashing in the churns, and (3) from irregularity of supply and demand. Out of a total of 165,000,000 gallons supplied annually by the two districts under examination, the loss due to sour milk was 3,615,441 gallons, representing the large sum of £180,772. The effect of this financial loss is naturally to increase the price of milk to the consumer, and further, there is a very serious wastage of valuable foodstuff. Thus the handling of milk had to be considered in a threefold aspect of bacteriology, mechanics, and economics. In consideration of the first aspect, which involves the keeping qualities of the milk, a comparative series of tests were made in 1916 between the cleanest commercial milk procurable and the average milk from a better class farm. Samples were examined for bacteriological condition and duration of sweetness from the two types of farms. The results showed that where the milk was produced under conditions of strict cleanliness and was cooled immediately it came from the cow to a temperature varying between 45° and 62° F., under all subsequent conditions of temperature the bacteriological counts only rose above 10,000 per 1 c.cm. on three occasions in the course of two years. The average milk, which was sometimes cooled and sometimes not, showed a very different and variable picture. Dr. Stenhouse Williams writes: "It was a revelation that milk which had been properly handled at the farm could maintain so uniform a standard of cleanliness at the end of 24 hours." It was found that clean milk could remain sweet in a cool cellar for an average of 5·8 days, while ordinary milk turned sour after an average of 3·75 days. This question of keeping qualities is one of the greatest importance, as the milk which remains sweet longest is the more marketable commodity. Experience at Reading showed that the poor were willing to buy Grade A (tuberculin-tested) milk, chiefly because its keeping qualities were so much better than that of the milk to which they had been accustomed. There is no surer way of touching the public conscience than through the pocket. If, therefore, clean milk is synonymous with cheaper milk, then we may hope for enthusiasm in the spread of modern hygienic methods in dairying.

The article contains a bibliography of recent Spanish literature on the subject.

CHANGES IN THE COMPOSITION OF THE URINE AFTER MUSCULAR EXERCISE.

THE studies of D. Wright Wilson and some of his colleagues on changes in the composition of the urine after exercise[1] are worthy of record. The effect of short periods of strenuous exercise on the urine was studied by comparing the urine from normal men in a resting condition, collected in ten-minute periods, and then, after exercise in running up and down stairs had been introduced, making further collections of urine. The object of the investigation was to learn the rapidity and extent of the response of the kidney to the chemical and physical changes taking place in the organism. There was a marked fall in the urine volume after exercise which could not be overcome by drinking small quantities of water at frequent intervals. A considerable increase in the excretion of acids and the conservation of bases were demonstrated by the rapid increase in the hydrogen-ion concentration, titratable acidity, ammonia, and ratio of ammonia to total nitrogen of the urine. The inorganic phosphates increased in parallel degree to the acid excretion. The values reached a maximum in 20 minutes, and returned to normal in less than an hour. The hydrogen-ion concentration frequently returned to normal more slowly, and the phosphate excretion always fell below normal toward the end of the experiment. There was a marked fall in the chlorides, which apparently was not due to the decreased fluid output or to loss of chlorides in the perspiration. The excretion of chlorides fell to a minimum in 20 minutes after exercise and then returned to normal. There was a considerable fall in the nitrogen excretion, but no characteristic change in creatinine due to exercise. The changes observed in the composition of the urine, when compared with the variations in the composition of the blood observed by Barr and his collaborators, indicate that the kidney responds rapidly and efficiently to aid the neutrality regulation in the body. By similar collections of urine in ten-minute periods in men, the excretion of lactic acid after exercise was determined by Clausen's method. After one or two minutes' strenuous exercise the lactic acid excretion rose from a normal of about 2 mg. in ten minutes to 150 mg. in ten minutes. The excretion reached a maximum within 20 minutes after exercise, and then fell rapidly. There was a return to normal in about one hour.

AYURVEDA.

WE have received a copy of the first issue of the *Journal of Ayurveda*, a monthly periodical published in Calcutta and edited by a Sanscrit scholar who was trained initially in the Western system of medicine. A readable and modest paper on the aims and ideals of Ayurveda by Capt. G. Srinivasa Murti, I.M.S., is followed by a speculative essay on the place of bacteria in the Oriental scheme of medicine. We have next an article on the therapeutics of mica and its medicinal preparations, and material is here supplied for an inquiry by Western pharmacologists. A short history of the Ayurvedic system and a note on its renaissance conclude an interesting journal, to which is appended a report on the Fourteenth Ayurvedic Conference, held at Colombo last April. This magazine forms a curious contrast to such publications as the modernised "Charaka Sambita" and the "Ayurvedic System of Medicine," both published in English a few years ago, in which extravagant claims were put forward for Ayurveda, joined with stupid denunciations of Western medicine. This active hostility to Western medicine alienated the sympathy that the traditional therapy would have received from progressive Western medicine, but now that Ayurvedic medicine is working to use the advances made by modern science it should receive from the West open-minded treatment. Two potent stimuli have recently energised Ayurveda: the Reforms Scheme, and a newly-aroused desire on the part of I.M.S. administrative officers and others to put the system through a full scrutiny. Two inquiries have been held: one by the Government of Madras, the report on which has just been published and is highly interesting and instructive; the other by the Government of Bengal, the report on which is impatiently awaited. The greatest modern champion of modern Ayurveda was the late Sir Pardey Lukis, who, years ago, thought that modern Ayurvedic practice might come to hold an important place in the medical work of India. Medical administration is now a transferred subject, and Indian ministers holding this portfolio in the Provinces have not been slow to foster the indigenous systems of medicine. Allotments have already been made by some Provincial Governments to promote the extension of Ayurveda, for which colleges, hospitals, and dispensaries are being opened in many parts of India. There are over a hundred millions of people in India who cannot get Western medical treatment, and there are many millions who suffer and die without receiving medical care of any kind. The country is so vast that Government is unable to provide for the medical treatment of everyone. We welcome the prospect that many of these unfortunates will be within reach of modern Ayurvedic practitioners and that they will have something beyond charms and incantations to rely upon. For these and other reasons we hope the indigenous system of medicine will receive further encouragement.

THE TEACHING OF HEALTH IN SCHOOLS.

WE had occasion in our issue of August 2nd to notice the booklet on "The Practice of Health" issued under the auspices of the Headmasters' Conference as framing the teaching of a subject of the first importance along lines which were impracticably generous. The matter is dealt with again by Dr. H. O. West, of Margate, in the *Preparatory Schools Review* (June, 1924, p. 53). Enthusiastically in favour of some such regular instruction, he urges that it must be of the simplest character and limited to elementary essentials which are within easy comprehension. A syllabus does not define the standard to which a subject shall be taught, but the one he proposes seems to omit nothing of importance, and is as follows:—

1. The romance of public health. Bygone days, famous names, present opportunity.
2. The air we breathe. Composition, impurities, ventilation.
3. The water we drink. Sources, purity, impure water and disease.
4. The food we eat. Different kinds, use and abuse.
5. The sunlight we need. Rays and their properties.
6. The houses we live in. Garden cities, overcrowding.
7. The refuse we get rid of. Various methods, drainage.
8. The bodies we have. Unity of life, cells and their functions, rest and exercise.
9. The germs we use and those we suffer from. Infection and disinfection, immunity.
10. The diseases we can defeat. Causes, methods, epidemics.
11. The generation to follow. Practical application.

Applied with a sensible discretion, this should be a satisfactory general guide. He also suggests that some, at any rate, of the instruction might be given by the school medical officer rather than the masters, and that a certain amount of hygiene might be incorporated into the literary and historical studies of the pupils. Healthiness and history have not been studied together as they might have been, and there is no doubt that, for example, plague in England from 1348-1667 and the falling death-rate of the nineteenth century are historical factors which have to be taken into serious account in any attempt to understand what went on in these periods. Such a method of treatment also reduces the danger of teaching children to make too much of their personal healthiness; as such a quest per se is hardly an ideal of the highest order.

THE AMERICAN MEDICAL WAR SERVICES.

WHEN if ever the time comes for a general mobilisation of the fighting forces in the United States of America half a million men will be immediately required for the care of the sick in the armies and hospitals. Surgeon-General M. W. Ireland lays down[1] the urgent duties of the medical corps in a general mobilisation as (1) to protect the interests of the country in the medical examination of reservists (a duty at first requiring many medical officers, who are soon available for service elsewhere), (2) to protect the health of the new forces, and (3) to prepare vaccines on the scale required. On the mobilising day the war department will tell the medical department the total force aimed at, and the time allowed for mobilisation—the standard idea being four million men in one year. Hospitals must be quickly ready, for 5 per cent. of the reservists will want hospital treatment at once. Three-quarters of the medical corps, or about half a million in all, will be wanted for the care of the sick. Sanitation is, primarily, the responsibility of the local commander, but technical experts must be provided by the medical corps at once; and the number required will tend to increase as the war goes on. So urgent are the calls of medicine on mobilisation that the war department gives priority to medical personnel over the combatant services, and 45,000 medical men will be required at once, while 20,000 will be called up later, leaving one doctor to 1300 of population. Nurses will be left in about the same proportion. Medical men will be called up not individually, but in units. Next in importance to personnel is material; lists of all equipment for all varieties of service are being completed, and the difficult question of replacement is being faced. Replacement will at first be carried out from the reservists, but there are highly skilled technical experts who will advise the department in war time as to where supplies are to be obtained. Some demands have already been assigned by the Assistant Secretary of War to particular districts. Organisation will be improved by the fact that all the newly passed army medical students were educated in the one school, which, for a quarter of a century, it had been the aim of the medical corps to provide—a school having hospital, museum, and library within the same ring fence, and designed to become in time a noble centre of medical learning.

NEPHRECTOMY IN BILATERAL RENAL TUBERCULOSIS.

A FEW years ago most surgeons would have refused to perform nephrectomy where both kidneys were tuberculous, perhaps they would do so even now. But a good case has recently been made out for removing the most diseased kidney, and the advocate of this course, Prof. G. Ekehorn,[1] of Stockholm, speaks with an experience of about 200 cases of renal tuberculosis coming to operation. It is encouraging to find that renal tuberculosis is, on the whole, seen by the surgeon in an earlier stage than heretofore, and Prof. Ekehorn has observed an appreciable diminution during the last few years in the number of patients coming to him in an advanced stage of renal tuberculosis. But he has seen as many as 27 cases in which the disease was so advanced that he could not carry out all the usual tests, and in five cases not only was catheterisation of the ureters impossible, but he could not even examine the bladder by cystoscopy. The fate of such cases is usually expectant treatment. The course adopted by Prof. Ekehorn was more active; the kidney thought to be least damaged was explored by an operation, and when not found to be too extensively damaged, the more diseased kidney on the other side was removed. In seven cases the operation was confined to exploratory exposure of the kidneys. In the remaining 20 cases the most diseased kidney was removed, the disease having completely, or almost completely, destroyed the kidney in 11 cases and having damaged it extensively in the remaining nine. The wounds on both sides were usually closed completely and without drainage, and though the operations were performed on the same occasion, the patients tolerated them satisfactorily, and in almost every case were better afterwards, as shown by diminution of the bladder symptoms and of the pus in the urine. Indeed, two of the patients were discharged as "well." These patients were operated on in Upsala and Stockholm between 1910 and 1922, and with a view to ascertaining their subsequent fate Prof. Ekehorn addressed inquiries to them in the autumn of 1922. He obtained no answers from five of the 20 on whom nephrectomy had been performed, and he found that ten other patients had died. One of them had lived for six years, another for two, and a third for a year and ten months after the operation. Five were still alive, and two of them were still able to do heavy work, although 12 years had elapsed since nephrectomy had been performed. They had to pass water more than once during the night, but they had no pain or other symptoms, and the urine contained no albumin. A third patient, operated on five years earlier, still had a trace of albumin in the urine and micturated frequently, but he had no pain and could work as before. It is on the strength of evidence such as this that Prof. Ekehorn favours nephrectomy in bilateral renal tuberculosis, when there is clear evidence that the most diseased kidney is largely responsible for fever, pain, and other symptoms.

THE BRITISH DENTAL HOSPITAL.

WE have before us the twelfth annual report of the British Dentists' Hospital (offices, 31, Camden-road, London, N.W. 1), which was founded in 1911 to assist the large class of persons who, while possessing limited means, are unable to pay the ordinary charges of dental surgeons in private practice. At the next annual meeting the name of the hospital will be changed to the British Dental Hospital, which indeed seems desirable, inasmuch as the beneficiaries under the scheme are not the dentists themselves, who act in a purely honorary capacity, but the very large number of patients who are benefiting from the scheme. Small fees on a regular scale are charged for every service rendered, with the result that the hospital pays its way, and the whole work is done not by students but by qualified dental surgeons, numbering at present 37, who must also be members of the British Dental Association. From the outset the work of the hospital has constantly expanded, branch centres have been established taking over the dental work of various official bodies such as that of insurance committees and child welfare centres, tuberculosis patients under the Ministry of Health, and London County Council school-children. Special equipment is maintained for the service of tuberculous patients in the clinics at Battersea, Greenwich, Hampstead, Holborn, Lewisham, Paddington and Wandsworth. At Battersea the increase of patients from maternity and child welfare centres has necessitated an additional half-day a week at the clinic. In Shoreditch a dental clinic has been established at the borough council's new model welfare centre. In the case of one approved society, 50 per cent. of the male membership now has the opportunity of obtaining dental treatment from the hospital. Unfortunately the expense of dentures seriously restricts the supply to mothers from maternity centres, who stand so much in need of them. Prevention stands high among the aims of the hospital, and the staff, besides practising conservative treatment wheresoever practicable, instructs patients in such ways of life as will ensure the least amount of dental disease in the future. At the treatment centres and clinics during 1923 nearly 1900 sessions were held, with a total of over 17,000 attendances and more than 19,000 extractions. There were 3153 fillings, 652 scalings, 1337 dentures supplied or repaired, 3107 cases of advice given, and 706 dressings and root treatments. With these figures, obviously prevention is still in its infancy, and the hospital may be regarded as a plucky and successful attempt to supply part of a great national need.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXIV.—THE TREATMENT OF PSORIASIS.

Unfortunately the treatment of psoriasis is still in a very unsatisfactory position. Probably no great progress will be made till the cause of the disease is known. In many cases the eruption can be removed, if not permanently, at least for some years. In the bad cases, which relapse almost immediately after treatment is stopped, one can only hope to ameliorate the condition without curing it. The treatment may be either external or internal.

External Treatment.

This varies according as the eruption is spreading or stationary. If the eruption is spreading rapidly, is itchy, and shows numerous small recent spots, rest in bed is almost essential. If the patient goes about, the rubbing of the clothes and alterations in temperature tend to increase the spread. Rest in bed slows down the circulation and keeps the skin at an even temperature. All strong applications should be avoided. There is a great temptation to apply some strong ointment to check the eruption; but this never succeeds and simply leads to a further spread. The only way is to soothe the skin till the eruption stops spreading, and not till then is the actual cure begun. An ordinary warm bath should be given daily, and the scales washed off with plain soap and water. If the case is not too acute sulphur baths (potassa sulphurata ℥ii or a packet of sulphaqua to each bath) are often very beneficial. Night and morning plain vaseline or an ointment of 5 parts of soft paraffin and 1 part of hard paraffin should be rubbed in. After a week or ten days the eruption ceases to spread. The baths should be continued, but in place of the vaseline the following ointment should be used: ℞ sulph. præcip. and ac. salicyl aa gr. iiss, lanolin and vaseline aa ℥ss. This is continued as long as there is an improvement. As soon as the improvement ceases the sulphur and salicylic acid are increased to gr. 5 to ℥i (i.e., 1 per cent.), and later to gr. 10 to ℥i (2 per cent.). Finally crude coal tar, painted on very thinly with a stiff brush, should be applied to one area, and allowed to dry on and remain on for 24 hours. If no irritation is caused, the tar should be applied to all the other areas in rotation, doing the arms on the first day, the legs on the second, the front of the body on the third, and so on, taking about five days to paint all the spots. Each spot in this way gets tar for one day and the 2 per cent. sulphur salicylic ointment for the other four days. As the eruption becomes paler the tar should be painted on every fourth day, then every third day, every second day, and finally, when there are only a few spots left, every day. The patient should be kept in bed till the tar is found to be suiting the skin. In men, if the hair is cut short, the scalp can be tarred like the rest of the skin. The tar washes off easily if any grease such as the sulphur salicylic ointment is applied. Wood tars, such as ol. cadini, are not so efficacious as the crude coal tar, besides having the great disadvantage of the strong smell. Cases after treatment with crude coal tar, if thoroughly done, are much less liable to relapse than after any other form of local treatment. The course of treatment takes from eight to ten weeks to effect a cure.

In cases where the psoriasis is extensive but no longer spreading the same treatment should be applied, beginning with the 1 per cent. sulph. salicylic ointment and going on rapidly to the stronger ointment and tar. Chrysarobin ointment is only useful in stationary cases, and should never be used if the eruption is itchy or spreading. It is not suitable for ambulatory cases. When it is used, it should be continued till the spots, which at first turn white, are beginning to show a pink colour again. After the chrysarobin treatment the case should be treated with crude coal tar to prevent recurrences. In many stubborn cases X rays will be found very useful. They should be applied once a fortnight in doses of one-half Sabouraud pastille at a distance of 15 cm. from the centre of the tube. With an ordinary gas tube the exposure is about seven to eight minutes. Usually two applications are sufficient to cause a marked improvement. The rays are especially useful when the eruption affects areas where it is difficult to get ointments into the lesions, such as on the palms and soles and the scalp. When applied to the scalp the dose is not sufficient to bring the hair out. It must be remembered, however, that the eruption does not stay away for any length of time after X rays. The ordinary local treatment must be applied at the same time. Whatever form of local treatment is applied it must be thorough. The scalp must be specially attended to as the disease is frequently left incompletely cured in that area. Unless every spot of disease is removed one cannot hope to prevent a recurrence.

Internal Treatment.

Drugs as a rule are rather unsatisfactory. Arsenic should be tried as Fowler's solution ♏ 5 t.i.d., but is only useful in stationary cases. Larger doses than ♏ 5 are useless, because if the arsenic is pushed till the patient is ill from it the psoriasis will improve temporarily, just as it does if the patient takes any acute illness such as pneumonia. As soon as the patient recovers from the arsenic the eruption recurs. The same remarks apply to thyroid extract. If a result cannot be obtained with small doses no permanent effect will be produced by large doses. The newer arsenical preparations of the arsenobenzol group have been tried, but the results obtained were disappointing. In spreading cases and also in chronic cases salicin gr. 10 t.i.d. is much more likely to do good than arsenic. Alkalies such as pot. citrat. gr. 15, together with mag. carb. gr. 5 t.i.d., are also sometimes useful. The reason for giving alkalies is based on the theory that in psoriasis the skin is too acid. From analogy with seborrhœic conditions, which are somewhat allied to psoriasis, there is some evidence that the skin is more acid than normal. The acne bacillus, which many believe to be identical with the seborrhœa bacillus, will only grow outside the body in an acid medium. Assuming that the skin is more acid than normal in psoriasis, that would explain why some individuals get psoriasis, and others, with less acid skins, do not. It is possible that in psoriasis there is a bowel infection with fermentation and the production of acid. Dieting should be tried in all cases. Psoriasis is certainly not due to any particular food, but good results may sometimes be obtained by cutting out or cutting down certain groups of foods, such as sugars, starches, meats, fats, and acid fruits. Each group should be cut down to the minimum in rotation. If an improvement is going to take place it will show itself within ten days or so. If this form of dieting produces no results, sending the patient to one of the spas, such as Harrogate, to get the bowel thoroughly cleared out does good in some cases. Drinking the waters alone is not usually sufficient; the lower bowel should be washed out by the Plombières douche. Vaccines made from the bowel contents have also been tried, but the results are usually disappointing.

Non-specific Protein Therapy.—In cases where all the above methods fail to give relief non-specific protein therapy may be tried. For this purpose sera, peptone, and sterilised milk have been chiefly used. Of the three, sterilised milk is the one to be recommended. If a foreign serum is used, such as horse serum, there is always the risk, although perhaps not a [illegible] t one. of anaphylactic shock [illegible] tient's own serum is used reactions, and [illegible] the technique which is th[illegible] the [illegible] necessary to prepare the serum. It is difficult in practice to defibrinate the blood, centrifuge it, and keep it sterile. Intravenous injections of sterile peptone are more easily given, but I have never seen any benefit from their use in psoriasis. Intramuscular injections of sterilised milk are easily given and with ordinary care there is no risk. Ordinary fresh cow's milk is used. The milk should be as fresh as possible because, if kept for some hours, the growth of organisms in it produces toxic substances, which cause a marked rise of temperature after the injection. The injections should be given in the forenoon, and that morning's milk should be used. About half a pint of milk, together with a teaspoon, is placed in a small jam-jar, which in turn is placed in a pan containing water. The water is boiled for 15 minutes. The jar is removed from the pan and the "scum" removed from the top of the milk with the teaspoon. Some of the milk is then drawn up into a sterilised Record syringe, and injected with a long needle deeply into the gluteal muscle in the same way as the insoluble salts of mercury are given in the treatment of syphilis. Injections should be given twice a week, and not at longer intervals, so as to prevent any risk of sensitising the patient to the milk. For an adult the first dose should be 2·5 c.cm., the second 5 c.cm., the third 7·5 c.cm., and the fourth 10 c.cm., followed by two more injections of the same dose. Children should have 1 c.cm., 2 c.cm., 3 c.cm., and 5 c.cm. successively. Six injections should give the desired result. There is no object in giving more. Each injection is followed in two to three hours by a marked leucocytosis of the blood, and in three to four hours there may be a rise of temperature, usually to 100°–101° F. The temperature only remains up a few hours, and is not essential for the production of results. The leucocytosis seems to be the essential factor. The fresher the milk the less likelihood is there of any marked rise of temperature. If the temperature reaction is very noticeable the dose of the next injection should not be increased. The only risk connected with the injections is the possibility of the milk being injected direct into a vein and fat emboli being produced. This can be avoided if the piston of the syringe is slightly withdrawn before injecting the milk. If no blood enters the syringe, then it is safe to give the injection. If blood does appear in the syringe it is best to withdraw the needle, empty the syringe, and refill it with milk, and inject in another place. Injections should be given into each buttock alternately.

The above method has only an indirect effect on the psoriasis, and should always be accompanied by local treatment as well. When local treatment is applied it is much more efficacious and rapid in its action than it would be had no injection been given. If chrysarobin ointment is used the same effect is produced in a few days as would have taken three to four weeks in the ordinary course. Similarly tar and other applications act very much more rapidly than usual.

Finally, there is another factor which should never be forgotten in the treatment of psoriasis. The taking of alcohol in any form, even in small quantities, such as in light beers, &c., nullifies the effect of any kind of treatment.

THE INFLUENCE OF FOG ON MORTALITY FROM RESPIRATORY DISEASES.

BY W. T. RUSSELL,
CHIEF STATISTICAL CLERK, NATIONAL INSTITUTE FOR MEDICAL RESEARCH.

(*Communicated by* DR. JOHN BROWNLEE.)

THERE has been much conjecture as to the influence of fog in the causation of deaths from respiratory disease, but so far as I know the analysis of the subject has never been placed on a quantitative basis. Regarding the conditions which produce the city fog, it is generally admitted that the emission of smoke from the chimney of the factory and the home is an important factor. This pollution of the air has been frequently the subject of discussion. Years ago, Evelyn, one of the founders of the Royal Society, endeavoured to focus public opinion on London smoke, which he satirically described as the "hellish and dismal cloud of sea-coal which maketh the City of London resemble the suburbs of Hell," and to counteract its evils suggested "the plantation of pleasantly odorous trees." The late Dr. Russell, of Glasgow, wrote a strong condemnation of smoke and its ill-effects, and the passage deserves reproduction in its entirety.

> "Whenever the scavenging of the air is interrupted by calms, so that smoke products accumulate, the atmosphere of our streets thickens and daylight becomes twilight. If a slight wind shifts so as to fold over and double the coverlid of smoke, then at mid-day we have mid-night. Smoke not only loads fog with impurities but tends to produce fog. When, therefore, in the winter we happen upon a low temperature, a high barometer and a dead calm, we have an arctic night with a mephitic, irresponsible atmosphere in which we move about choking, our eyes irritated, our faces grimy—'a purblind race of miserable men.' It is then that our pulmonary mortality is run up, and the death-rate of the year determined."

In recent years, the researches of Prof. Leonard Hill deserve special attention. He has repeatedly drawn attention to the damage caused by smoke and fog in their obstruction of the antiseptic sunlight, and has pointed out that in London "for a period between Jan. 24th and Feb. 7th, 1880, the death-rate rose from 27 to 48, and in 1892, after a fortnight of fog, it rose to 42."

Fog as a Factor in Respiratory Death-rate in Glasgow.

In a paper read before the Sanitary Association of Scotland, Councillor Smith, of Glasgow, gave a very interesting account of the manner in which fog in the winter of 1909 increased the number of weekly deaths from respiratory disease in Glasgow. The effects were very well defined, as will be seen from Table I.

TABLE I.

Week ending—	No. of deaths.	Temperature.	Weather conditions.
Oct. weekly average	35	49·2	Clear to dull.
Nov. 6th	61	45·0	Three days fog.
„ 13th	75	44·0	Dull, slight fog.
„ 20th	138	39·7	Five days dense fog.
„ 27th	233	40·3	Hazy.
Dec. 4th	171	42·3	Hazy or wet.
„ 11th	198	37·0	Four days fog.
„ 18th	137	38·5	Slight haze.
„ 25th	95	31·9	Slight fog and clear.
Jan. 1st	93	43·1	Wet or clear.

It will be observed, however, that the statistics refer only to a particular year, and this limitation in the data must place a reservation on accepting the conclusions until the results of a series of years have

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXIV.—THE TREATMENT OF PSORIASIS.

UNFORTUNATELY the treatment of psoriasis is still in a very unsatisfactory position. Probably no great progress will be made till the cause of the disease is known. In many cases the eruption can be removed, if not permanently, at least for some years. In the bad cases, which relapse almost immediately after treatment is stopped, one can only hope to ameliorate the condition without curing it. The treatment may be either external or internal.

External Treatment.

This varies according as the eruption is spreading or stationary. If the eruption is spreading rapidly, is itchy, and shows numerous small recent spots, rest in bed is almost essential. If the patient goes about, the rubbing of the clothes and alterations in temperature tend to increase the spread. Rest in bed slows down the circulation and keeps the skin at an even temperature. All strong applications should be avoided. There is a great temptation to apply some strong ointment to check the eruption; but this never succeeds and simply leads to a further spread. The only way is to soothe the skin till the eruption stops spreading, and not till then is the actual cure begun. An ordinary warm bath should be given daily, and the scales washed off with plain soap and water. If the case is not too acute sulphur baths (potassa sulphurata ℥ii or a packet of sulphaqua to each bath) are often very beneficial. Night and morning plain vaseline or an ointment of 5 parts of soft paraffin and 1 part of hard paraffin should be rubbed in. After a week or ten days the eruption ceases to spread. The baths should be continued, but in place of the vaseline the following ointment should be used: ℞ sulph. præcip. and ac. salicyl aa gr. iiss, lanolin and vaseline aa ℥ss. This is continued as long as there is an improvement. As soon as the improvement ceases the sulphur and salicylic acid are increased to gr. 5 to ℥i (i.e., 1 per cent.), and later to gr. 10 to ℥i (2 per cent.). Finally crude coal tar, painted on very thinly with a stiff brush, should be applied to one area, and allowed to dry on and remain on for 24 hours. If no irritation is caused, the tar should be applied to all the other areas in rotation, doing the arms on the first day, the legs on the second, the front of the body on the third, and so on, taking about five days to paint all the spots. Each spot in this way gets tar for one day and the 2 per cent. sulphur salicylic ointment for the other four days. As the eruption becomes paler the tar should be painted on every fourth day, then every third day, every second day, and finally, when there are only a few spots left, every day. The patient should be kept in bed till the tar is found to be suiting the skin. In men, if the hair is cut short, the scalp can be tarred like the rest of the skin. The tar washes off easily if any grease such as the sulphur salicylic ointment is applied. Wood tars, such as ol. cadini, are not so efficacious as the crude coal tar, besides having the great disadvantage of the strong smell. Cases after treatment with crude coal tar, if thoroughly done, are much less liable to relapse than after any other form of local treatment. The course of treatment takes from eight to ten weeks to effect a cure.

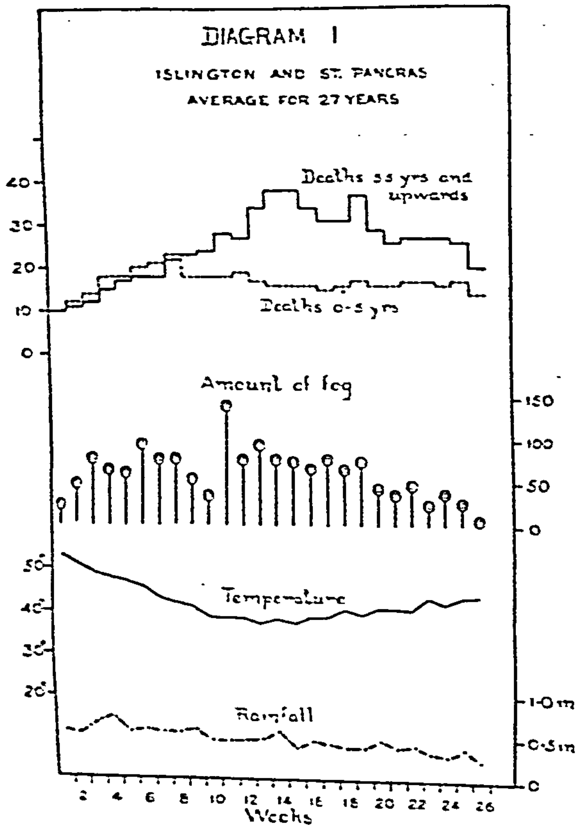
In cases where the psoriasis is extensive but no longer spreading the same treatment should be applied, beginning with the 1 per cent. sulph. salicylic ointment and going on rapidly to the stronger ointment and tar. Chrysarobin ointment is only useful in stationary cases, and should never be used if the eruption is itchy or spreading. It is not suitable for ambulatory cases. When it is used, it should be continued till the spots, which at first turn white, are beginning to show a pink colour again. After the chrysarobin treatment the case should be treated with crude coal tar to prevent recurrences. In many stubborn cases X rays will be found very useful. They should be applied once a fortnight in doses of one-half Sabouraud pastille at a distance of 15 cm. from the centre of the tube. With an ordinary gas tube the exposure is about seven to eight minutes. Usually two applications are sufficient to cause a marked improvement. The rays are especially useful when the eruption affects areas where it is difficult to get ointments into the lesions, such as on the palms and soles and the scalp. When applied to the scalp the dose is not sufficient to bring the hair out. It must be remembered, however, that the eruption does not stay away for any length of time after X rays. The ordinary local treatment must be applied at the same time. Whatever form of local treatment is applied it must be thorough. The scalp must be specially attended to as the disease is frequently left incompletely cured in that area. Unless every spot of disease is removed one cannot hope to prevent a recurrence.

Internal Treatment.

Drugs as a rule are rather unsatisfactory. Arsenic should be tried as Fowler's solution ♏ 5 t.i.d., but is only useful in stationary cases. Larger doses than ♏ 5 are useless, because if the arsenic is pushed till the patient is ill from it the psoriasis will improve temporarily, just as it does if the patient takes any acute illness such as pneumonia. As soon as the patient recovers from the arsenic the eruption recurs. The same remarks apply to thyroid extract. If a result cannot be obtained with small doses no permanent effect will be produced by large doses. The newer arsenical preparations of the arsenobenzol group have been tried, but the results obtained were disappointing. In spreading cases and also in chronic cases salicin gr. 10 t.i.d. is much more likely to do good than arsenic. Alkalies such as pot. citrat. gr. 15, together with mag. carb. gr. 5 t.i.d., are also sometimes useful. The reason for giving alkalies is based on the theory that in psoriasis the skin is too acid. From analogy with seborrhœic conditions, which are somewhat allied to psoriasis, there is some evidence that the skin is more acid than normal. The acne bacillus, which many believe to be identical with the seborrhœa bacillus, will only grow outside the body in an acid medium. Assuming that the skin is more acid than normal in psoriasis, that would explain why some individuals get psoriasis, and others, with less acid skins, do not. It is possible that in psoriasis there is a bowel infection with fermentation and the production of acid. Dieting should be tried in all cases. Psoriasis is certainly not due to any particular food, but good results may sometimes be obtained by cutting out or cutting down certain groups of foods, such as sugars, starches, meats, fats, and acid fruits. Each group should be cut down to the minimum in rotation. If an improvement is going to take place it will show itself within ten days or so. If this form of dieting produces no results, sending the patient to one of the spas, such as Harrogate, to get the bowel thoroughly cleared out does good in some cases. Drinking the waters alone is not usually sufficient; the lower bowel should be washed out by the Plombières douche. Vaccines made from the bowel contents have also been tried, but the results are usually disappointing.

Non-specific Protein Therapy.—In cases where all the above methods fail to give relief non-specific protein therapy may be tried. For this purpose sera, peptone, and sterilised milk have been chiefly used. Of the three, sterilised milk is the one to be recommended. If a foreign serum is used, such as horse serum, there is always the risk, although perhaps not a very great one, of anaphylactic shock reactions, and if the patient's own serum is used there is the difficulty of the technique which is and when these were omitted the coefficients became very small.

Effect of Low Temperature combined with Fog.



Having so far failed to trace any decided association between the prevalence of fog and an increased mortality from respiratory disease, it remained to investigate if fog required the conjunction of some other meteorological factor to produce an increase in the number of the weekly deaths. A graph (Diagram I.) was made of the average of the data in Table II., to which was added the average weekly amount of rain and the average weekly temperature prevailing throughout the 27 years. A reading of the diagram seemed to suggest that the conjoined effect of a low temperature and the prevalence of fog determined the increase in the deaths, particularly among adults. To test this point further, graphs were drawn for the individual years, and this characteristic was clearly confirmed. It was seen that in the same week with the advent of fog there was a large increase in the number of deaths, while at other times there was no material excess of mortality. An explanation of the phenomenon was afforded by the readings of the temperature curves. Whenever the prevalence of fog was associated with a depression in the temperature, then there was a rapid increase in the number of adult deaths, while in the absence of this decline no perceptible movement in the mortality curve took place. To illustrate this fact, Diagrams II., III., and IV. of the weekly deaths among children and adults, with the temperature, rainfall, and the amount of fog, are submitted for certain years. Diagram II. shows that there were three peaks in the mortality curves for the period October, 1874, to March, 1875, particularly defined in the case of the adults and, to a much less degree, in the case of the children, and that at each occurrence they were preceded by a low temperature and fog. On the other hand, in Diagram III., it will be clearly observed that the temperature between October, 1883, and March, 1884, was seldom below 40°, and that there was little oscillation in the number of deaths. The weather records for this winter contain the following details :—

1. Week Ending Nov. 3rd.

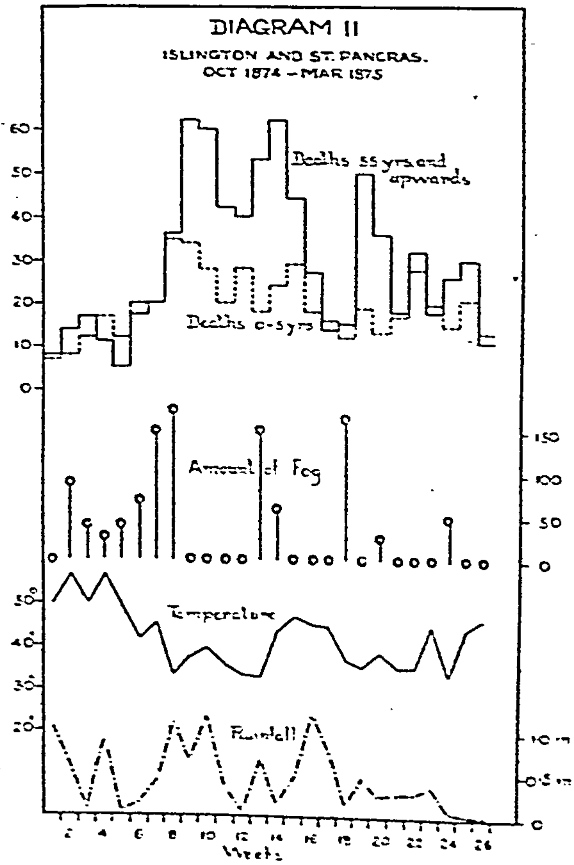
Explanatory Notes.

			9 A.M.		9 P.M.
Oct.	28th	.. Dense fog, 11 A.M.; fog in evening	ff.	..	Ov.
,,	29th	.. Foggy morning	Fog.	..	Fine.
,,	30th	.. Fair day, colder	,,	..	,,
,,	31st	.. Dull and cold	..	..	Ov.
Nov.	2nd	.. Foggy, dark morning	,,	..	,,

2. Week Ending Dec. 29th.

Dec.	24th	.. Fog in the morning	Fog.	..	Ov.
,,	25th	.. Foggy, dull, damp, and mild ..	,,	..	,,
,,	26th	.. Foggy, dull, but cooler	,,	..	,,
,,	27th	.. Fog all day	,,	..	Misty.
,,	29th	.. Overcast	,,	..	Ov.

ff. = very foggy. Ov. = overcast.



From these details it must be inferred that fog was fairly prevalent during the weeks in question, but, as will be seen from the diagram, it had a minimal effect on the deaths, any adverse influence it was likely to have being apparently counteracted by the high temperature prevailing. Diagram IV. is particularly interesting. Although the respiratory mortality after 1890 is largely associated with the prevalence of influenza, there was no epidemic of influenza from October, 1892, to March, 1893, as the weekly deaths in London as a whole were very low. Consequently, the respiratory deaths in this year may be safely regarded as non-influenzal. It will be observed from the diagram that there were two weeks characterised by a high prevalence of fog, one, the week ending Nov. 12th, and the other, the week ending Dec. 31st. The deaths among the children and adults were uninfluenced by the November fog, during which the temperature was over 44°, but after that in December, when the temperature fell to 27°, there was a rapid increase in the number of deaths among adults, with no corresponding excess among the children. As will be seen from the weather been analysed. Such is the object of the present paper.

Conditions of the Investigation.

For the purpose of the investigation, the area selected was that comprising the boroughs of Islington and St. Pancras, which contain in the aggregate a population of about 500,000 people. These districts are contiguous to Camden-square where the observations on fog were made, and they may also be regarded as experiencing the same weather conditions as the Regent's Park area, a good illustration of a fog-bound locality. The registers containing the fog and other weather records were deposited in the offices of the Royal Meteorological Society and access was kindly given to them. The records taken at 9 A.M. and 9 P.M. each day, together with the explanatory notes which described more fully the weather conditions prevailing throughout the day were abstracted from the registers for the six months, Oct. 1st to March 31st. It was deemed advisable to limit the investigation to the winter months as this is the period of the year when fog is usually prevalent. The records were extracted for a period of 30 years, but the data of only 27 years were utilised in the analysis owing to the fact that influenza became epidemic after 1890, and between that year and 1900 there were three outbursts—viz., 1892, 1894, and 1899. Accordingly, the excess number of respiratory deaths occurring in those years could not be differentiated from the complications arising out of the epidemics. For this reason these years were omitted. When the abstractions were completed the records were classified. Where it was stated that fog prevailed at 9 A.M. and at 9 P.M. and the explanatory notes indicated fog present throughout the day, the amount of fog for that particular day was represented by 100. Fog in the morning and lasting until noon was standardised as 50, due regard being given to the duration and intensity. A series of comparative figures of the daily amount of fog were thus obtained. The totals for the days were summed for each week and the sum taken as representing the amount of the fog during the week. These assessments can only be regarded as approximations, but they probably stand for a fair representation of the facts. The daily readings of temperature and rainfall were also taken out and reduced to weeks.

By the kindness of the Registrar-General, the registers containing the daily deaths occurring in the two boroughs for the period in question were placed at my disposal, and from them the respiratory deaths among children aged 0–5 years, and among adults aged 55 years and upwards, were extracted and tabulated in weeks. The analysis was confined to these periods of life as the mortality occurring at these ages embraces 70 per cent. of the total deaths from respiratory diseases. All deaths among children that could be regarded as complications of an infectious disease were excluded. A correction was then made for increase of population. This correction was most essential from a correlation standpoint, as otherwise, towards the end of the period under review, there would be a large number of weekly deaths as compared with those of the early years which would be due solely to the increased population from which they were derived, irrespective of any adverse influence fog may have had. The deaths for both children and adults were then written out in rows of 26 weeks—the period October to March—for the series of 27 years and summed. The totals revealed certain interesting features. The trend of the deaths among children is altogether different from that among adults. The graph of the former starts from a minimum in October and reaches its maximum in the last week of November, and then falls to what is practically a fixed level for the remaining weeks. On the other hand, the curve for adults, like that for the children, starts at a minimum but goes on increasing, with the exception of a very slight depression in the fourth week of December, and attains its maximum in the first or second week of January.

The Potency of Fog as a Factor in Increasing Respiratory Death-rate.

Having at my disposal the weekly amount of fog, the temperature, the rainfall, and the number of respiratory deaths both among children and adults, I was in a position to test the validity of the claim that fog is a potent factor in producing the increase in the respiratory death-rate. If fog has the alleged destructive effect, then, if no other disturbing factors existed, years containing many foggy days should show a large increase in the number of deaths as compared with those years when fog was less frequent. To test this point, the respiratory deaths among adults in each week from October to March and likewise the amount of fog were totalled for each of the 27 years. The correlation coefficient was then calculated for the amount of fog and the deaths at age 55 years and upwards for the series of 27 years and was found to be +0·441. This coefficient would appear to indicate that, as regards adults, there is an association between the amount of fog in any one year and the respiratory deaths, but, as will be shown later by diagrams, the coefficient is really evidence, not of a relationship between the amount of fog in any one year and the corresponding excess of deaths, but of the combined effect of fog and a low temperature on the respiratory death-rate.

The next point of interest to discuss was at what period of the winter fog produced its greatest effect on the respiratory deaths. For this purpose a table (Table II.) was made of the total deaths among children and adults and the amount of fog in each week of the year for the whole series of the 27 years. From this table it might be inferred that the maximum deaths among children was caused by the November fogs, and the increase among adults by the heavy fogs in December. To verify this, the correlation coefficients were calculated between (1) the amount of fog in the second week of November, the week of maximum fog in this month, and the number of deaths among children in the fourth week of November, the week of maximum deaths age 0–5, for the series of 27 years, and found to be −0·116, and (2) the amount of fog in the third week of December and the number of deaths among adults three weeks later, and found to be −0·066. The size and sign of these coefficients show that the period of maximum fog had no connexion with the causation of the maximum deaths.

Table II.—*Showing the Total Number of Deaths from Respiratory Disease among Children and Adults, with the Amount of Fog, in each Week from October to March for 27 Years, Beginning at 1870.*

Weeks.	Total deaths among—		Total amount of fog.	Weeks.	Total deaths among—		Total amount of fog.
	Children.	Adults.			Children.	Adults.	
1	264	270	630	14	433	1026	2130
2	331	301	1290	15	440	1033	1985
3	391	319	2050	16	427	920	1775
4	482	414	1700	17	407	845	2110
5	484	463	1610	18	424	849	1735
6	538	489	2580	19	456	1002	2005
7	572	481	2050	20	444	779	1143
8	613	604	2045	21	450	693	1005
9	492	619	1395	22	467	725	1285
10	493	647	925	23	471	727	610
11	480	749	3775	24	433	724	1030
12	508	720	2120	25	457	695	705
13	463	911	2535	26	372	527	180

It now remained to discover the general relationship between the amount of fog and the respiratory deaths in any one week. Accordingly, the amount of fog in each week of the year for the whole series of the 27 years was correlated with the respiratory deaths in the same week and in the subsequent week for both children and adults. In some cases fairly high correlation coefficients were obtained, but they were largely due to one or two observations in the series

Diagram III. and the first section of Diagram IV., where it is shown that although fog was rather prevalent there was no increase in the number of the deaths.

2. That if the prevalence of fog is associated with a low temperature and frost, the respiratory death-rate of adults can be influenced very considerably, although the effect is not evident in the case of children. This is illustrated by Diagram II. and the end of Diagram IV., and confirms the conclusions of the late Dr. Russell, of Glasgow, who maintained that "during winter every city was in danger of a catastrophe if certain weather conditions occurred, a combination of frost, fog, and still air for days together." It is also supported by the evidence of Table I., which Councillor Smith constructed for Glasgow.

NICKEL COOKING VESSELS.

ALTHOUGH pure nickel cooking vessels have not yet come into extended use, they have many obvious advantages. Pure nickel is very resistant to corrosion and takes a high polish which is readily retained. It is quite unattacked by soda, and even dilute hydrochloric and sulphuric acids have no appreciable action during a short time. These properties make it an easy matter to keep nickel cooking vessels scrupulously clean: grease may be removed with soda, and calcareous deposits from hard water may be removed by dilute hydrochloric acid. The crucial question, however, is whether foods cooked in nickel vessels can be contaminated with nickel in sufficient quantities to be in the least injurious when consumed regularly over prolonged periods. Nickel is usually regarded as one of the less toxic heavy metals such as iron and aluminium, rather than one of the more toxic group such as copper, lead, and mercury, and extensive investigations which have been made in foreign countries, notably Austria and Russia, have shown that this view is justified, and that no danger is likely to arise from the use of nickel cooking vessels.

Rohde[1] cooked fruits in nickel vessels, and could discover no ill-effects when these were eaten. These results were confirmed and amplified by Ludwig,[2] who cooked the food of a large household in nickel vessels for two and a half years and determined the amount of nickel in the different foods. The household consisted of nine or ten persons of ages 6–56, and none of them experienced the slightest ill-effects. The vessels used by Ludwig contained 98 per cent. of nickel, with traces of copper, iron, manganese, aluminium, and cobalt. A more elaborate investigation comprising pharmacological, chemical, and culinary experiments was published by Dzerzgowsky and Schumoff-Sieber in 1906.[3] Dogs were given daily doses of nickel sulphate equivalent to 5 to 10 mg. of metallic nickel per day for 200–220 days without any ill-effects being observed. At the end of the period, in which a total of 10–25 g. of metallic nickel had been given, no nickel was found in the organism, showing that no absorption takes place from the stomach and intestines. Repeated daily doses of as much as 0·5 g. of nickel sulphate were found to be harmless to a dog of 9 kg., corresponding to 0·70 g. of metallic nickel per day for a man of 70 kg. The foods cooked by them contained from 0·2 mg. nickel to 23 mg. per kg. in the case of very acid foods (Table I.), and this would introduce very much less than the above-mentioned tolerable amount. The amount of nickel dissolved by foods was found to be roughly proportional to the acidity and to the time of cooking. Elaborate tables are given showing the effects on nickel vessels of solutions of acetic, oxalic, butyric, lactic, and tartaric acids, both alone and in conjunction with common salt. Salt increases the amount of nickel dissolved by the organic acids. For example, 4 litres of 0·3 per cent. acetic acid boiled for three hours dissolved 0·0047 per cent. of nickel, and the same with the addition of 5 per cent. salt dissolved 0·0137 per cent. of nickel. If these were allowed to stand in the nickel saucepans for 11 hours after the three hours' boiling, the amounts of dissolved nickel were increased to 0·0203 per cent. and 0·0361 per cent. respectively. The area of nickel exposed to the acids in these experiments was 1209 square cm.

I., Ludwig; II., Lehmann; III., Dzerzgowsky and Schumoff-Sieber; IV., Normann and Hugel. v. s. tr. = very small trace.

Similar exhaustive experiments were subsequently published by Lehmann,[4] who also concluded that nickel cooking vessels were absolutely safe and hygienic. The same conclusion that nickel vessels were safe and suitable for cooking was reached by Normann and Hugel in 1913,[5] although these investigators found a rather higher proportion of nickel in most of the foods cooked by them. The quantities of nickel found by foreign investigators are summarised in Table I.

A search of the literature has failed to reveal any real evidence on the other side. The only case recorded where poisoning is attributed to metallic nickel in food or drink is one described by Faichnie and Langrish,[6] in which barley-water and lime-juice mixed stored in a large metal urn for a day produced sickness and vomiting. The urn was not of nickel, but of white metal coated with nickel, and although it is stated that analysis of the drink showed the presence of nickel, no quantity is mentioned, and no details are given. The poisoning may have been due to other metals such as copper. This occurrence took place in India during the hot season.

The degree of purity of the nickel vessels used by the previously quoted Continental investigators is not stated except by Ludwig, and the nickel cooking vessels made in this country are considerably purer than his. A specimen supplied to us, manufactured by Messrs. Joseph Sankey and Son, of Bilston, had the composition:—Nickel, 99·31 per cent.; iron, 0·44 per cent.; magnesium, 0·11 per cent.; carbon, 0·06 per cent.; copper, 0·05 per cent.; silicon, 0·03 per cent.; and experiments were made to see how the purer nickel behaved in comparison with that used by other investigators. In general, the results obtained with water, acetic acid, salt, &c., are similar to those of Dzerzgowsky and Schumoff-Sieber, but the records for the period, there was a greater amount of fog prevalent in the week ending Nov. 12th.

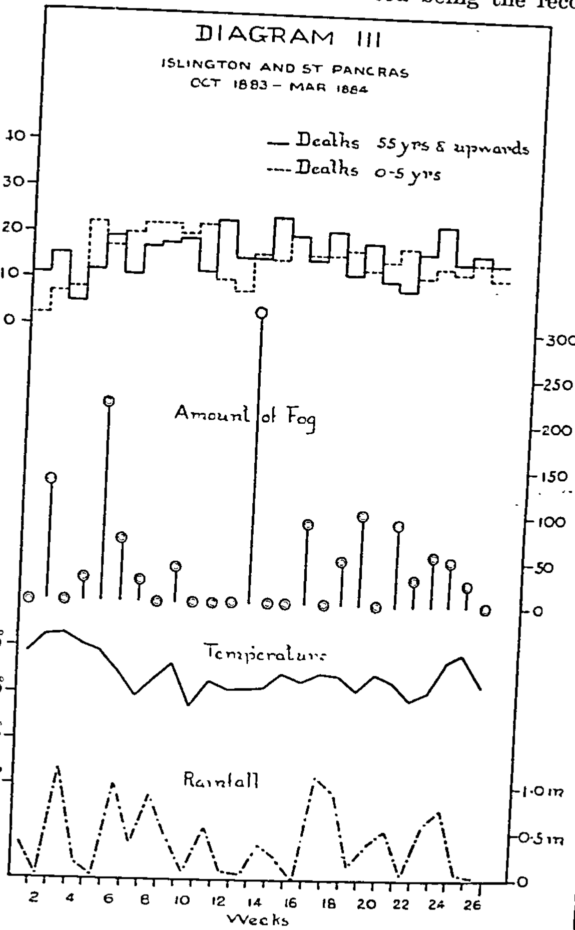
Week Ending Nov. 12th.

			9 A.M.		9 P.M.
Nov.	7th	.. Misty early, foggy towards evening and sunset	Fog.	..	Fog.
,,	8th	.. Fog more or less all day	,,	..	Ov.
,,	9th	.. Slight fog till 10 A.M.	Ov.	..	,,
,,	10th	.. Fog more or less all day, dense at times in the morning ..	Fog.	..	Fog.
,,	11th	.. Overcast throughout..	,,	..	Ov.
,,	12th	.. Clear at times, but very dark with high fog	Sl. fog.	..	,,

Week Ending Dec. 31st.

Dec.	27th	.. Rather dense fog in morning, clear after 1.30 P.M.	Fog.	..	Fine.
,,	28th	.. Fog all day; dense in morning and evening	,,	..	Fog.
,,	29th	.. Fog generally dense till 11.30, cleared suddenly, came on dense again at 1 P.M. ..	,,	..	Fair.
,,	30th	.. Fair, but slight fog in morning.	Sl. fog.	..	,,

To see if similar characteristics were present, the figures for London as a whole were graphed for the same year, the weather data used being the records



taken at Greenwich. The deaths in the case of the adults were from age 60 and upwards, as the weekly returns issued by the Registrar-General did not give the number at age 55. The two diagrams were identical—no excess of deaths after the fog in November when a high temperature prevailed, and a large excess among the adults in December following the low temperature and prevalence of fog. The Greenwich weather records are an interesting study for these weeks and are given in detail.

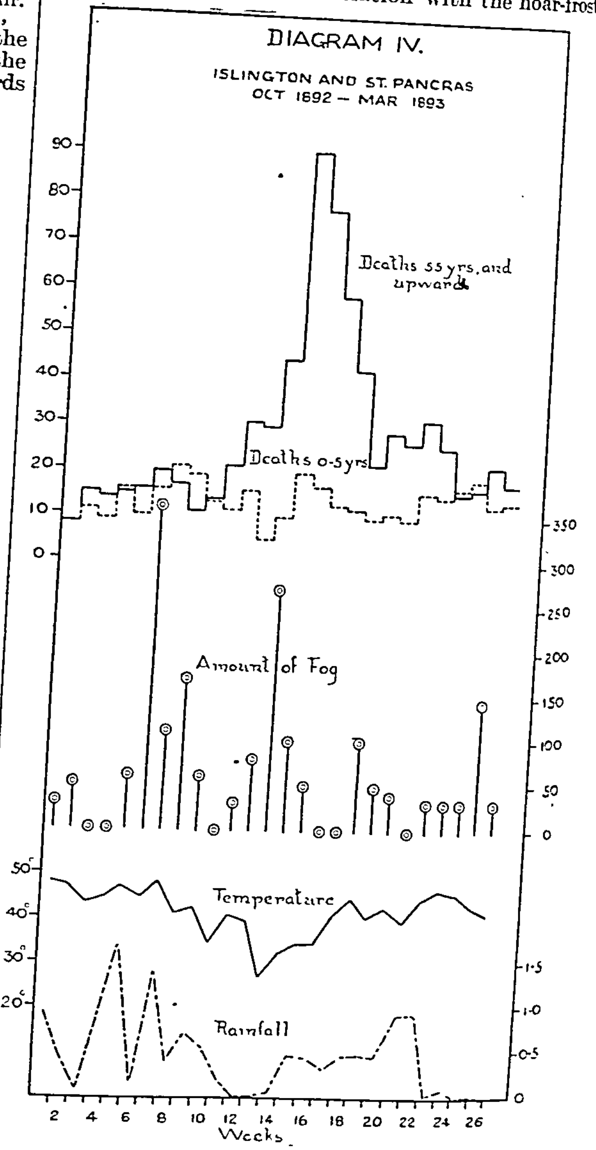
Week Ending Nov. 12th.

Nov. 7th .. Hoar-frost in the morning, generally cloudless, very foggy throughout the day.
,, 8th .. Dense fog throughout the morning.
,, 9th .. Overcast till evening, variable clouds, slightly foggy.
,, 10th .. Foggy in morning, overcast and foggy at night.
,, 11th .. Overcast, variable fog, occasional fine rain.
,, 12th .. Fog and rain in morning, fine for a short time in the afternoon.

Week Ending Dec. 31st.

Dec. 27th .. Variable clouds, fog and hoar frost, very cold day.
,, 28th .. Overcast, dense fog prevailed throughout, very cold.
,, 29th .. Fine, with variable amounts of cloud, slight fog in the morning and night; cold.
,, 30th .. Dense fog prevailed throughout the morning. Hoar-frost, very cold.

It is noteworthy that in the weather records for the week ending Dec. 31st there is frequent mention of the presence of hoar-frost. In February, 1880, when there was a great outburst of respiratory deaths both among adults and children in London as a whole, but confined to adults in the St. Pancras and Islington area, the prevalence of hoar-frost, low temperature, and fog are again mentioned in the Greenwich records. Whether the fog, in association with the hoar-frost, caused the increase in the number of deaths cannot be definitely determined. Much the more likely assumption is that the deciding influence was the conjoint effect of fog and low temperature and that the prevalence of hoar-frost was a mere indication of the decline in temperature.



Conclusions.

From the analysis of the present data there seems sufficient evidence to warrant the following conclusions:—

1. That fog itself has no appreciable effect on the respiratory death-rate, as will be observed from

Colonial List of the Medical Register, the Council had been informed that reciprocity would lapse on any refusal to register a class of practitioners whose names appeared on the Medical Register of the United Kingdom.

Colonel R. A. Needham, officially appointed to inspect Indian Universities and Colleges of Medicine, having been refused admission to the final examinations of Calcutta University, the University authorities had been informed that, in the absence of a report on these examinations, recognition by the G.M.C. of the medical degrees of that University would cease on Nov. 30th next.

In regard to the proposed Articles of Association of the Society of Radiographers, the Committee resolved to inform the Board of Trade of their strong objection to the last paragraph in Article 27 which proposed to entrust to an unqualified person the duty on his own responsibility of making and reporting a diagnosis of disease or injury to patients or others.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. A. A. Seeds retires on ret. pay.

Capts. to be Majs.: R. B. Price (Prov.), J. B. A. Wigmore (Prov.), J. Hare (Prov.), R. A. Flood (Prov.), E. C. Lang (Prov.), L. T. Poole (Prov.), C. C. Jones (Prov.), E. V. Whitby, E. U. Russell (Prov.), R. G. Shaw, N. T. Whitehead (and remains secd.), J. C. Sproule (Prov.), A. F. C. Martyn, G. F. Allison (Prov.), R. C. Carlyle (Prov.) (and remains secd.), A. A. M. Davies, Bt. Maj. L. Dunbar, and Bt. Maj. H. F. Panton (Prov.).

Capt. J. E. Brooks is restd. to the estabt.

Capt. J. W. Cannon retires receiving a gratuity.

Lt. M. A. Graham-Yooll is restd. to the estabt.

TERRITORIAL ARMY.

G. H. R. Gibson (late Canadian Army Med. Corps) to be Captain; W. M. Farr, J. J. Mitchell, I. Morgan, and F. A. Smorfitt to be Lts.; Hon. Lt. O. F. W. Robinson to be Lt.

DEATHS IN THE SERVICES.

We regret to announce the death of Colonel Reginald James Cope Cottell, C.B.E., R.A.M.C., on August 7th, after a prolonged illness borne with cheerful fortitude. The fourth son of Major James William Cottell, H.E.I.C.S., he was born at Rodborough, Gloucestershire, in October, 1858. He studied medicine at St. George's Hospital and obtained the Membership of the Royal College of Surgeons of England in 1886, having in the previous year become a Licentiate of the Society of Apothecaries. Immediately after qualifying he obtained a commission in the Royal Army Medical Corps and was subsequently stationed in Natal. He served throughout the South African War, 1899–1902, and received for his services the Queen's Medal and the King's Medal, both with three clasps. After serving in the Mediterranean he was appointed in 1906 assistant surgeon to the Royal Hospital, Chelsea, and some four years later physician and surgeon, positions which he held for three years. On the outbreak of the war he was put in charge of the recruiting stations in London and from 1915 to 1919 was commandant of King George's Hospital. In 1918 he was made a Knight of Grace of the Order of St. John of Jerusalem and in 1919 was awarded the C.B.E. (Military). He also received the rank of Brevet-Colonel. Colonel Cottell, who leaves a widow and three daughters, possessed a high sense of duty and was a very popular and competent officer.

GOVERNMENT publications on health matters are not yet as readily accessible at H.M. Stationery Office as they might be. Application for the Interim Report on Preservatives in Food, noticed in another column, was met by the statement that it was "not yet out." Application for Circular 1337 of the Board of Education dealing with the closure of schools during epidemics, and giving the consensus of medical opinion on this practice, was met by the rejoinder "not on sale." Application for the white paper on the Cost of Health Services, issued a week or two ago, elicited the statement that the document was "out of print." Whether too early, or too late, or ineligible, the inquirer may be prevented from satisfying laudable curiosity about matters of great moment to the health of the community. The attempt to purchase the publications was made on Tuesday morning, August 12th.

Medicine and the Law.

The Payment of Witness Fees to Medical Officers.

AT the last meeting before the summer recess the London County Council reached an important decision regarding the fees payable to medical officers of asylums, hospitals, and institutions for performing post-mortem examinations and giving evidence at coroners' inquests. Shortly expressed, the decision of the Council is to abolish payment altogether.

Section 22 of the Coroners Act, 1887, provides for payment of a fee of 2 guineas to private practitioners in this connexion. Under Subsection 2, however, no fee is payable when the deceased has died in a "county or other lunatic asylum, or in a public hospital, infirmary, or other medical institution," whether supported by endowments or by voluntary subscriptions. Notwithstanding this provision, fees have not been withheld from medical officers of workhouses and Poor-law institutions, but the attention of the L.C.C. has been directed to the question by a district auditor, who recently took exception to certain witness fees paid to medical officers of hospitals controlled by the Metropolitan Asylums Board. One such medical officer, on being asked to refund the fee, refused to do so, and the Public Control Committee took the view that it was "inequitable that a medical officer who happened to be employed in a certain type of publicly maintained institution should be receiving a fee, whereas another medical officer performing analogous duties and practically in a similar position should not be so paid." The Minister of Health was consulted by the Council, but declined to express any opinion on the matter. The district auditor on June 16th drew the Council's attention to the fact that, on the advice of eminent counsel, Poor-law union infirmaries had not hitherto been regarded as coming within the prohibition of the Act. He pointed out, however, that in recent years the character of these infirmaries had undergone a considerable change, and that in many instances they were in no way inferior to the best general hospitals. He had, therefore, decided that inquest fees were not payable to medical officers of "hospitals controlled by the Metropolitan Asylums Board, Poor-law infirmaries, general infirmaries, prisons, or other medical institutions of a public character." In his opinion such payments, if made, were illegal and an improper charge on the Council's funds. The London County Council has accepted this ruling and fixed Sept. 1st next as the date of discontinuance of the payments. The resolution passed by the Council was in the following terms:—

> "That, as from 1st September, 1924, the payment to medical officers of hospitals controlled by the Metropolitan Asylums Board, workhouses, Poor-law infirmaries, prisons, and other medical institutions of a public character, of fees under Section 22 of the Coroners Act, 1887, for making post-mortem examinations and giving evidence at inquests held in the County of London be discontinued."

The Home Secretary's Decision in Cases of Murder.

The Right Hon. Edward Shortt, who has had experience of the responsibility of the Home Secretary in granting or withholding reprieves, where murderers have been sentenced to death, contributed recently to the *Daily Express* an article recommending that the procedure should be altered and that the final decision on such occasions should rest with a committee. Probably the duty, which in the present circumstances the Home Secretary performs alone, is one of which most men would gladly be relieved, and the suggestion that a committee should undertake it is not a new one, and is quite likely some day to be considered by Parliament. Mr. Shortt, however, has made a definite proposal that the committee should be composed of the foods cooked showed less nickel dissolved in them than in the case of the continental experiments. Results are summarised in Table II., and it will be seen that the quantities of nickel found are quite without significance, even in the case of such an acid food as rhubarb. Onions were cooked to see whether the large proportion of sulphur contained in them caused any blackening through the formation of nickel sulphide. The onions themselves were not stained at all, but the saucepan showed a slight brown discoloration of nickel sulphide, which was easily removed.

TABLE II.—*British Pure Nickel Cooking Vessels.*

Material boiled or cooked in the nickel vessel.	Time of boiling in hours.	Mg. nickel per kg. of material.	Mg. nickel dissolved per sq. decimetre of surface.
Decinormal sodium carbonate	1	0	0
London tap water	2	0	0
Distilled water	1	0·2	0·03
0·8 per cent. NaCl	1	0·9	0·23
0·1 per cent. acetic acid with 2 per cent. NaCl	1½	21·0	5·94
0·3 per cent. acetic acid with 0·8 per cent. NaCl ..	1	22·4	4·68
1 per cent. citric acid ..	1	45·0	9·4
4 per cent. acetic acid ..	1	260·0	54·1
Rhubarb	¾	4·0	0·60
Stewed lamb	1½*	v. sl. tr.	—
Boiled broad beans	½	0	0
Potatoes fried in lard ..	—	0	0
Lard fried alone	—	0	0

* Left in nickel saucepan overnight. v. sl. tr.—Very slight trace.

These pure nickel vessels are therefore eminently suitable from the point of view of metallic contamination of the food, and quite equal to those made of aluminium in this respect. They are superior to aluminium with regard to cleanliness. They remain quite bright if left filled with water for several days, whereas aluminium is liable to become partially coated with spongy oxide. Calcareous deposits may be removed by dilute hydrochloric acid, without any nickel being dissolved. This was proved by etching some of the nickel with nitric acid and then soaking it for a quarter of an hour in 2 × normal hydrochloric acid, when no trace of nickel could be found in solution. Pure nickel therefore appears to be the ideal material for cooking vessels from the hygienic point of view, its only drawback being its high first cost, though this may be offset by its extreme durability, in which respect it is probably far superior to any other material used for this purpose.

Similar nickel utensils to the sample experimented with are manufactured by Messrs. Joseph Sankey and Sons from sheets made of pure Mond nickel, guaranteed over 99 per cent., and are produced by Henry Wiggin and Co., Ltd., 55. George-street Parade, Birmingham.

INTERNATIONAL DENTAL FEDERATION.

A MEETING of the International Dental Federation was held in the city of Luxemburg on August 3rd, 4th, and 5th, and was attended by delegates from numerous dental associations in various parts of the world. The proceedings opened in the town hall under the presidency of the Minister of Education, Director-General Herr Nevens, who welcomed the delegates to Luxemburg and wished them a most successful conference. Among the delegates who spoke were: Mr. Blatter (Paris), Herr Schäeffer-Stuckert (Frankfort-on-Main), Dr. G. Bandoux (Brussels), Dr. G. Griepeschock (Riga), Dr. Friesell (Pittsburgh, U.S.A.), and Mr. W. B. Paterson (London).

Mr. Paterson remarked upon the reappearance of a spirit of fraternity exhibited in the speeches of the delegates. He believed that it was the first time since the war that such an amicable disposition had been shown in any meeting, whether dental or medical.

Dr. Truman W. Brophy (Chicago), President of the Federation, thanked the Minister and the other speakers, and desired that a message expressive of the grateful thanks of the meeting might be conveyed to the Grand Duchess of Luxemburg for her patronage. The programme of the meeting was afterwards discussed in detail in the various commissions appointed.

The Hygiene Commission reported the general and increasing prevalence of dental caries throughout the civilised countries of the world. All the delegates present were unanimous upon that point.

Upon that report the Federation advised the desirability of establishing a dental department under a dental controller in the Ministries of Health of all countries. Only two or three countries had adopted this course so far.

The Commission on Documentation reported that it had established at the Palais Mondial, Brussels, a catalogue of all the important works and papers on dental subjects, extending back for a period of over 17 years. Copies or references could be obtained for a nominal sum by letter addressed to the director.

The relief fund for Russian dentists had been distributed in 1923 by Dr. Florestan Aguilar (Madrid) on behalf of the International Dental Federation. Leningrad (Petrograd), Moscow, and Odessa had been visited for that purpose, and 260 complete outfits of dental instruments had been distributed. Dr. Griepeschock (Riga), who had been imprisoned by the Bolsheviks, described the gratitude shown by Russian dentists for these valuable gifts.

Questions relating to the organisation of the next or seventh International Dental Congress, at which a membership of over 8000 members was expected, were brought forward by Dr. King (Chicago), the general secretary of the Congress, and were replied to by Dr. W. Guy (Edinburgh), Prof. W. H. Gilmour (Liverpool), and Dr. Georges Villain (Paris).

The award of the Miller Memorial Prize for important work in connexion with dentistry was made to Dr. Brophy, dean of the Chicago Dental School, Mr. J. Howard Mummery (London) announced the result of the ballot for the prize, and congratulated the recipient.

The next meeting of the International Dental Federation was fixed to take place in Geneva on August 5th and two following days in 1925 at the invitation of the Swiss National Dental Association.

GENERAL MEDICAL COUNCIL.

MEETING OF EXECUTIVE COMMITTEE, JULY 28TH.

THE Committee was officially notified of the re-appointment of Dr. David Hepburn as representative of the University of Wales for one year from July 16th, 1924, and of Dr. Arthur Thomson as representative of the University of Oxford for five years from June 21st, 1924.

Notice was taken of the restoration to the Medical Register—the prescribed conditions having been duly fulfilled—of the following names erased in conformity with Section XIV. of the Medical Act, 1858:—

Dawson, Thomas (S.)
Harmar, Mary (S.)
Hill, Arthur R. (S.)
Hillier, Sidney (S.)
Orr, Andrew W. (I.)
Raitt, Oswald (S.)
Russell, Wilfred A.
Thompson, Thomas R. S. (I.)
Tough, James B. K. (S.)
Woo, Arthur W.

the names with the bracketed affixes (S.) and (I.) having been sent for restoration by the Scottish and Irish Branch Registrars respectively.

Sir Nestor Tirard was appointed to attend a conference at the Ministry of Health of representatives of Departments and bodies concerned, in anticipation of the International Conference for the Unification of Drastic Drugs to be held in 1925 at Brussels.

In regard to the refusal of the Council of Physicians and Surgeons of New Brunswick to register in that province an applicant whose name appeared upon the

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

(*Continued from p. 296.*)

SECTION OF SURGERY.

WEDNESDAY, JULY 23RD.

ON the first day, Sir CUTHBERT WALLACE, the President, being in the chair, a discussion on

Acute Osteomyelitis

was opened by Mr. JOHN FRASER (Edinburgh). He began by pointing out the confusion which exists as to anatomical terms in relation to the structure of the bones, and defined the metaphysis as that portion of the diaphysis which lies adjacent to the epiphyseal cartilage. He said: The metaphysis is the site during the years of growth of the most intense cell activity and is the most vascular area of the bone. It is the site of origin of most of the inflammatory diseases of the bones, and in particular of acute osteomyelitis. This is essentially an infective process in the interior of the bone, the endosteum and the marrow being first affected. It is only at a later stage that the infection spreads through the bone and involves the periosteum. A primary periostitis is extremely rare. Acute osteomyelitis is then the result of an acute pyogenic infection of the metaphysis, and it is essentially an affection of the age of growth. In the vast majority of cases the infection is blood-borne, and this presupposes a mild form of septicæmia. That such a septicæmia occurs, and indeed is common in young children, the recent work of Lipschitz shows. The source may be any septic focus, in the teeth, tonsils, sinuses, or skin for example, or pneumonia and the exanthemata. An important source is the umbilicus, and Mr. Fraser referred to a series of 30 cases in young infants which he had collected in the last four years, all of them fatal. In his opinion umbilical infection is a common origin of obscure blood infection in infancy, the infection sometimes persisting until the years of later childhood. The disease tends to be localised in certain special sites, and in order of frequency these are the upper end of the tibia, the lower end of the femur, the lower end of the tibia, and the upper end of the humerus. Slight trauma is probably an important factor in causation, and this would explain the high proportion of cases in boys and in the lower limbs, but the trauma must be slight, probably resulting only in a small metaphyseal hæmorrhage. The large metaphyseal surfaces seem to be more readily affected than the small. Boys are affected more often than girls in the proportion of 6 to 1, and the eighth to the twelfth year is the period in which the disease is most common. In a series of 400 cases the responsible organism was the *Staphylococcus aureus* in 78 per cent., the pneumococcus in 11 per cent., and the streptococcus in 6 per cent. The number of cases of pneumococcal infection was an important point to be discussed later.

The disease starts in the metaphysis with an intense primary infection of the medulla. The inflammatory products are under extreme tension, and this accounts for the intensity of the local symptoms and the severity of the toxæmia which results. From the point of view of prognosis this is the most dangerous stage, for it is now that septicæmia in an acute form is most likely to occur. The second stage is evidenced by a spread of the infection from the interior of the bone into the subperiosteal area. The vessels and spaces of the Haversian canals are the routes along which the migration occurs, and a serous subperiosteal effusion is followed by a purulent one. With the relief of tension the symptoms abate and the prognosis improves. The facility with which the second stage can be established will depend on the number of the Haversian canals and the porosity of the bone, and the density of the femur may account for the severity of the symptoms associated with infections of this bone. The greater porosity of the tibia and the humerus makes it easier for the products of inflammation to escape from the interior of the bone. The third stage is that of reaction. The osteoblasts in the deeper layers of the periosteum proliferate, an involucrum is laid down, and the dead portion of the diaphysis is separated by the active phagocytic action of the granulation tissue which is formed.

The *clinical features* are intense and distinctive. There is the agonising pain of the early stage while the infection is still locked up under tension in the interior of the bone. It is during this stage that the signs of toxæmia—the high temperature, the delirium, the poisoned appearance—are greatest. It is at this stage that a massive invasion of the blood-stream may inaugurate a septicæmia which by its intensity overshadows the local signs. With the relief of tension which characterises the stage of subperiosteal effusion there is an immediate abatement of signs and symptoms, the pain diminishes, the temperature falls, the general appearance improves. But there is an element of danger in this stage because the sudden relief of symptoms may raise doubts as to the veracity of the diagnosis. Unless the condition is relieved by treatment the signs and symptoms are re-established as the tension again rises, and the features are now those of a local septic infection.

The *diagnosis* is usually established without much difficulty from the intensity of the local symptoms and the evidences of severe toxic absorption. In some cases the depth of the lesion may lead to difficulty. Thus osteomyelitis of the ilium may be mistaken for appendicitis or infection of the hip-joint. A blood count should avoid confusion with acute rheumatism, and cellulitis should be excluded by the less intense toxæmia by which it is usually accompanied. As regards prognosis, the more distal the lesion and the more porous the bone the better is the outlook. The real danger lies in the septicæmia which may develop in the first stage of the disease. The tendency to this is perhaps greater in young children.

The speaker was of opinion that in a certain class of case operation was neither necessary nor desirable. These were the cases described by pathologists as albuminous or serous *osteomyelitis*, a large proportion of which were produced by pneumococcal infection. In these cases operation in the early stages was likely to result in spreading the infection and in the production of necrosis. They usually occur in babies and young children, the temperature is rarely as high as in the ordinary suppurative osteomyelitis, the toxæmia is slight, and the neighbouring joint is usually the site of a serous effusion. A blood count shows that there is only a small degree of *leucocytosis*. In these cases operation should be delayed, and extension applied to the limb, with fixation splints and hot local applications. Under this treatment a large number of the cases will resolve, and even if suppuration ensues it is local in its extent. It is to be suspected if the temperature rises after a preliminary fall, if pain persists, or if local redness or œdema appear. Relief may be obtained by a single trephine opening over the focus of suppuration. In the ordinary cases, however, immediate operation is essential in order to cut short the grave risks of the first stage. A trephine opening is first made over the affected metaphysis, and this is followed by a series of openings along the shaft at intervals of three-quarters of an inch until healthy marrow is reached. The intervening bone is now cut away with a chisel, so as to fully expose the infected area, but the marrow is not touched at all, as scraping it only disseminates the infection and leads to necrosis of the bone. The wound is left widely open and Carrel-Dakin treatment is established. In three weeks it may be possible to close the wound partially by secondary suture. The speaker had tried the method of subperiosteal resection of the affected portion of the diaphysis, but has abandoned it except in those cases where the whole of the diaphysis has perished. He considered that it was likely to dissemi-

Home Secretary, the Lord Chief Justice, and the judge who tried the convicted person. This seems a combination open to objections, particularly with regard to the judge who tried the case. Moreover, if such a committee is ever instituted it should include a member of the medical profession of recognised eminence. He would not necessarily, or desirably, be an alienist or one connected with any special branch of medicine. Prisoners are reprieved upon medical grounds of varying nature. For example, True was reprieved on the ground of his mental condition; Mrs. Maybrick and others have been sentenced and not executed on account of questions relating to the precise cause of the death of the person alleged to have been murdered. If such a committee as that suggested should ever be formed, there would certainly be many occasions upon which a medical man would materially assist his colleagues in the weighing of medical evidence.

Coroners and Murder or Manslaughter.

Sir Harry Poland, in a letter to the *Times*, has made a suggestion that when an inquest is being held by a coroner and a prosecution takes place at the same time in a criminal court for murder or manslaughter, the same death forming the subject of the prosecution and of the inquest, the inquest should be suspended until the criminal proceedings have been concluded. A proposal coming from so eminent an authority on the practical working of the criminal law commands respect, and no doubt full consideration will be given to Sir Harry Poland's suggestion whenever (or if ever) the long-delayed amendment of the law relating to inquests takes place. He cites the report of a Royal Commission in 1879, which said that "the proceeding upon coroner's inquisitions is a relic of the times preceding the appointment of justices of the peace." His strongest argument against the dual proceedings, in the coroner's court and before magistrates, which precede trial at assizes, is that the time of witnesses is taken up unnecessarily. Medical practitioners who have had to give evidence on such occasions will be aware how many valuable hours are wasted in waiting about on these occasions, in addition to the possibly brief period of time which is spent in the witness-box. The time of experts is no less wasted in repeating the same evidence which again has to be given later. All these should be thoroughly in sympathy with the proposed alteration, and it will be interesting to see what legal critics may have to say on the subject. They are aware of the anomalies attaching to inquest verdicts and proceedings. In the recent case of Vaquier the coroner's jury found a verdict which left open the question of who had placed the poison in the bottle from which the dead man took the fatal draught, and this was employed as an argument by some of those persons who advocated the Frenchman's reprieve. That it has had no effect on Vaquier's ultimate fate tends to show that the verdict at an inquest is of little value. At the inquest upon Miss Kaye letters were read from the deceased to her friends which could not have been made evidence at Mahon's trial, which suggests that an inquest may prejudice a prisoner when tried for his life, owing to the publication of matter not relevant to his guilt. In fact, in the case of Mahon a letter of similar character to those read at the inquest led to newspapers which published it being fined for "contempt of court." The gravity of the penalty attaching to murder may be urged as an argument for retaining the triple hearing, but it seems doubtful whether that is a reason of such weight that it ought to prevail. The fact of coroners not being responsible for inquiries in obvious cases of murder would do away with any argument against the appointment of medical men in preference to lawyers, and the medical man of experience would show himself the best person to inquire into all unexplained deaths, including those which through his investigation may turn out to have been due to criminal acts. Sir Harry Poland's suggestion has much to commend it.

A Secret Well Kept.

In a case committed for trial at Rotherham, the prisoner being charged with concealment of birth after the finding of the dismembered body of an infant, observations were made by counsel upon the conduct of a medical man, Dr. W. L. Dibb, and of a deputy coroner, to the effect that they had not assisted the police in elucidating the case. Dr. Dibb, in particular, had given no information to the police as to what he knew or suspected with regard to the remains which had been submitted to him. In explanation of this, at the close of his evidence before the magistrates, Dr. Dibb made a statement to the effect that, finding himself in the possession of certain information, he had consulted a solicitor as to the course he should adopt, and the solicitor had expressed a wish to take counsel's opinion before expressing himself definitely. The witness had also consulted a senior practitioner at Rotherham and a consultant at Sheffield, who had agreed that he ought not to make a statement to the police. In the witness-box Dr. Dibb had given evidence, after having heard authorities cited by counsel, which were to the effect that he could not refuse to do so. He appears to have acted perfectly correctly, both in giving evidence when in the witness-box and when the court refused to absolve him from the obligation to give it, and in not going out of his way to make statements to the police before. He also acted wisely in taking advice on the subject from those best qualified to assist him and in acting on their recommendations. The kind of circumstances, in which he evidently found himself involved, are such as may occur in the practice of any medical man. A doctor is not at law absolved owing to his profession from the ordinary duties of a citizen to assist in the administration of justice if called upon to do so. No medical man, however, will admit that because his profession brings him in contact with what may be a "guilty secret," his duty as a citizen calls upon him to play the detective and assist the police in any and every case in which he suspects the past or future perpetration of a criminal act by his patient. He must be guided to some extent by the facts of the particular case, and it may be suggested as an example that if he has reason to believe that the life of a human being is threatened, or that murder has been committed, he is placed in a very different position from that of merely suspecting that a patient may have been connected with an offence against property.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 2ND, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 36; scarlet fever, 1330; diphtheria, 663; enteric fever, 94; pneumonia, 458; puerperal fever, 37: cerebro-spinal fever, 2; acute poliomyelitis, 27; acute polio-encephalitis, 4; encephalitis lethargica, 68; dysentery, 6; ophthalmia neonatorum, 108. Of the cases of ophthalmia 12 were reported from the County of London, 3 from West Hartlepool, 2 from Easington R.D. (co. Durham), 5 from Liverpool, 4 from Newcastle-on-Tyne, 4 from Stoke-on-Trent, 12 from Birmingham, 7 from Sheffield; 6 from the boroughs and urban districts of Glamorgan—namely, Aberdare, Caerphilly, Ogmore and Garw, Port Talbot (each 1), and Rhondda (2).

Deaths.—In the aggregate of great towns (including London) there were 6 deaths from enteric fever, 9 from scarlet fever, 21 from diphtheria, 22 from measles, and 15 from influenza. In London itself the diphtheria deaths numbered 8.

THE LATE DR. R. T. JONES.—Dr Richard Thomas Jones, L.R.F.P.S. Glasg. and L.S.A. Lond, who recently died at his residence in Harlech, Merionethshire, began to practise in 1879. He received his medical education at Owens College, Manchester, and at Guy's Hospital, London, and settled in Wales, where he worked for 45 years. He was one of the first medical men in the Principality to advocate total abstinence on which subject he wrote several pamphlets. He was medical officer and public vaccinator for the Llanfihangel district of the Festiniog Union. For over 30 years he was district magistrate and was also High Sheriff of Merioneth.

ANNUAL MEETING AT BRADFORD.

(Continued from p. 288.)

SECTION OF SURGERY.

WEDNESDAY, JULY 23RD.

ON the first day, SIR CUTHBERT WALLACE, the President, being in the chair, a discussion on

Acute Osteomyelitis

was opened by MR. JOHN FRASER (Edinburgh). He began by pointing out the confusion which exists as to anatomical terms in relation to the structure of the bones, and defined the metaphysis as that portion of the diaphysis which lies adjacent to the epiphyseal cartilage. He said: The metaphysis is the site during the years of growth of the most intense cell activity and is the most vascular area of the bone. It is the site of origin of most of the inflammatory diseases of the bones, and in particular of acute osteomyelitis. This is essentially an infective process in the interior of the bone, the endosteum and the marrow being first affected. It is only at a later stage that the infection spreads through the bone and involves the periosteum. A primary periostitis is extremely rare. Acute osteomyelitis is then the result of an acute pyogenic infection of the metaphysis, and it is essentially an affection of the age of growth. In the vast majority of cases the infection is blood-borne, and this presupposes a mild form of septicæmia. That such a septicæmia occurs, and indeed is common in young children, the recent work of Lipschitz shows. The source may be any septic focus, in the teeth, tonsils, sinuses, or skin for example, or pneumonia and the exanthemata. An important source is the umbilicus, and Mr. Fraser referred to a series of 30 cases in young infants which he had collected in the last four years, all of them fatal. In his opinion umbilical infection is a common origin of obscure blood infection in infancy, the infection sometimes persisting until the years of later childhood. The disease tends to be localised in certain special sites, and in order of frequency these are the upper end of the tibia, the lower end of the femur, the lower end of the tibia, and the upper end of the humerus. Slight trauma is probably an important factor in causation, and this would explain the high proportion of cases in boys and in the lower limbs, but the trauma must be slight, probably resulting only in a small metaphyseal hæmorrhage. The large metaphyseal surfaces seem to be more readily affected than the small. Boys are affected more often than girls in the proportion of 6 to 1, and the eighth to the twelfth year is the period in which the disease is most common. In a series of 400 cases the responsible organism was the *Staphylococcus aureus* in 78 per cent., the pneumococcus in 14 per cent., and the streptococcus in 6 per cent. The number of cases of pneumococcal infection was an important point to be discussed later.

The disease starts in the metaphysis with an intense primary infection of the medulla. The inflammatory products are under extreme tension, and this accounts for the intensity of the local symptoms and the severity of the toxæmia which results. From the point of view of prognosis this is the most dangerous stage, for it is now that septicæmia in an acute form is most likely to occur. The second stage is evidenced by a spread of the infection from the interior of the bone into the subperiosteal area. The vessels and spaces of the Haversian canals are the routes along which the migration occurs, and a serous subperiosteal effusion is followed by a purulent one. With the relief of tension the symptoms abate and the prognosis improves. The facility with which the second stage can be established will depend on the number of the Haversian canals and the porosity of the bone, and the density of the femur may account for the severity of the symptoms associated with infections of this bone. The greater porosity of the tibia and the humerus makes it easier for the products of inflammation to escape from the interior of the bone. The third stage is that of reaction. The osteoblasts in the deeper layers of the periosteum proliferate, an involucrum is laid down, and the dead portion of the diaphysis is separated by the active phagocytic action of the granulation tissue which is formed.

The *clinical features* are intense and distinctive. There is the agonising pain of the early stage while the infection is still locked up under tension in the interior of the bone. It is during this stage that the signs of toxæmia—the high temperature, the delirium, the poisoned appearance—are greatest. It is at this stage that a massive invasion of the blood-stream may inaugurate a septicæmia which by its intensity overshadows the local signs. With the relief of tension which characterises the stage of subperiosteal effusion there is an immediate abatement of signs and symptoms, the pain diminishes, the temperature falls, the general appearance improves. But there is an element of danger in this stage because the sudden relief of symptoms may raise doubts as to the veracity of the diagnosis. Unless the condition is relieved by treatment the signs and symptoms are re-established as the tension again rises, and the features are now those of a local septic infection.

The *diagnosis* is usually established without much difficulty from the intensity of the local symptoms and the evidences of severe toxic absorption. In some cases the depth of the lesion may lead to difficulty. Thus osteomyelitis of the ilium may be mistaken for appendicitis or infection of the hip-joint. A blood count should avoid confusion with acute rheumatism, and cellulitis should be excluded by the less intense toxæmia by which it is usually accompanied. As regards prognosis, the more distal the lesion and the more porous the bone the better is the outlook. The real danger lies in the septicæmia which may develop in the first stage of the disease. The tendency to this is perhaps greater in young children.

The speaker was of opinion that in a certain class of case operation was neither necessary nor desirable. These were the cases described by pathologists as albuminous or serous osteomyelitis, a large proportion of which were produced by pneumococcal infection. In these cases operation in the early stages was likely to result in spreading the infection and in the production of necrosis. They usually occur in babies and young children, the temperature is rarely as high as in the ordinary suppurative osteomyelitis, the toxæmia is slight, and the neighbouring joint is usually the site of a serous effusion. A blood count shows that there is only a small degree of leucocytosis. In these cases operation should be delayed, and extension applied to the limb, with fixation splints and hot local applications. Coroners and Murder or Manslaughter.

Sir Harry Poland, in a letter to the *Times*, has made a suggestion that when an inquest is being held by a coroner and a prosecution takes place at the same time in a criminal court for murder or manslaughter, the same death forming the subject of the prosecution and of the inquest, the inquest should be suspended until the criminal proceedings have been concluded. A proposal coming from so eminent an authority on the practical working of the criminal law commands respect, and no doubt full consideration will be given to Sir Harry Poland's suggestion whenever (or if ever) the long-delayed amendment of the law relating to inquests takes place. He cites the report of a Royal Commission in 1879, which said that "the proceeding upon coroner's inquisitions is a relic of the times preceding the appointment of justices of the peace." His strongest argument against the dual proceedings, in the coroner's court and before magistrates, which precede trial at assizes, is that the time of witnesses is taken up unnecessarily. Medical practitioners who have had to give evidence on such occasions will be aware how many valuable hours are wasted in waiting about on these occasions, in addition to the possibly brief period of time which is spent in the witness-box. The time of experts is no less wasted in repeating the same evidence which again has to be given later. All these should be thoroughly in sympathy with the proposed alteration, and it will be interesting to see what legal critics may have to say on the subject. They are aware of the anomalies attaching to inquest verdicts and proceedings. In the recent case of Vaquier the coroner's jury found a verdict which left open the question of who had placed the poison in the bottle from which the dead man took the fatal draught, and this was employed as an argument by some of those persons who advocated the Frenchman's reprieve. That it has had no effect on Vaquier's ultimate fate tends to show that the verdict at an inquest is of little value. At the inquest upon Miss Kaye letters were read from the deceased to her friends which could not have been made evidence at Mahon's trial, which suggests that an inquest may prejudice a prisoner when tried for his life, owing to the publication of matter not relevant to his guilt. In fact, in the case of Mahon a letter of similar character to those read at the inquest led to newspapers which published it being fined for "contempt of court." The gravity of the penalty attaching to murder may be urged as an argument for retaining the triple hearing, but it seems doubtful whether that is a reason of such weight that it ought to prevail. The fact of coroners not being responsible for inquiries in obvious cases of murder would do away with any argument against the appointment of medical men in preference to lawyers, and the medical man of experience would show himself the best person to inquire into all unexplained deaths, including those which through his investigation may turn out to have been due to criminal acts. Sir Harry Poland's suggestion has much to commend it.

A Secret Well Kept.

In a case committed for trial at Rotherham, the prisoner being charged with concealment of birth after the finding of the dismembered body of an infant, observations were made by counsel upon the conduct of a medical man, Dr. W. L. Dibb, and of a deputy coroner, to the effect that they had not assisted the police in elucidating the case. Dr. Dibb, in particular, had given no information to the police as to what he knew or suspected with regard to the remains which had been submitted to him. In explanation of this, at the close of his evidence before the magistrates, Dr. Dibb made a statement to the effect that, finding himself in the possession of certain information, he had consulted a solicitor as to the course he should adopt, and the solicitor had expressed a wish to take counsel's opinion before expressing himself definitely. The witness had also consulted a senior practitioner at Rotherham and a consultant at Sheffield, who had agreed that he ought not to make a statement to the police. In the witness-box Dr. Dibb had given evidence, after having heard authorities cited by counsel, which were to the effect that he could not refuse to do so. He appears to have acted perfectly correctly, both in giving evidence when in the witness-box and when the court refused to absolve him from the obligation to give it, and in not going out of his way to make statements to the police before. He also acted wisely in taking advice on the subject from those best qualified to assist him and in acting on their recommendations. The kind of circumstances, in which he evidently found himself involved, are such as may occur in the practice of any medical man. A doctor is not at law absolved owing to his profession from the ordinary duties of a citizen to assist in the administration of justice if called upon to do so. No medical man, however, will admit that because his profession brings him in contact with what may be a "guilty secret," his duty as a citizen calls upon him to play the detective and assist the police in any and every case in which he suspects the past or future perpetration of a criminal act by his patient. He must be guided to some extent by the facts of the particular case, and it may be suggested as an example that if he has reason to believe that the life of a human being is threatened, or that murder has been committed, he is placed in a very different position from that of merely suspecting that a patient may have been connected with an offence against property.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 2ND, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 30; scarlet fever, 1330; diphtheria, 663; enteric fever, 94; pneumonia, 458; puerperal fever, 37; cerebro-spinal fever, 2; acute poliomyelitis, 27; acute polio-encephalitis, 4; encephalitis lethargica, 68; dysentery, 6; ophthalmia neonatorum, 108. Of the cases of ophthalmia 12 were reported from the County of London, 3 from West Hartlepool, 2 from Easington R.D. (co. Durham), 5 from Liverpool, 4 from Newcastle-on-Tyne, 4 from Stoke-on-Trent, 12 from Birmingham, 7 from Sheffield; 6 from the boroughs and urban districts of Glamorgan—namely, Aberdare, Caerphilly, Ogmore and Garw, Port Talbot (each 1), and Rhondda (2).

Deaths.—In the aggregate of great towns (including London) there were 6 deaths from enteric fever, 9 from scarlet fever, 21 from diphtheria, 22 from measles, and 15 from influenza. In London itself the diphtheria deaths numbered 8.

THE LATE DR. R. T. JONES.—Dr Richard Thomas Jones, L.R.F.P.S. Glasg. and L.S.A. Lond, who recently died at his residence in Harlech, Merionethshire, began to practise in 1879. He received his medical education at Owens College, Manchester, and at Guy's Hospital, London, and settled in Wales, where he worked for 45 years. He was one of the first medical men in the Principality to advocate total abstinence on which subject he wrote several pamphlets. He was medical officer and public vaccinator for the Llanfihangel district of the Festiniog Union. For over 30 years he was district magistrate and was also High Sheriff of Merioneth.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT BRADFORD.

(Continued from p. 296.)

SECTION OF SURGERY.

WEDNESDAY, JULY 23RD.

ON the first day, Sir CUTHBERT WALLACE, the President, being in the chair, a discussion on

Acute Osteomyelitis

was opened by Mr. JOHN FRASER (Edinburgh). He began by pointing out the confusion which exists as to anatomical terms in relation to the structure of the bones, and defined the metaphysis as that portion of the diaphysis which lies adjacent to the epiphyseal cartilage. He said: The metaphysis is the site during the years of growth of the most intense cell activity and is the most vascular area of the bone. It is the site of origin of most of the inflammatory diseases of the bones, and in particular of acute osteomyelitis. This is essentially an infective process in the interior of the bone, the endosteum and the marrow being first affected. It is only at a later stage that the infection spreads through the bone and involves the periosteum. A primary periostitis is extremely rare. Acute osteomyelitis is then the result of an acute pyogenic infection of the metaphysis, and it is essentially an affection of the age of growth. In the vast majority of cases the infection is blood-borne, and this presupposes a mild form of septicæmia. That such a septicæmia occurs, and indeed is common in young children, the recent work of Lipschitz shows. The source may be any septic focus, in the teeth, tonsils, sinuses, or skin for example, or pneumonia and the exanthemata. An important source is the umbilicus, and Mr. Fraser referred to a series of 30 cases in young infants which he had collected in the last four years, all of them fatal. In his opinion umbilical infection is a common origin of obscure blood infection in infancy, the infection sometimes persisting until the years of later childhood. The disease tends to be localised in certain special sites, and in order of frequency these are the upper end of the tibia, the lower end of the femur, the lower end of the tibia, and the upper end of the humerus. Slight trauma is probably an important factor in causation, and this would explain the high proportion of cases in boys and in the lower limbs, but the trauma must be slight, probably resulting only in a small metaphyseal hæmorrhage. The large metaphyseal surfaces seem to be more readily affected than the small. Boys are affected more often than girls in the proportion of 6 to 1, and the eighth to the twelfth year is the period in which the disease is most common. In a series of 400 cases the responsible organism was the *Staphylococcus aureus* in 78 per cent., the pneumococcus in 14 per cent., and the streptococcus in 6 per cent. The number of cases of pneumococcal infection was an important point to be discussed later.

The disease starts in the metaphysis with an intense primary infection of the medulla. The inflammatory products are under extreme tension, and this accounts for the intensity of the local symptoms and the severity of the toxæmia which results. From the point of view of prognosis this is the most dangerous stage, for it is now that septicæmia in an acute form is most likely to occur. The second stage is evidenced by a spread of the infection from the interior of the bone into the subperiosteal area. The vessels and spaces of the Haversian canals are the routes along which the migration occurs, and a serous subperiosteal effusion is followed by a purulent one. With the relief of tension the symptoms abate and the prognosis improves. The facility with which the second stage can be established will depend on the number of the Haversian canals and the porosity of the bone, and the density of the femur may account for the severity of the symptoms associated with infections of this bone. The greater porosity of the tibia and the humerus makes it easier for the products of inflammation to escape from the interior of the bone. The third stage is that of reaction. The osteoblasts in the deeper layers of the periosteum proliferate, an involucrum is laid down, and the dead portion of the diaphysis is separated by the active phagocytic action of the granulation tissue which is formed.

The *clinical features* are intense and distinctive. There is the agonising pain of the early stage while the infection is still locked up under tension in the interior of the bone. It is during this stage that the signs of toxæmia—the high temperature, the delirium, the poisoned appearance—are greatest. It is at this stage that a massive invasion of the blood-stream may inaugurate a septicæmia which by its intensity overshadows the local signs. With the relief of tension which characterises the stage of subperiosteal effusion there is an immediate abatement of signs and symptoms, the pain diminishes, the temperature falls, the general appearance improves. But there is an element of danger in this stage because the sudden relief of symptoms may raise doubts as to the veracity of the diagnosis. Unless the condition is relieved by treatment the signs and symptoms are re-established as the tension again rises, and the features are now those of a local septic infection.

The *diagnosis* is usually established without much difficulty from the intensity of the local symptoms and the evidences of severe toxic absorption. In some cases the depth of the lesion may lead to difficulty. Thus osteomyelitis of the ilium may be mistaken for appendicitis or infection of the hip-joint. A blood count should avoid confusion with acute rheumatism, and cellulitis should be excluded by the less intense toxæmia by which it is usually accompanied. As regards prognosis, the more distal the lesion and the more porous the bone the better is the outlook. The real danger lies in the septicæmia which may develop in the first stage of the disease. The tendency to this is perhaps greater in young children.

The speaker was of opinion that in a certain class of case operation was neither necessary nor desirable. These were the cases described by pathologists as albuminous or serous osteomyelitis, a large proportion of which were produced by pneumococcal infection. In these cases operation in the early stages was likely to result in spreading the infection and in the production of necrosis. They usually occur in babies and young children, the temperature is rarely as high as in the ordinary suppurative osteomyelitis, the toxæmia is slight, and the neighbouring joint is usually the site of a serous effusion. A blood count shows that there is only a small degree of leucocytosis. In these cases operation should be delayed, and extension applied to the limb, with fixation splints and hot local applications. Under this treatment a large number of the cases will resolve, and even if suppuration ensues it is local in its extent. It is to be suspected if the temperature rises after a preliminary fall, if pain persists, or if local redness or œdema appear. Relief may be obtained by a single trephine opening over the focus of suppuration. In the ordinary cases, however, immediate operation is essential in order to cut short the grave risks of the first stage. A trephine opening is first made over the affected metaphysis, and this is followed by a series of openings along the shaft at intervals of three-quarters of an inch until healthy marrow is reached. The intervening bone is now cut away with a chisel, so as to fully expose the infected area, but the marrow is not touched at all, as scraping it only disseminates the infection and leads to necrosis of the bone. The wound is left widely open and Carrel-Dakin treatment is established. In three weeks it may be possible to close the wound partially by secondary suture. The speaker had tried the method of subperiosteal resection of the affected portion of the diaphysis, but has abandoned it except in those cases where the whole of the diaphysis has perished. He considered that it was likely to disseminate the infection, and that there was a real risk that a new bone would fail to develop. He regarded the method as justifiable only in late and neglected cases, such as should not now occur.

The *general treatment* of these cases has not received the attention it deserves. Regarding osteomyelitis as primarily a septicæmia with a secondary local focus, it is obvious that the general infection should receive adequate treatment. He advised the use of vaccines, commencing with 200 million of a stock staphylococcal vaccine, and going on to an autogenous vaccine as soon as possible. In grave cases a stock serum, a specially immunised serum, or ordinary horse serum are useful. Blood transfusion had given striking results, especially when combined with exsanguination, both in the very acute cases and in those in which septicæmia persists in spite of treatment.

Discussion.

The discussion which followed turned chiefly on two points—the avoidance of operation in mild cases and subperiosteal resection of the bone. Mr. B. C. MAYBURY (London) held that early operation is wrong in all mild cases and would not admit that expectant treatment should be limited to those where a pneumococcal infection was suspected. He regarded osteomyelitis as a localisation of a pre-existing septicæmia, and pointed to the widespread pain in the limbs which often occurs as a prodromal symptom as evidence of multiple abortive infections. His views were supported by Dr. T. W. LIPSCOMB (Sydney), who stated that in Australia, thanks to cleanliness and fresh air, acute osteomyelitis is rare, and that most cases clear up on expectant treatment. It is remarkable that even in this country cases among the upper classes are rare. It would appear to be essentially a disease of dirt and lack of nourishment.

Very divergent views were expressed as to the value of resection of the affected portions of the diaphysis. Mr. ALEX. MITCHELL (Aberdeen) and Mr. ACTON DAVIS (London) supported the method strongly as leading to a more rapid convalescence and to the formation of a solid core of bone instead of a hollow involucrum which might contain a persistent abscess cavity. Mr. Mitchell regarded it as the method of choice in severe cases where the bone was stripped of periosteum in the greater part of its circumference. He treats the resulting cavity by the Carrel-Dakin method, followed by secondary suture of the wound. He regards early movement as essential, and in the series of photographs which he showed the range of movement obtained was remarkable.

The general impression left by the discussion, in which Sir CUTHBERT WALLACE, Prof. G. E. GASK (London), and several other surgeons took part, was that in mild cases rest, extension, and hot applications might abort the disease, that in most cases a careful and limited exposure of the medulla is sufficient, and that in those cases where the periosteum is completely stripped from the whole circumference of the bone resection of the affected portion of the shaft is the most rapid and effective method. These last cases are, however, the result of neglect and ought never to be seen.

THURSDAY, JULY 24TH.

On the second day, Prof. G. E. GASK, Vice-President, being in the chair, a discussion on

Post-operative Pulmonary Embolism

was opened by Mr. J. P. LOCKHART-MUMMERY (London). He pointed out that the condition is probably much more common than is generally supposed, for probably nine out of ten cases recover, and that it seems likely that a large proportion of cases of post-operative pneumonia are really cases of pulmonary embolism. It may occur at any period after operation up to several weeks, but is most common about the ninth day. The average incidence of fatal cases is about one for every thousand operations. The onset is accompanied by acute dyspnœa and pain in the chest, but if the patient survives ten minutes the symptoms subside and he generally recovers. He will, however, have signs of a localised pneumonia, with rise of temperature, cough, rusty sputum, dullness, and tubular breathing. The distinction from ordinary pneumonia lies in the acute pain and dyspnœa of the onset, the comparatively low temperature, and the previous good health. Sudden death after operation may occur as the result of cerebral embolism, and it was shown by Wilson, of the Mayo Clinic, that 20 per cent. of such deaths were of this nature. It seems probable that the source of the embolus may be a primary pulmonary thrombosis. Where, on the other hand, a large area of the pulmonary arterial field is cut off the symptoms are those of severe cardiac embarrassment, and the dyspnœa is not due to the fact that part of the lung is put out of action but to the strain put on the heart by the sudden limitation of the area of pulmonary circulation. It follows that the administration of strychnine and stimulants during such an attack is entirely wrong and that the proper treatment is the use of amyl nitrite, morphine, and atropine. A loose clot passing through the right side of the heart may completely block one or both pulmonary arteries, or it may pass further on and come to rest in one of the smaller pulmonary arteries. In the former case death will ensue in a few minutes from the strain thrown on the right side of the heart, whilst in the latter the circulation will be cut off from a cone-shaped portion of the lung and symptoms of localised pneumonia will result. In any event the pulmonary embolism is a secondary condition, and the primary and important question is the source of the clot. In the few cases where definite evidence is available the primary clot has generally been formed in the internal or external iliac veins, or at their junction with the inferior vena cava. It has frequently been assumed, the speaker said, that the clot arises in the area of operation, but this is usually improbable and often impossible. The bulk of the fatal cases of pulmonary embolism have occurred where operations have been performed upon the gall-bladder or the viscera of the lower abdomen, and in the majority of these the venous return from the operation area was into the portal circulation. It seems, then, that the clot forms in the vena cava or its branches quite irrespective of the operation area, and that it is due to stasis in the great venous trunks rather than to any injury to contributory veins. It is a well-established fact that in almost all cases of pulmonary embolism the operation has been upon the abdomen or the lower limbs, and especially upon the pelvic viscera. It is suggested that the reason lies in the greater degree of immobility both during and after the operation than occurs in operation elsewhere. The position of the patient, and the pressure of retractors and packs, must tend to arrest the circulation in the inferior vena cava, and the interference with the action of the diaphragm will have the same effect. It seems probable that venous stasis is the most important predisposing cause of pulmonary embolism, and this would explain why anæmic patients are more prone to the condition, whilst in children it is practically unknown. The post-operative pneumonia of children is invariably of the broncho-pneumonic type.

There is no evidence to show, Mr. Lockhart-Mummery said, that sepsis plays any part in the occurrence of pulmonary embolism, except in so far as it may prevent movement or encourage the formation of intravascular clots. The great majority are clean cases with no evidence of sepsis at all. There must, however, be some other factor than stasis, for otherwise embolism would occur in paralysed persons, or even after normal sleep, and also we know by experiments that thrombosis does not occur with normal blood in a normal vein. The presence of thrombokinase is essential, but a certain quantity of this substance is liberated whenever a wound is made. Now it can be shown that thrombokinase produces clotting in intravascular blood only if the blood is stationary, and that it can be introduced in large quantities into circulating blood without effect. It would seem, then, that the formation of the clot which gives rise to pulmonary embolism depends upon two factors—the liberation of thrombokinase and the presence of stasis. As regards prevention, it is advised that purgation and starving before operations be avoided, that operating tables be fitted with mattresses, that constrained positions during operations should be avoided, and that every effort be made after operation to maintain a satisfactory circulation in the trunk and lower limbs.

Discussion.

The discussion was continued by Sir **CHARLES GORDON-WATSON** (London), who pointed out that the incidence of embolism, far from being reduced by improvements in surgical technique, had actually increased. At St. Bartholomew's Hospital in 29,000 operations there had been 21 fatal cases of pulmonary embolism. The underlying cause was thrombosis in the large veins occurring soon after operation, and embolism was actually less likely to occur in mild sepsis, since the clots which formed were more firmly attached to the walls of the vessels. Sudden movement was often the immediate cause of displacement of the clot, and he described a case of wiring of the patella for fracture where the patient made a perfectly normal recovery, was wheeled to the lift in a chair, and died in the lift as the result of a pulmonary embolus, the thrombus having been displaced by the sudden movement of the lift. He thought that the factors in the production of the thrombi were the release of thrombokinase in the wound, injury to the deep epigastric, the uterine veins, or other tributaries of the inferior vena cava, and hæmorrhage into the tissues, with resulting pressure on the veins. Predisposing causes were loss of fluid, lowering of the blood pressure, and the effect of posture on the venous return. He advised gentle operating, careful hæmostasis, the avoidance of extreme postures on the table, and the early commencement of massage and movement after operation.

Prof. **J. SHAW DUNN** (Manchester) gave his own experience of seven cases of pulmonary embolism, in each of which there was found in the pulmonary artery a large cast of the iliac veins. The thrombus having left its site of origin there was, of course, no abnormality found in the vein from which it had presumably arisen, but projecting into this vein there was found in each instance a small tag of clot arising in a small tributary vein, and on tracing this clot along the tributary it was always found to lead to the site of operation. In each of these cases a very mild localised sepsis *was* present, and it was pointed out how often thrombosis in a vein is associated with neighbouring sepsis. Thrombosis of the lateral sinus is commonly associated with middle-ear disease, of the pelvic veins with sepsis of the uterus, of the portal veins with a septic appendix.

Prof. **E. E. GLYNN** (Liverpool), in a very remarkable communication, stated his belief that a large number of cases described as pulmonary embolism are really cases of pulmonary thrombosis. A close examination of the lungs often shows a localised thrombosis, even where death has been so rapid as to suggest embolism as the only rational explanation, the duration of life in his cases ranging from 10 to 20 minutes after the acute onset. That the thrombus was not only ante-mortem but of some age was shown by the fact that frequently the arterial wall had absorbed pigment from the thrombus, and that in one case the pigment from a large thrombus in the heart had spread into the cardiac muscle. In a large proportion of the cases a non-hæmolytic streptococcus was found to be present in the thrombus. He believes that these thrombi form in the pulmonary artery itself, remaining latent until the lumen of the vessel has been narrowed to an extreme degree, when some small change in the position or form of the thrombus precipitates the final catastrophe.

Mr. **JAMES BERRY** (London) considered that the surest way to produce pulmonary embolism was to undertake a pelvic operation, to do it roughly, to tie off large masses of tissue in the immediate neighbourhood of large veins, and to keep the patient recumbent for some weeks. He advised very early movement after all operations on the trunk and legs, starting with chest exercises next day, combined with a regular arm drill. Prof. Glynn gave details of such a system in the gynæcological wards at Liverpool, and stated that the mortality from pulmonary embolism had been reduced from 4 per cent. to 1 per cent. of the whole operative deaths, whilst the mortality from this in the surgical wards, where this method had not been then adopted, remained constant. Whether the original site of these clots be in the systemic veins or in the pulmonary artery itself, such a system of exercises must necessarily reduce the possibility of stasis and the accompanying risk of thrombosis and of embolism

FRIDAY, JULY 25TH.

On the third day, Mr. **HAROLD BURROWS**, Vice-President, being in the chair, Mr. **T. P. DUNHILL** (London) read a short paper on

Auricular Fibrillation occurring in Toxic Goitre.

In cases of exophthalmic goitre referred to him irregularity of the heart was a not uncommon symptom, and in a number of these cases electrocardiographic tracings had shown that auricular fibrillation was present. In such cases it seemed rational to remove a portion of the thyroid and thus relieve the heart from this source of toxin. One case of this kind was that of a woman who had been seriously ill for 12 months with an irregular pulse, a loud systolic murmur at the apex, and swelling of the legs. Tracings showed well-marked auricular fibrillation. The right lobe and isthmus of the thyroid gland were removed under local anæsthesia, and three weeks later two-thirds of the left lobe. Her pulse dropped to 72, she became perfectly well, and she has remained so whilst following a strenuous employment. In all cases it is necessary, the speaker said, to remove a large portion of the thyroid tissue, usually the whole of one lobe and two-thirds of the other, but even then the fibrillation does not invariably clear up until a course of quinidine has been given. This is, however, a drug to be used with caution and only under expert medical supervision. In a large number of cases the combination of operation with quinidine results in rapid and permanent cure. It is, however, necessary to recognise that patients may have auricular fibrillation associated with goitre, in whom the goitre is not the cause of the fibrillation. A presystolic murmur or a history of rheumatic fever may assist the diagnosis, and the toxæmia of the typical thyroid is not present. But in many cases symptoms of profound thyroid toxæmia leave no room for doubt, the rapid pulse, moist warm skin, and staring, restless eyes. An investigation of the metabolic rate may give information of importance. If a portion of the gland is removed hyperactivity will be shown by the masses of cuboidal or even columnar cells which have replaced the flat cells lining the acini of the normal gland. This change in the form of the cells he regarded as the essential feature in the histology of Graves's disease.

Mr. **GEOFFREY KEYNES** (London) read a paper on

Blood Donors.

He referred to the important place which blood transfusion has since the war taken in surgical procedures, and pointed out that for its proper performance an organised supply of suitable donors was essential. They are often required in an emergency, when it is only too likely to happen that a suitable donor of the appropriate group cannot be found. Extensive experience has taught that a healthy young man can part with 750 c.cm. of blood, or even more, without any immediate effect, and that after a short rest he can perform an ordinary day's work as if nothing had happened. Fainting is psychological and is due not to the loss of blood, but to apprehension of the small operation involved.

It has, in fact, been noted that after a few days the donor feels in better and more vigorous health than before, and that he may even put on weight. The most suitable individuals are healthy men between the ages of 20 and 40. Women stand the loss of blood worse than men, and from a greater deposit of subcutaneous fat it may be more difficult to reach a vein in them by direct puncture, as should always be done. Perfect health and the absence of such infections as syphilis and malaria is essential, and this is another argument against the chance donor. It is generally thought that donors of group IV. can be used indiscriminately for any recipient, but this is probably only an approximation to the truth. In cases such as pernicious anæmia it is better to use a donor of the same group as the patient, and it is therefore well to have donors of all the groups available. In private practice there is no difficulty in providing donors. Suitable men are to be found quite willing to supply blood whenever required for a reasonable reward, and some of the professional donors give blood at intervals of six or occasionally even three weeks without inconvenience. In hospital, unless some system of payment can be organised, we have to depend on such casual donors as relatives or other patients in the ward. It has to be noted that consanguinity is no guarantee of compatibility of blood. Medical men and nurses should never be used, both on general principles and because their conditions of life are rarely productive of robust health. If medical students are used payment should be insisted on, as it is most undesirable that a sense of moral obligation should be induced. The speaker suggested that a properly organised supply of volunteer donors should be formed outside the hospitals among healthy individuals anxious to give personal service to the sick. Such groups might be found among Red Cross workers, who by character, training, and physique are peculiarly suited to the purpose.

Mr. H. P. **Winsbury White** (London) read a paper on

Hydronephrosis.

He pointed out that it is a fairly common surgical condition, rarely diagnosed until a late stage has been reached. It is most common in women, and between the ages of 20 and 50. The classical symptoms are rarely seen, and often intermittent pain is the only symptom. Sometimes a tumour may be felt, varying in dimensions from time to time, but it is only rarely that its disappearance is accompanied by the passage of a large amount of urine. Frequency is a symptom not of hydronephrosis but of the infection which is likely sooner or later to occur. Hæmaturia, from pressure on a vein, is not uncommon. The only final diagnosis of the condition is by means of a pyelogram. The concave lower border of the renal pelvis becomes convex, and this is followed by dilatation first of the upper calyx and then of the lower and middle calyces. In some cases large amounts of residual urine, 200 c.cm. or more, may be withdrawn by means of the ureteric catheter. In extreme cases of ureteric obstruction and stenosis it may be impossible to pass a ureteric catheter, and pyelography may thus fail. But in these cases there is usually a palpable tumour. Bilateral cases of hydronephrosis occur, and in these great caution is necessary before any operative treatment is undertaken. Infection is generally to be regarded as a contraindication to pyelography.

Mr. F. W. **Goyder** (Bradford) read a paper on

Hare-lip and Cleft Palate.

In regard to the former, he considered that it was unwise and unnecessary to remove the prominent premaxillary segment. Should it appear that the strain on the suture line of the lip would be too great if both sides of the lip were sutured at once, it was perfectly possible to suture one side at a time, leaving an interval of two or three weeks between the operations. In this way excessive tension was avoided and in the end the pressure of the lip would bring the premaxilla back into place. A sliding operation on the septum was fraught with risk to the vitality of the premaxilla. In regard to cleft palate, he considered that too much stress had been laid on closure of the cleft and too little on the obtaining of clear articulation. For the latter it was essential that it should be possible to approximate the soft palate to the back of the pharynx, and in order to do this satisfactorily it was in some cases necessary to forego closure of the hard palate. The aperture left could, however, be easily closed by means of an obturator.

SECTION OF PUBLIC MEDICINE AND INDUSTRIAL DISEASE.

Wednesday, July 23rd.

The Rôle of the General Practitioner in Preventive Medicine.

Dr. **Herbert Jones**, the President, in his opening remarks, drew attention to the fact that this was the first annual meeting at which the public health service, as represented by the Society of Medical Officers of Health, had been formally admitted to the B.M.A. representative meeting and its Council, and that there was now reciprocal representation of the Association on the Council of the Society. The Association had concerned itself much with the interests of the public health service, but it and the Society had not always travelled along parallel lines. There had sometimes been a tendency to make a sharp distinction between curative and preventive medicine. In his opinion there should be no distinction, and this section ought to be able to indicate how the general practitioner and the medical officer of health can help each other. The first medical officers of health were of necessity drawn from the ranks of the general practitioner and their success was largely due to the fact that they were conversant with the difficulties of the general practitioner. For a long period the medical service of the Local Government Board was recruited from the ranks of medical officers of health, and thus obtained insight into the methods and idiosyncrasies of local governing bodies. The public health service was proud of its achievements, but it fully recognised the help given by the marvellous triumphs of the physician and surgeon and of the laboratory worker. They needed the complete and intelligent coöperation of the general practitioner and the medical officer of health. The aim of both was the welfare of the community, and in the words of a great English novelist, " What is life for if not to make the world less difficult for one another ? "

The discussion was opened by Dr. **Peter Macdonald** (York). Commenting on the dictum, " The first duty of medicine is not to cure disease but to prevent it," he said that if Sir George Newman had substituted " ought to be " for " is " all would have agreed, but as the words stood they were exactly the opposite of the practice of the past and of the present, for most practitioners devoted their lives to the cure of disease already there and not to its prevention. Preventive action taken by the general practitioner was, so to speak, unofficial. Why was this ? The answer was obvious. Until recently the economic demand on the medical profession had been and still was for cure. Only within recent years had they begun to prevent, and still more recently had they been asked to prevent, and some of them paid to prevent. The receipt of their emoluments from people who were ill was a highly unstable proposition, and thus the club system arose as a semi-charity. The club system somewhat shifted the economic outlook. In 1912 the club system was enlarged on a grand scale into the National Health Insurance Medical Service, and thus incentives were given for preventive work which did not previously exist. He would deal with the present preventive activities of the general practitioner under several heads.

Early Treatment.—It was obvious that early treatment of one disease prevented others. The vaccination of contacts, the prophylactic administration of antitoxin for diphtheria and precautions against ophthalmia neonatorum were examples of what might almost be called early treatment, and naturally led up to advice on personal hygiene and protection of the other members of the family from disease.

How does the General Practitioner Fail to take Advantage of his Preventive Opportunities?—The answer is, he does not interest himself sufficiently in matters of bad environment which hinder his curing disease. Atmospheric pollution, bad housing conditions, bad work conditions, adulteration of food, alcoholic excess, all hinder cure and so become the concern of the general practitioner. The general practitioner could do much to stir up public opinion on matters like smoke pollution, which only existed owing to the ignorance and apathy of the community. The general practitioner ought also to educate public opinion on all matters of bad environment. At present the influence of the medical profession in Parliament and on local authorities was negligible.

Aims for the Future.—Houses built to live in are, generally speaking, not suitable to be ill in. To obtain the best from him the general practitioner must have hospitals in which to do more of his work. Childbirth was in every way better conducted in a nursing home than in a private house, and the nightmare of midwifery practice in a workman's cottage, with even two or three bedrooms, was good neither for the mother, the child, the doctor, nor the community. The provision of hospital beds in the country was grossly inadequate. In the second place, it was absurd that a medical service had been set up for the fathers, but did not include the mothers and children. If the National Health Insurance Service, which at present included one-third of the working-class people, were extended to the other two-thirds, the preventive aspect would be enormously increased. Thirdly, his knowledge of the work of pensions medical boards led him to the conclusion that this idea might be usefully applied to insured persons generally. The advantages of periodic examination of insured persons by boards would be great from the preventive point of view, but he was doubtful if public opinion was ripe for such a step.

Links between the General Practitioner and the Public Health Service.—He thought that in all the encroachments at present being made by the local and national public health authorities on the domain of the general practitioner, the maximum use should be made of the general practitioner by means of "part-time" service.

New Thoughts Influencing the Outlook on Health.—He had been interested in the writings of F. M. Alexander, H. C. Cameron, and W. A. Cochrane, pointing to the fact that health, physical and mental, depends upon a coördination of the whole body, which will make man largely superior to his environment, and for the general practitioner there will be a pre-eminent place in the application of such principles.

Discussion.

Prof. **Harold Kerr** (Newcastle-on-Tyne) said the general practitioner's want of interest in preventive medicine was partly due to the fact that public health was not attractively put before medical students. From the point of view of the general practitioner the medical officer of health used to be regarded as "not a proper doctor," "a kind of genteel plumber," and more recently, "a patient-snatcher." Sir George Newman had laid emphasis on our ignorance of natural processes, and there was no doubt that applied physiology was inadequately taught. The family doctor was in a good position to recommend improvements in environment. Little troubles were important. For example, constipation was promoted by nasty privies. Local divisions of the B.M.A. might do much to educate public opinion. He believed in "part-timers." Many of the recent whole-time appointments were cul-de-sac jobs, but part-timers must take their work seriously. He found that general practitioners did not sufficiently encourage breast-feeding.

Dr. **F. E. Fremantle**, M.P., thought there would ultimately be a place for health specialists in the latest applied physiology. The general practitioner might have great influence on public opinion, but there was no proper organisation for backing up the public health service or making the weight of medical opinion felt in Parliament.

Dr. **J. S. Manson** (Warrington) pleaded for sympathy with the difficulties of the general practitioner.

Dr. **F. E. Wynne** (M.O.H. Sheffield) had to thank the general practitioner for recent help in dealing with outbreaks of small-pox and encephalitis lethargica. In Sheffield they employed a "part-time" staff at the maternity and child welfare centre with satisfactory results. The general practitioner had not yet been able to wean the public from that extraordinary fetish, the 6 oz. bottle of medicine.

Dr. **H. B. Brackenbury** (London) said the general practitioner was the only person in a position to deal with preventive medicine of the whole organism. The use of vaccines was likely to extend and the work of the general practitioner to become more and more of the nature of personal and domestic hygiene. It was also extending to hygiene of the workshop. An increasingly close association was needed between the staff of the M.O.H. and the practitioners. The general practitioner must be given his opportunity. He needed time and money to investigate early disease and give prophylactic advice. This could be obtained by raising the capitation fee and thus allowing him to do more work on a smaller number of patients.

Dr. **J. R. Kaye** (M.O.H. West Riding) stated that 37 general practitioners worked in the centres established by the West Riding County Council. During health week last year 154 general practitioners gave lectures. In order to secure early notification of disease he had found provisional notification a useful procedure.

Dr. **David McKail** (Glasgow) said the "part-timer" was not utilised in Scotland. There were none in Glasgow. He pointed out the disadvantages of inexperienced whole-timers, and went on to say that there was insufficient coördination between the work of health centres and that of the parish authorities.

Dr. **Lockhart Stephens** (Warblington U.D.C.) said education was the keynote of preventive medicine. He believed that post-graduate courses in infant feeding for the general practitioner would do much good.

Dr. **H. Scurfield** asked who was going to carry out the new preventive midwifery. The new midwifery required more obstetrical skill and experience than emergency midwifery, and the general practitioner was doing less and less midwifery. It seemed to him that midwifery would fall into the hands of a panel of obstetricians, perhaps mostly women, who would act in coöperation, and not in competition, with the general practitioner.

Sir **Malcolm Watson** (Malaya) was surprised at the lack of unity in the profession at home. In 24 years they had made great progress in Malaya. They were now actually doing some antenatal work. Beri-beri had been controlled, and cholera and small-pox abolished, because it was obvious to the employers that these diseases interfered with the work of the plantations.

Dr. **Cecil Williams** (Todmorden) said the school medical officer and the general practitioner ought to coöperate in the first line of defence against disease. Some agreement as to what should be required of any general practitioner booked for a confinement was long overdue.

Dr. **N. R. Rawson** (Whitley Bay) said there was a want of coöperation on the part of the medical officer of health. The B.M.A. Division should act as the link.

Dr. **J. Hall-Edwards** (Birmingham) read a paper setting out what action the local authority might take in the control of cancer. He advocated the appointment of a committee in every large city to review periodically questions relating to cancer and to consider what steps should be taken to meet the requirements of the public and the medical profession. The first of these steps was compulsory notification.

Dr. W. Mitchell (i/c Electr. Dept., Bradford Royal Infirmary) considered that no man should be a specialist unless he had had some experience in general practice. He asked if cancer was less among Jews and Jewesses owing to the observance of the Mosaic law.

Dr. R. W. Stocks (West Bromwich) believed that coöperation between general practitioners and the public health service in his district was promoted by the fact that he and his assistants on their appointment called on all the medical men in the district. It had been an advantage to bring public health subjects, such as the use of the Schick test, before the B.M.A. Division. "Part-time" work at the infant welfare centres had been discontinued at the request of the general practitioners.

The whole discussion indicated a very good feeling between the general practitioners and the public health services, and a desire for closer coöperation. Before the session closed a resolution was passed asking the Council of the Association to institute an inquiry as to the best means of applying the experience of the profession to the work of Parliament.

THURSDAY, JULY 24TH.

Diet and Public Health.

Dr. J. Boyd Orr introduced this subject with a paper descriptive of the research work recently done at the Rowett Institute, Aberdeen, of which he is director. He expressed the opinion that there is now sufficient knowledge and sufficient interest to make dietetics an important factor in preventive medicine. During the past two or three years there had been a tendency to regard the evil effects of deficient dietaries as being due chiefly or entirely to the want of vitamins. It was now being recognised, however, that the amounts and proportions of the inorganic elements of the diet were of fundamental importance to the maintenance of health. It was impossible to make an unqualified statement as to the absolute amount of any mineral needed in the diet because many factors influenced its absorption or excretion. For example, it had been shown that an excess of potassium in the diet caused an increased excretion of sodium, and that the potassium-sodium ratio in the diet affected the assimilation of calcium and phosphorus. An excess of magnesium also interfered with the utilisation of calcium and so on. The first line of defence against rickets was the adjustment of the mineral contents of the diet. It was probable that calcium deficiency was common in infancy and early childhood, and was not only an important ætiological factor in rickets, but also in many other diseases associated with defective nutrition. A deficiency of iron was likely to be found in young children restricted to a diet of milk and refined cereals. The possibility of the deficiency of iodine was also worthy of consideration. In laying hens they found that iodine seemed to have an influence on calcium metabolism. Fortunately, mineral deficiencies could be easily corrected by including in the diet food-stuffs the virtues of which are universally recognised. Thus milk, green vegetables, and certain fruits were rich in calcium; milk, egg-yolk, and the embryo and bran of cereals were rich in phosphorus; green vegetables and egg-yolk were rich in iron. The only certain sources of iodine were green vegetables and cod-liver oil. Fruits and vegetables had an excess of alkali and could be used to correct a diet which was too acid. In his opinion much of the beneficial effect ascribed to vitamins was really due to the minerals present in the substances given as a source of vitamins. Of course, the inorganic constituents of the diet were only one aspect of nutrition, and further factors not connected with the diet, such as sunlight, exercise, and psychological influences, had to be taken into account.

Dr. J. S. Manson contrasted the robust and healthy appearance of men home on leave during the war and after the armistice with the deteriorated appearance and loss of weight of the same men within a year or so after their discharge from the services. He attributed the change to the inferior home dietary as compared with the service dietary.

In a paper on Diet Control as an Instrument of Public Health Progress, Dr. W. G. Savage (M.O.H. Somerset) expressed a very decided opinion that there was no measure likely to yield a better harvest in the improvement of the health of the community than education of the people in sound food habits. Our people persisted in faulty dietetic practices because no adequate steps were taken to enlighten them. The pessimist would declare that this was not practicable. The same was said with regard to infant feeding and rearing, but this had been refuted in the last few years. The application of similar educational measures to the whole of the public could be accomplished with greater difficulty but probably with equal success.

Dr. Robert Hutchison (London) was not satisfied that deficient diet or prolonged illness in infancy had a permanent effect on the physique of the individual. Infants brought to death's door by congenital pyloric stenosis often developed into fine children later on. He thought a deficient diet about the time of puberty was more likely to have a permanent effect. He could not see that a defective diet after being discontinued was likely to leave permanent effects on the heart, nervous or digestive system, or on the resistance to disease.

Dr. J. B. Simpson (Golspie) thought the physique of the crofters in the Highlands had deteriorated as the result of a change of diet. Tea and white bread and jam had taken the place of porridge and milk.

Dr. H. Scurfield believed that the national physique could be greatly improved by a better dietary. He thought legislation was required to regulate the use of preservatives in food; to enable us to know what we were getting when we bought flour or bread; to prevent foods being sold under misleading names, and to control infants' starchy foods. He thought we should not tie ourselves down with shibboleths about "natural foods," &c., but apply the knowledge we possessed to determining the essential goodness of every food at present used by man. It was very important that we should concentrate for the benefit of the public on the points on which we were agreed. For example, we were practically unanimous as to the need for more milk, vegetables, especially green vegetables, and fruit. Such advice would be approved both by those who were doing research work on vitamins, by those who, like Dr. Orr, attributed great importance to the mineral salts, by dentists, and by the crusaders against constipation.

Dr. A. L. Hoops (Malaya) said that beri-beri had been abolished in institutions by the prohibition of over-milled rice. It still existed and ravaged the general population because the labourers liked over-refined rice. Attempts to prohibit its use had led to riots. In the country districts, where under-milled rice, fruit, and vegetables formed the staple articles of the dietary, teeth were good, but in Singapore, where over-milled rice and white bread (with no milk) were in use, the children had very bad teeth. There was no rickets in Malaya, and this was attributed to the sunshine.

Dr. J. J. Paterson (M.O.H. East Berkshire Combined District) referred to the huge experiment in starvation experienced by Austria. The results appeared to be marked indelibly on the school-children. One could guess the year of their birth from their appearance. Every third child had a goitre. Fats and natural foods were at one time almost unobtainable. Could these effects be corrected by time? He hoped some systematic effort would be made to keep medical records of the progress of this vast involuntary experiment.

Dr. Orr, in replying, said it was impossible to be dogmatic as to whether the lessened resistance to disease caused by a bad diet leaves permanent effects, or can be worked off by the substitution of a good diet. He agreed with Dr. Scurfield that it was very necessary for us to attain the utmost possible unanimity in our advice to the public.

Industrial Welfare.

The President, Dr. Herbert Jones, in opening the discussion, referred to the pioneer work of Josiah Wedgwood (who provided houses and an open-air swimming bath for his employees) and gave the following apt quotation from his biographer: "To be comfortable himself he must know that those around him were comfortable also. To be happy he must impart happiness to others even to the most lowly of his employees. To sit at ease in his own new home he must know that those he employed were well and cosily housed. He therefore set about building a village for his workmen and their families." Wedgwood's works were established in 1767.

Dr. W. F. Dearden (M.O.H. Port of Manchester and Certifying Surgeon) contributed a useful paper, giving an epitome of the multifarious activities included under the term "industrial welfare work." The war had been a great stimulus to this work. If properly applied industrial medicine could bring about an immense saving in lost time through industrial convalescence and through the better suiting of a worker to his job. There would, perhaps, never be the same demand for whole-time works doctors as there was in America, although he had no doubt that industrial welfare work had come to stay, and that there was a great future before it.

Dr. McKail said that for adult men good working conditions and wages were the chief need. For young persons and women at all ages industrial welfare was a necessity. For boys and girls an officer was needed to make adjustments in their working conditions. The elder children of a working-class family were especially likely to be under-fed, and needed careful supervision.

Dr. G. T. Willan (Carr and Co., Carlisle) said a whole-time works doctor was good for a medium-sized firm like his, which employed from 2500 to 3000 workers. At first his appointment was viewed with suspicion by the panel doctors, but they soon found there were no grounds for that view. By immediate treatment of illness and slight injuries, employees were prevented from going on the sick list. If they had to go sick a note was sent to the panel doctor. A works doctor was no good without a proper welfare department. The system reduced absenteeism, promoted good feeling, and filled the gap in medical supervision between the ages of 14 and 16. There was a great decrease also in compensation, and it was frequently possible to find suitable jobs for injured workmen who, without such a system, would be off work for prolonged periods.

Dr. T. W. Sinclair (Melbourne) was impressed with the arrangements made in some of the American factories for recommending sound dietaries to their employees. Sometimes also there was a free distribution of milk.

Mr. George Armstrong (Bradford Dyers Association) said the Runciman Act of 1910, with regard to choice of employment, was not properly worked. The Day Continuation Schools Act of 1918 was not yet in operation. Many a boy obtained employment who was not physically fit for it, and many a man was not properly fed for his job. Diet was very important. The health records were not yet transferred from the schools to the factories. In this movement it was essential to have the workers with them.

Miss Shute (Listers, Bradford) said the 14 to 16 year olds were a great difficulty. The child comes to work in good health but great physical deterioration takes place in the next three years.

Mr. Reginald J. McKay (Bradford Dyers Association) mentioned that at one of their Bradford works a new ophthalmic service had been instituted. The firm provided plain glasses, and if the workers wanted more elaborate ones they paid the difference. As an example of the need for this service they found that in the past they had spent futile years in trying to train colour-blind workers. There was a considerable movement for vocational and psychological tests. There must be coöperation as to the medical and psychological examinations.

Dr. J. J. Robb (Bournville) said there was a tendency in America now to realise that one may over-coddle. Only a small percentage of the employees took advantage of the playing fields and facilities for recreation. In some way the factory doctor must be made independent of the firm in order to get the best results. The independence of the worker must be encouraged. Industrial welfare work should be a national responsibility. The worker is fearful of becoming a mere cog in the machine.

Dr. T. Watts (Manchester) regretted that compulsory industrial welfare had not been included in the new Factory Bill.

The trend of the discussion was to emphasise the importance of, and great future before, the movement, coupled with a note of warning against over-paternalism. A noteworthy feature of the discussion was the part taken in it by the trade representatives.

SECTION OF ORTHOPÆDICS.

Friday, July 25th.

This section met on one day, with the President, Mr. R. C. Elmslie, in the chair, to discuss the

Treatment of Hallux Valgus and Rigidus.

Sir Robert Jones (Liverpool), who opened the discussion, referred first of all to some points in the ætiology of the disabilities under consideration. In his opinion, boots were the exciting cause of the vast majority of cases of hallux valgus. He contrasted the primitive foot as seen in the infant, or the adults of barefooted races, with the foot of the average civilised individual. In hallux rigidus, whilst static causes might operate in the production of the deformity, injury was usually a dominant ætiological factor. Patients rarely sought aid because of deformity alone, but usually owing to progressive pain and discomfort. On careful examination the actual causes of the pain complained of were found to vary in different individuals—e.g., (*a*) inflammation of the bursa, (*b*) arthritis, (*c*) osteophytic pressure on the digital nerves, (*d*) callosities under the joint. An appreciation of such distinctions was necessary in order that appropriate treatment might be applied.

Treatment of hallux valgus was considered under three heads: (1) Preventive.—When a patient asked for advice in the postural stage of the deformity, he was instructed to wear shoes built on correct lines. Operative treatment was rarely if ever desirable for æsthetic reasons alone. (2) Mechanical.—It is essential to relieve the joint from pressure and this could be ensured by the simple device of placing a transverse bar of leather across the sole just behind the metatarso-phalangeal range. In addition it is advisable to tilt the inner border of the heel as in the case of simple flat-foot. Where the bursa was inflamed complete rest was prescribed. In many patients conservative methods brought about the relief of the major symptoms, and operation was not required. (3) Operative.—The choice of the operation should be decided by the special circumstances of the case. In the milder cases simple division of the joint capsule and the extensor proprius hallucis tendon, with or without cuneiform osteotomy of the neck of the metatarsal, would often suffice. Where the symptoms were entirely referable to the bursa, exsection of the sac and the underlying exostosis was necessary. Excision of the head of the metatarsal was an operation of great value, which should be reserved for patients of middle age with arthritic changes, but in exceptional circumstances might be practised in younger individuals. In the latter the weight-bearing portion of the head should always be left. Resection of the base of the first phalanx was an operation which might be regarded as a valuable alternative.

Treatment of hallux rigidus.—For this condition the operation of choice was removal of the base of the first phalanx. After all operations it was necessary to give a period of treatment directed towards the development of the musculature of the foot.

Mr. E. LAMING EVANS (London), who followed, laid stress on the importance of focal sepsis as an ætiological factor in hallux valgus. He advocated, and practised regularly, the operation of excision of the metatarsal head. There was no interference with the stability of the foot if the stump of the neck was brought to rest on the sesamoid bones. Mr. Evans regarded the post-operative re-education of the foot musculature as an essential part of the treatment.

Mr. D. MACRAE AITKEN (London) supported the view that the deformation began in early life and was due to static errors. Contrary to general experience he had found that the operation of cuneiform osteotomy of the neck of the first metatarsal was followed by good results.

Mr. NAUGHTON DUNN (Birmingham) agreed that it was necessary to institute a careful inquiry as to the exact causation of the pain. He recognised two main types of case: (a) Where the pain was due to pressure; in these, trimming of the metatarsal head was sufficient. (b) Pain due to joint movement only. Here he practised excision of the metatarsal head, or of the base of the phalanx, according to the age of the patient.

The PRESIDENT expressed his belief that compression of the forefoot in improper shoes was the outstanding factor in the ætiology of hallux valgus and rigidus. Re-education of the smaller foot muscles was therefore an integral part of all treatment. In the choice of an appropriate operation, every case had to be judged on its merits. In his experience the best results had followed complete excision of the metatarsal head, or in less severe cases, trimming of the head. After this operation the foot should always be strapped so as to support the anterior metatarsal arch.

Mr. P. BERNARD ROTH (London) emphasised the part played by the following ætiological factors:—(1) tight socks in children; (2) trauma; (3) heredity; and (4) infection. He favoured the operations of simple trimming of the metatarsal head or complete excision.

Mr. W. ROWLEY BRISTOW (London) stated that a survey of the results of the cases operated on in his clinic had shown that excision of the metatarsal head gave exceedingly good functional results. He was less satisfied with the results obtained after the operation of simple trimming.

Dr. G. HOLMES (Harrogate), who confined his remarks to conservative treatment, laid emphasis on the value of paraffin baths for the subjective symptoms of pain and discomfort.

The Operative Treatment of Arthritis Deformans of the Large Joints.

Mr. HERBERT FRANKLING (Harrogate) read a short communication on the results obtained in a personal series of operations on the hip- and knee-joints in cases of arthritis deformans. The cases were carefully chosen and the operations were conducted only after a long period of medical treatment. He stated that it was important to approach each operation as an exploratory procedure with no fixed routine in mind, the actual technique being determined after a careful inspection of the interior of the joint had been made. His results had been carefully analysed and it was gratifying to know the degree of comfort and mobility which had developed in a number of cases after comparatively conservative operative measures.

Acute Arthritis of the Hip.

Mr. S. T. IRWIN (Belfast) described a series of cases of acute arthritis of the hip-joint in which mechanical problems of considerable difficulty were presented in the later stages. He pointed out that if in this condition and similar acute infections early correct splinting and postural treatment had been employed, many of the later difficulties would never have arisen.

Lesions of the Ulnar Nerve in the Region of the Elbow.

Mr. HARRY PLATT (Manchester) dealt with some points in the pathogenesis and treatment of certain forms of ulnar nerve lesion in the region of the elbow, which he divided into three classes: (1) Lesions associated with recent fractures of the lower end of the humerus. An ulnar nerve lesion accompanying a fracture of this type was an uncommon complication, and usually was a transitory phenomenon. If the signs of severe neuritis persisted operation was indicated, and the nerve should be displaced to the front of the elbow. (2) Late involvement of the ulnar nerve. For this condition, in which various types of reconstructive operations had been practised, the operation of anterior transposition of the nerve was also effective. (3) Recurring dislocation of the nerve. Here again the operation of anterior transposition should be regarded as a routine procedure.

EXHIBITION OF INSTRUMENTS, DRUGS, FOODS, AND APPLIANCES.

BRIEF mention has already been made of the very varied and complete exhibition of surgical instruments, appliances, drugs, foods, and other objects of medical interest, which was held in the Windsor Halls, Morley-street, Bradford, from Tuesday, July 22nd, until Friday, July 25th. The educational value of such an assemblage was the subject of Mr. Basil Hall's remarks when, as President of the Association, he opened the exhibition, and the attendance throughout the week showed that his view was taken by many of those who were attending the meetings.

SURGICAL INSTRUMENTS AND APPLIANCES.

The exhibit of surgical instruments, general and special, was as full and instructive as in recent years, with a number of ingenious contrivances of the last 12 months added. [49] Allen and Hanburys, Ltd. (Bethnal Green, London, E.C. 2): an extensive surgical exhibit, including a model of the new St. Bartholomew's Hospital pattern operation table, the minimum height of which has been reduced to 32 inches, and which includes a new arm-rest for support during removal of axillary glands, and an arm-support for use in the kidney position. Among other recent models were the latest pattern of Boyle's gas, oxygen, and ether apparatus, insulin syringes as made for Dr. Leyton, the newest forms of blood-transfusion apparatus, and sets of electrically illuminated diagnostic instruments.—[6] Arnold and Sons (John Bell and Croyden, Ltd., 50, Wigmore-street, London, W. 1): an improved operation table, at a moderate price, on an oil-pump base, the whole control of which is from the head end of the table, within the surgeon's easy reach; also a new self-retaining abdominal retractor, designed by Mr. H. B. Devine, of Melbourne, giving an extensive view of the field of operation.—[44] Down Bros., Ltd. (21, St. Thomas's-street, London, S.E. 1): a large and representative collection of surgical instruments and appliances, including recent introductions and modifications suggested by surgeons, many of the instruments being made in stainless steel—e.g., Childe's crushing clamps and forceps; Fraser and Dott's guillotine for aseptic intestinal anastomosis; Ryle and Einhorn's tubes for gastric and duodenal analysis; instruments for lung surgery by Duval, Tuffier, and de Quervain.—[27] The Holborn Surgical Instrument Co., Ltd. (26, Thavies Inn, London, E.C. 1): an exhibit covering most branches of modern surgery, of special interest being a pocket record syringe to be readily carried about, sterilised in a water-tight container, and a simple and ingenious form of pantoscope, both listed at very moderate price.—[25] Mayer and Phelps (59, New Cavendish-street, London, W. 1): a selection of instruments and apparatus of original design for general and regional surgery, including a very practical form of blood-pressure outfit with arm-band and dial; and Daniell's apparatus for administration of warmed ether vapour. An extremely rigid operating table by this firm is on view at the Wembley Exhibition. Point was made of an absolutely boilable silk of unbleached fibre.—[54] Reynolds and Branson, Ltd. (Leeds): a large exhibit of special instruments, including those used by Sir Berkeley Moynihan in abdominal surgery, most instruments being in stainless steel, not excepting the knives themselves. A set of apparatus and solutions designed for the use of the general practitioner in the diagnosis of glycosuria and diabetes. —[24] C. F. Thackray (Gt. George-street, Leeds, and 119, High Holborn, London, W.C. 1): a collection of abdominal and surgical instruments, including Rufus Harris's extension apparatus with a spring balance up to 25 lb. applicable to any Thomas's splint, obviating the use of pulleys and uprights, and not pinning the patient down to the bed.—[2] John Weiss and Son, Ltd. (287, Oxford-street, London, W. 1): besides a complete display of instruments, including many new and original designs, a very practical projection lamp for throwing on the screen any microscopic slide and giving a 7-foot disc in a dark room with an ordinary wall-plug attached to a lighting circuit. Also a new epidiascope with no filament.

Among the special instruments:—[15] Ajax Electro-Medical Apparatus (117, Central-street, London, E.C. 1): with special emphasis on a new sinusoidal generator requiring only a little water from the tap to render it capable of furnishing a wide range of currents for treatment.—[20] Ardente Acoustique (Mr. R. H. Dent, 95, Wigmore-street, London, W. 1): in addition to a series of apparatus for the relief of deafness characterised by absence of adventitious sounds and metallic timbre, a stethoscope specially designed for doctors suffering from deafness, and a church installation rendering it possible for deaf people to hear the service from any part of the building.—[3] The Dowsing Radiant Heat Co., Ltd. (91, Baker-street, London, W. 1): the latest form of apparatus for giving radiant heat treatment by means of luminous rays, with a bed of new design and simpler construction.—[36] The Genito-Urinary Co., Ltd. (64, Great Portland-street, London, W. 1): a selection of cystoscopes, urethroscopes, bronchoscopes, œsophagoscopes, of various types, including the latest improvements and the inventions for diagnosis and treatment associated with the names of Thomson-Walker, Swift Joly, Frank Kidd, A. C. Morson, and others.—[32] Theodore Hamblin, Ltd. (15, Wigmore-street, London, W. 1): a number of ophthalmic instruments, including a new luminous Morton ophthalmoscope to be used with both the direct and indirect methods, and a new prismatic binocular loupe giving a large flat field with three magnifications.—[43] Rayner and Keeler, Ltd. (dispensing opticians in London, Bradford, Liverpool, Leamington, and other towns. Works: Kemp Town, Brighton): a luminous ophthalmoscope with standard Morton body and improved May type of illumination; an operating lamp with triple beam mounted on adjustable sling support; and a new fitting of the Moorfields lamp giving an intense beam for needling which can be used also as a slit lamp.

Besides those firms mentioned as supplying dressings:—[47] Antiphlogistine (Denver Chemical Manufacturing Co., London, E.C. 3): the well-known hygroscopic antiseptic poultice for use in inflammatory and congested conditions both superficial and deep-seated.—[34] Thermogene Curative Wadding (The Thermogene Co., Ltd., Haywards Heath, Sussex): a scientifically prepared cotton-wool impregnated with various medicinal essences, intended to stimulate gently the circulation in the affected part.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

The collection of drugs and pharmaceutical preparations was, as usual, large and representative, containing for the most part new and improved forms of well-tried remedies rather than a host of new synthetic drugs. [49] Allen and Hanburys, Ltd. (37, Lombard-street, London, E.C. 3): the pharmaceutical section of this firm's exhibit included insulin A.B. brand, with a special set of apparatus and reagents for the estimation of blood-sugar by Maclean's method; the various forms of Allenburys foods for infants, and diabetic flour; numerous polyglandin preparations and osmokaolin prepared by electro-osmosis, in colloidal form, for the treatment of intestinal toxæmias.—[55] Boots Pure Drug Co., Ltd. (Station-street, Nottingham): amongst a large exhibit of fine chemicals, tablets, pastilles, tinctures, were specially to note insulin, acriflavin, stabilarsan, and chloramine T. Details were available of the strict system of analyses made by expert chemists in the firm's laboratories before the use of any raw material, of the running control during manufacture, and examination after packing.—[46] C. J. Hewlett and Son, Ltd. (35, Charlotte-street, London, E.C. 2): a number of well-established original preparations, including deliciol, a coloured and flavoured soft paraffin; evapogens, a medicated evaporating skin lotion; iodermiol, a non-irritating preparation of iodine; and Dr. Crofton's human tubercle bacillus solution on which demonstrations were being given.—[56] The Hoffmann La Roche Chemical Works, Ltd. (7, Idol-lane, London, E.C. 3): besides the well-tried sedobrol, in tablet form for preparing a hypnotic bouillon, and omnopon in various forms, a new non-narcotic, non-habit-forming hypnotic and analgesic was shown bearing the name allonal, coming with recommendation from the Jefferson Medical College, and spasmalgin, a combination of omnopon, papaverin and atrinal, for relieving pain in dysmenorrhœa and colicky conditions.—[38] Oppenheimer, Son and Co., Ltd. (179, Queen Victoria-street, London, E.C. 4): besides the palatinoids, bipalatinoids, pulverettes, and various roboleine compounds, an oxygen generator and oxinhalator, providing oxygen gas from chemical cubes in a high state of purity, for use in country districts and under circumstances where cylinders of compressed gas are not available.—[50] Parke, Davis and Co. (50, Beak-street, Regent-street, London, W. 1): in addition to a large variety of pharmaceutical and toilet preparations, bacterial vaccines prepared in the Department for Therapeutic Inoculation at St. Mary's Hospital, anti-diphtheritic serum containing 1400-1500 units per c.cm, Dr. Owen F. Page's tuberculin insufflation outfit, as well as hæmoplastin, a sterile fluid for venous injection, reducing the coagulation time of the blood.—[54] Reynolds and Branson, Ltd. (Leeds): among a large exhibit in this class, concentrated emulsions for making medicated waters more cheaply than on a spirit basis; unguentum sedativum R. & B., a healing and antiseptic ointment containing calamine and pitch, of proved utility in many skin affections.—[4] Sandoz Chemical Co., Ltd. (Canal-road, Bradford): scillaren, femergin, felamine, and ipecopan in tablet form, as well as a useful dietetic and digestive biscuit known as matinol, incorporating highly refined petroleum to the extent of some 20 per cent., an elegant regulative medium.—[14] E. R. Squibb and Sons (80, Beekman-street, New York): thromboplastin, a lipoid prepared from the brain of the ox, by Dr. A. F. Hess's method; and thyroxin, a physiologically active ingredient of thyroid, containing 65 per cent. of iodine.—[40] W. A. Wharram, Ltd. (31, Lady-lane, Leeds); a series of popular pepsin preparations, the digestive ferment being combined in various ways with bismuth, nux vomica, strychnine, iron and aromatics; various elixirs including a cardiac tonic, luminal, compound senecio and viburnum; and a number of original mixtures and syrups.—[29] Wyleys, Ltd. (Coventry): among other pharmaceutical specialities, an emulsion of acetyl-salicylic acid, 5 grains to 1 drachm, pleasant to take and acting quickly, and a compound theocin mixture, containing 1 grain of theocin-sodium-acetate to the drachm.

A number of special pharmaceutical preparations were shown. [48] Armour and Co., Ltd. (Queen's House, Kingsway, London, W.C. 2): beef cubes, claimed to have a more intensive beef flavouring than any other cube on the market, and an exhibit of endocrines comprising tablets, capsules, powder and liquids, including a pituitary liquid prepared to a physiological standard.—[23] Crookes' Collosols (The Crookes Laboratories, 22, Chenies-street, London, W.C. 1): in additon to argentum, bromide, calcium, ferro-malt, iodine, kaolin, and sulphur in a colloid form, also collosol ichthyol in ointment and capsules, obtained solely from British shale.—[35] J. C. Eno, Ltd. (Victoria Embankment, London, E.C. 4): the well-known effervescent saline laxative, containing no crude mineral substance and free from sugar.—[51] Genatosan, Ltd. (Loughborough): nasmin, a germ-killing snuff; sanatogen, the well-known tonic food; formamint, to combat mouth and throat ailments; and a collection of detoxicated vaccines claimed to be 50 to 100 times less toxic than ordinary vaccines.—[53] Jeyes' Sanitary Compounds Co., Ltd. (64, Cannon-street, London, E.C. 4): preparations of cyllin, a non-irritant and non-caustic antiseptic with a Rideal-Walker coefficient for *B. typhosus* of 22 to 26; also a form of lysol (jeysol) for use when a clear solution in water is required.—[18] The Anglo-American Oil Co., Ltd. (Albert-street, Camden Town, London, N.W. 1): nujol, an intestinal lubricant manufactured to a standard viscosity, approved by clinical and chemical tests; and mistol, an oily solution for use in an atomiser along with camphor, menthol or eucalyptol.

Apart from the firms already mentioned, toilet preparations were shown by: [42] Kolynos, Incorporated (Chenies-street, London, W.C. 1): an antiseptic dental cream not interfering with the normal secretions of the mouth and free from grit.—[22] The Pepsodent Company (42, Southwark Bridge-road, London, S.E. 1): a dentifrice containing mildly acidic calcium salts stimulating the secretion of saliva; and the decoater tooth-brush designed for use therewith, in convenient pocket forms for travelling.

FOOD PREPARATIONS.

Foodstuffs and food accessories were represented by a large number of separate exhibits. [59] Cadbury Bros., Ltd. (Bournville, Birmingham): the usual exhibit of Bournville cocoa and chocolates, conforming to the highest standards of purity and uniformity.—[13] Food Education Society (329, Vauxhall Bridge-road, London, S.W. 1): publications on dietetics and hygiene, including The Gateway of Health, Facts for Patriots, Feeding of Children, Diet in Pregnancy, and a new pamphlet on Puddings and Porridge. The Society, which is undogmatic and philanthropic, sets out to educate the public in matters of food, cookery, and health.—[26] Food Products, Ltd. (11, Queen Victoria-street, London, E.C. 4): an exhibit of bovo-lactin in various forms, a product rich in assimilable animal protein, iron, and with a high vitamin content. Diluted with soda water it is recommended as a refreshing and stimulating drink for summer sports such as tennis.—[67] William Gaymer and Son, Ltd. (Attleborough, Norfolk): various brands of Gaymer's cyder, prepared from Norfolk apples, including the original "dry" brands which have received favourable medical comment.—[57] Glaxo (J. Nathan and Co., 56, Osnaburgh-street, London, N.W. 1): standardised dried milk products, including Prescription Glaxo, a new humanised form with a normal fat, low protein, and high carbohydrate content, particularly suitable in the early weeks of infant life and in cases of difficult assimilation, malnutrition, constipation, and so forth. When reconstituted with hot boiled water, 1 in 8, a milk is obtained with protein content as low as that of human milk—namely, 1·7 per cent. A report is available from a London hospital where since December, 1923, 15 infants have been fed upon it with satisfactory results. In no case did the milk cause vomiting, diarrhœa, or constipation, and in no case did the infants fail to gain in weight.—[45] Horlick's Malted Milk Co. (Slough): recommended as an ideal food from infancy to age, and as filling a useful place in Red Cross work for the ease with which it is prepared; also available in the form of food tablets.—[52] Milkal, Ltd. (31, St. Petersburgh-place, Bayswater, London, W. 2): a dried milk produced in a modern creamery from milk of Devonshire herds, under the supervision of inspectors, the drying being controlled by qualified chemists. The powder does not contain pathogenic organisms, and the number of other organisms remaining is low. It is claimed that there is hardly any coagulation of albumin, and that the calcium-casein balance is undisturbed.—[63] Numol, Ltd. (Newcastle-on-Tyne): a dietetic preparation containing malted carbohydrates, proteins, fat, lecithin, glycerophosphates, hypophosphites, diastase, and lemon; originally known in northern hospitals as "extractum nutriens," and containing 12·5 per cent. of animal fat. Also a non-irritant, non-poisonous antiseptic known as soloform, with the formula $C_6H_2I_3OH$, which can be used undiluted and is available in special form for immediate sterilisation of surgical instruments.—[30] Oxo, Ltd. (Thames House, Queen-street-place, E.C. 4): Oxo fluid beef, being a concentrated form of stimulating extractives together with easily digestible constituents of fresh, lean beef, seasoned ready for use, as well as Lemco, a pure unseasoned beef extract and beef essence for invalids and convalescents; also Oxoid brands of gland extracts, including thyroid, pituitary, and adrenal, in tablet form.—[33] Prideaux's Pure Casein Co., Ltd. (16, Southwark-street, London, E.C. 1): the Dorsella milk food, described as modified full-cream milk dried within a few hours of milking, with the addition only of lactose; half-cream milk powder for special prescription is also supplied. Casumen contains nearly 90 per cent. of casein and is completely free from starch and sugar.—[28] Virol, Ltd. (Hanger-lane, Ealing, London, W. 5): containing fats, carbohydrates, and proteins in well-balanced proportions and abundance of vitamins not destroyed in the process of manufacture; also virolax and the new virol and milk in golden powder, combining the properties of virol with full-cream Devonshire milk, and recommended for nervous and mental fatigue and for athletes in training.

MEDICINAL AND MINERAL WATERS.

[60] Bath (Mr. John Hatton, Director of Baths): an exhibit of photographs of the bathing establishments and water-colours of features of interest in and around Bath, with a special reference to the coming annual meeting of the Association at Bath in 1925.—[21] Droitwich (Mr. J. H. Hollyer, Joint General Manager of Bathing Establishments): a spa dependent for its therapeutic claims upon natural water only, the heavy brine constituting the strongest saline water known and facilitating the movements of immersed limbs; highly radio-active and radio-emanative.—[39] Harrogate (Mr. F. J. C. Broome, General Manager): unique in the diversity of its springs, with 87 waters each possessing distinctive characteristics, and under the supervision of a permanent scientific officer and analyst. The bathing equipment was visited by many members during the annual meeting of the Association.—[58] Ingram and Royle, Ltd. (45, Belvedere-road, London, S.E. 1): samples of imported natural mineral water, salts, and pastilles, including Vichy-Celestins, Contrexéville-Pavillon, Evian-Cachat, Hunyadi-János, Carlsbad sprudel salt, and 22 others.

MICROSCOPES AND SCIENTIFIC APPARATUS.

[19] Baird and Tatlock, London, Ltd. (14, Cross-street, Hatton Garden, London, E.C. 1): an impres-

ive exhibit of autoclaves, incubators, centrifuges, sterilisers, glass apparatus, stains, and media, including apparatus for determination of sugar in blood, Harris's air analysis, and an all-British Benedict metabolism apparatus.—[9] C. Baker (244, High Holborn, London, W.C. 1): a collection of microscopes and accessories to meet the needs of the student, advanced student, and research worker; also a new corneal magnifier and illuminator, with possible application to other clinical purposes.—[10] F. Davidson and Co. (29, Great Portland-street, London, W. 1): a variety of optical and electro-medical appliances and portable outfits for examination of the ear, nose, and throat, trans-illumination and cautery; also a new pharyngoscope on the principle of the cystoscope.—[7] Chas. Hearson and Co., Ltd. (47, Mortimer-street, London, W. 1): sole agents in Great Britain for Reichert microscopes and accessories; in addition to bacteriological apparatus, such physiological apparatus as kymographs, recording drums, respirator pumps, time-marking clocks, myographs, hæmocytometers, and so forth. This firm submits designs and carries out manufacture of apparatus for new experimental work.—[5] Kodak, Ltd. (Kingsway, London, W.C. 2): showing duplitised X ray films, positive prints on nikko-bromide paper, and reduced transparencies on Eastman commercial film; a series of very beautiful radiograms.—[62] Ronuk, Ltd. (Portslade, Sussex): materials and appliances employed in the preparation, initial polishing, and maintenance of floor and other interior woodwork by improved sanitary methods.—[65] Short and Mason, Ltd. (Aneroid Works, Walthamstow, London, E. 17): the Tycos sphygmomanometers, calibrated to standard readings and self-verifying.

Medical Agencies.

[1] The Medical Charities: Royal Medical Benevolent Fund and Epsom College.—[37] The Medical Insurance Agency (429, Strand, London, W.C. 2): founded in 1907 to persuade medical men to protect themselves by means of insurance against adverse fortune and unsatisfactory contracts, and to assist the medical charities.—[11] The Medical Sickness, Annuity, and Life Assurance Society, Ltd. (300, High Holborn, London, W.C. 1): founded in 1884 as a mutual society of medical and dental practitioners, with the object of obtaining sickness, accident, and life assurance on better terms than are offered by proprietary companies.

Books and Office Accessories.

[31] H. K. Lewis and Co., Ltd. (136, Gower-street, London, W.C. 1): an exhibit of new and important books in many branches of medicine, including those of the Cambridge University Press; additions to the stock of medical stationery—e.g., new cards for X ray treatment and electrical treatment in the card index system. The printed library catalogue has been kept up to date by two supplements, 1918–20 and 1921–23.—[16] The Oxford University Press (Warwick-square, London, E.C. 4): a set of the Oxford Medical Publications, comprising text-books and works on medical, surgical, and allied subjects, and several recent and important additions.—[12] Stanley Phillips (45, Brondesbury-road, London, N.W. 6): a collection of the latest publications of Messrs. F. A. Davis Co., Philadelphia, E. and S. Livingstone, Edinburgh, and Cassells, London: including the Practical Medicine Series of Year-books on general medicine, surgery, and special subjects.—[64] W. B. Saunders Company, Ltd. (9, Henrietta-street, London, W.C. 2): a number of new books and new editions, including Pædiatrics by 150 authorities: Operative Surgery, edited by W. S. Bickham, in four volumes, and other standard books.—[17] Tapp and Toothill, Ltd. (Bradford): a set of office indispensables, including the ingenious Bates rotary telephone index.—[41] John Wright and Sons, Ltd. (Bristol): a series of new publications, including Epidemic Encephalitis, by Prof. A. J. Hall; Diseases of the Nose, Throat and Ear, edited by Dr. A. Logan Turner; and new editions of standard medical works.

Corrigendum.—In our report of the Section of Ophthalmology (THE LANCET, August 9th, p. 295, col. 1, five lines from the bottom) the sentence should read: "The beam should be directed at a suitable angle so as to avoid the *specular reflection from the* corneal epithelium."

Correspondence.

"Audi alteram partem."

THE VIRUS OF FOOT-AND-MOUTH DISEASE.

To the Editor of THE LANCET.

SIR,—The photographs of the colonies and of the individual organisms of the virus of foot-and-mouth disease reproduced in THE LANCET of August 2nd will no doubt be of interest to many workers in bacteriology and allied sciences. In common with most English references to this recent discovery, the description you give is not quite accurate. The photo-micrographs have been obtained by using ultra-violet light as an illuminant, but the apparatus used is not the ultra-microscope as might be inferred from your article. An ordinary type of microscope was used, but it is fitted with objectives and condensers of quartz. The light source is provided by passing a high tension electric discharge between cadmium electrodes, the desired wave-length in the ultra-violet (275 μμ) being isolated spectroscopically.

No doubt the similarity of the terms "ultra-violet microscopy" and "ultra-microscopy" has led to some confusion, but the purpose of the two methods is widely different. The terms themselves are perhaps open to objection, but as they are in general use and are recognised by microscopists as applying to different branches of work, it is difficult to alter them. Any confusion in their use is probably due to failure to appreciate that there are two distinct microscopical methods. In one the aim is to obtain the utmost resolution, in the other to obtain the greatest visibility. Resolution is dependent on the wave-length of the light used and on the numerical aperture of the objective, whereas visibility is mainly dependent on the intensity of the illuminant. Resolution is the desideratum in all ordinary observational work with the microscope and the use of ultra-violet light comes within this category, although the image itself is invisible and has to be recorded photographically. The difference between the use of white light in which the dominant wave-length is of the order of (say) 550 μμ and ultra-violet light of wave-length 275 μμ, is that resolution is doubled, such increase of resolution proceeding regularly as the wave-length used is reduced. Thus objects of half the size of those seen by white light may be satisfactorily shown.

The organism of foot-and-mouth disease is presumably of the order of size that can be photographed in ultra-violet light (about 0·1 μ), while it would be impossible to resolve it by any method in which white light is used. The method has other and perhaps even greater advantages for biological work, as organisms do not require any preparation before being photographed; they can be dealt with in the living state. Now the ultra-microscope secures increased visibility, and there is no theoretical limit to the size of an isolated object that can be made visible by this means; it is in general merely a question of whether the object can be made sufficiently luminous to be seen. The light used is therefore of high intensity, usually an arc-light or sunlight, and illumination is at right-angles to the direction of observation. The image obtained of a small particle is a circular disc of light giving no indication of its shape or size. It follows, therefore, that this method is of limited application, and it is in practice confined to the observation of colloidal particles. The ordinary dark-ground illuminator is a particular form of this apparatus limited in its scope to the observation of objects within the resolving power of the objective used. The organism of foot-and-mouth disease could not, therefore, be identified by this method from inanimate particles of the same order of size. Indeed, there is no suggestion in the original papers by Frosch that the ultra-microscope has been used in the researches which have led to the discovery of the virus of foot-and-mouth disease.

I am, Sir, yours faithfully,

August 9th, 1924. J. E. Barnard.

INTOLERANCE TO A DENTURE.

To the Editor of The Lancet.

Sir,—In reply to Dr. H. St. A. Agate it is quite possible to have a narrow upper denture attached by springs to the lower. By this means the upper is maintained in position with nothing to irritate the palate.

I am, Sir, yours faithfully,

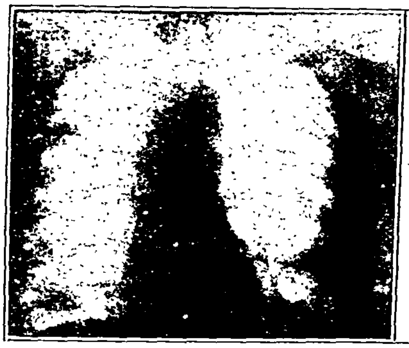
W. Rushton.

Harley-street, W., August 9th, 1924.

SELECTIVE COLLAPSE IN ARTIFICIAL PNEUMOTHORAX.

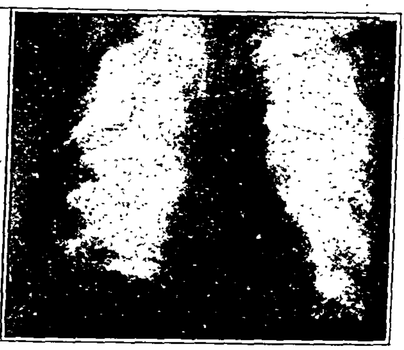
To the Editor of The Lancet.

Fig. 1.



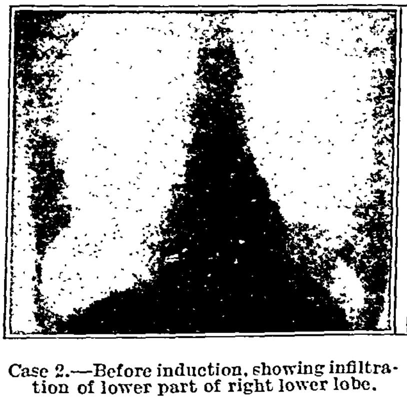
Case 1.—Before induction, showing infiltration of right upper lobe.

Fig. 2.



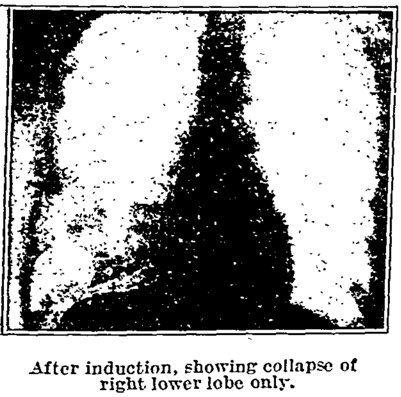
After induction, showing collapse of right upper lobe only.

Fig. 3.



Case 2.—Before induction, showing infiltration of lower part of right lower lobe.

Fig. 4.



After induction, showing collapse of right lower lobe only.

Sir,—In April, 1922, Nathan Barlow and David Kramer published in the *American Review of Tuberculosis* a preliminary report upon selective collapse under partial pneumothorax. They discussed what appeared to them to be some of the shortcomings and disadvantages of artificial pneumothorax treatment as it is practised to-day; and they also pointed out that if small quantities of air are introduced into a free pleural cavity containing a lung only partially infiltrated with tuberculosis, the air so introduced will tend to collect over or round the diseased areas only, collapsing these and leaving the rest of the lung expanded and capable of function.

The advantages to be gained, if this selective collapse is possible, are obvious. Barlow and Kramer set them out as follows: (1) Little or no general disturbance on induction; (2) little or no general disturbance during treatment; (3) less disturbance of function if the pneumothorax was to be discontinued for any reason; (4) great widening of the choice of cases suitable for artificial pneumothorax treatment; (5) the possibility of inducing bilateral artificial pneumothorax safely and without distress to the patient.

The method seems to point a way to the solution of one of the great difficulties in the treatment of pulmonary as distinct from other forms of tuberculosis—that is, of resting the diseased organ or its diseased part. As our knowledge stands at present there are still only a small proportion of cases suitable for collapse, but this method should tend to enlarge that proportion considerably. For this reason it would have been expected that the publication of this work would have aroused a great deal of interest among those who practise pneumothorax treatment, and it is because this does not appear to be the case that I am emboldened to publish the fact, that by following out the technique laid down in the original article I have, during the last two years, been able to confirm Barlow's and Kramer's results in general. Further, that small quantities of air carefully introduced into a relatively free pleural cavity will produce selective collapse of the diseased areas only, and that in suitable cases all the advantages claimed actually occur.

The method has not in my hands given 100 per cent. successes, but the results have been so very striking and encouraging that I have felt it worth while to spend a great deal of time in studying and practising it. I hope that this short account, with the accompanying illustrations, will be found sufficiently interesting to persuade my colleagues to give selective collapse a thorough investigation, so that its apparently great possibilities may be developed. As I have not modified or attempted to improve upon the original technique in any important details, I do not recapitulate it here, but refer those interested to the original article.

The plates show two typical cases before and after induction. In both the air was introduced in the same place—that is, between the fourth and fifth ribs in the mid-axillary line.

I am, Sir, yours faithfully,

R. C. Wingfield, M.B., B.Ch. Oxf.,
Medical Superintendent, Brompton Hospital Sanatorium, Frimley.

August 8th, 1924.

THE STROMA OF RED CORPUSCLES.

To the Editor of THE LANCET.

SIR,—For some years I have been treating cases of acute and chronic bacterial infections by a method based on the idea that the stroma of red corpuscles, when set free into the circulation by the destruction of the cell envelope, has toxic characters, and that this cellular endotoxin is a factor in disease. Briefly stated, the hypothesis is that in bacterial infections two factors have to be considered: firstly, the specific toxin which causes the manifestations of disease characteristic of the particular bacteria concerned, and secondly, a toxic substance set free from the red corpuscles by the hæmolytic properties possessed by most, if not all, pathogenic bacteria. In malaria I believe we have a disease in which the symptoms are due chiefly or entirely to this endotoxin, set free by the disruptive effect of the parasite on the red corpuscles. The aim of the method of treatment I have employed is to immunise the body against this endotoxin by using an emulsion of destroyed red cells as an antigen, exactly as a vaccine is used to set up immunity against a bacterial toxin.

The present state of the experimental evidence is as follows: (1) The subcutaneous injection of 1 c.cm. of a suspension of red cells destroyed by heat (56° C.) is followed by a local inflammatory reaction. No reaction follows the injection of unheated red cells. (2) C. J. Bond (*British Medical Journal*, Jan. 11th, 1919) has shown that red cells destroyed by grinding in a mortar are toxic to leucocytes, as shown by arrest of emigration of leucocytes and absence of iodophil reaction. (3) Washed red cells exposed to the rays of the tropical sun are rapidly destroyed and reduced to a granular débris, the glass container being kept immersed in water to eliminate the heat factor. These experiments were carried out in India in June, 1918; I have not been able to show any destructive effect on repeating the experiment in England. (4) Complement deviation tests to demonstrate the presence of an immune body in the serum after injection of destroyed red cells and in certain diseases have been carried out for me by Dr. W. W. Mackarell, pathologist to the Leicester Royal Infirmary; the results so far obtained, though suggestive, are not convincing. An acetone extract of washed red cells has been used as an antigen. Briefly, it may be stated that the serum of patients who had received a course of injections absorbed slightly more complement than serum from the same patients before the injections were begun. The serum of a patient suffering from malaria (benign tertian, before treatment with quinine) showed constantly a greater absorption of complement than any other serum tested.

I am anxious to obtain more experimental evidence in support of the toxicity of the stroma of red corpuscles at the hands of those who have more facilities than I have for animal experiment.

I am, Sir, yours faithfully,

Leicester, August 11th, 1924. T. C. CLARE.

TREATMENT OF ACUTE ANTERIOR POLIOMYELITIS.

To the Editor of THE LANCET.

SIR,—I read with much interest in your issue of July 26th Dr. Geoffrey Bourne's article on modern technique in the treatment of acute anterior poliomyelitis. My criticism of Dr. Bourne's treatment of this disease centres round the prominent place which he gives to massage as a curative agent, and the absence of prominence which he gives to active movements. Dr. Bourne, in my opinion, goes beyond any previous enthusiast for massage when he states that the mother is the most valuable ally in the campaign waged for recovery, and that massage is the weapon (to keep to the military metaphor) on which full reliance should be placed. The surprising statement is made that after two months the mother shoulders the whole burden, and full detailed instructions are given as to how this home massage should be carried out.

The treatment of infantile paralysis resolves itself essentially into recovery of normal motion. Any treatment of this disease must stand or fall by this test, and success can only be judged by the amount of movement obtained. Massage, in my opinion, is useless as a remedial agent for the recovery of muscle function; that is to say, it can neither initiate muscular movement nor can it increase its range or power. Massage has its function as a vasomotor stimulant, but beyond that I deny its efficiency in this disease. Dr. J. B. Mennell has stated (THE LANCET, 1924, i., 161) that "not infrequently, more harm than good is done by this treatment [i.e., massage] in cases of infantile paralysis," and again "massage assists the circulation . . . . but cannot possibly secure one single voluntary contraction."

Voluntary movement can only be initiated by the central nervous system, and gradually developed by systematic and carefully-graduated exercises. Dr. Bourne gives six lines of treatment to movements both active and passive, and would seem apparently to place very little dependence on them. In an article on "modern treatment" no mention is made of what is essentially a modern development—muscle re-education. This I consider to be modern treatment—all else is purely subsidiary treatment. In any question of the recovery of muscle function in a case of infantile paralysis it is essential to differentiate between the upper and lower limbs. An amount of movement may be obtained in the upper limbs quite sufficient to subserve good function, but the same range and amount of movement may be quite inadequate in the lower limbs, where, apart from motion, the question of weight bearing has to be considered.

In my opinion, much subsequent weakness and deformity would be prevented if strict instructions were given that no child with infantile paralysis of one or both lower limbs should be allowed to stand or walk until the expiry of 12 months at least from the onset of the disease.

I am, Sir, yours faithfully,

CHARLES MACKAY, M.D.

Wimpole-street, W., August 11th, 1924.

A BIBLIOGRAPHY OF SIR THOMAS BROWNE.

To the Editor of THE LANCET.

SIR,—The notice of Mr. Geoffrey Keynes's excellent bibliography of Sir Thomas Browne, which appeared in THE LANCET of August 9th, prompts me to ask whether a curious parallel between Browne and a writer of a very different calibre—namely, Charles Dickens—has been noticed. Both men are best known by their first book, written in their early years: in the case of Browne when he was 29, in the case of Dickens when he was 23. Again, the original MS. of Religio Medici is lost and so is the original MS. of Pickwick. Only MS. transcripts exist of the former work, of the latter a few leaves exist. Both works have been translated into various foreign languages; and the last and most striking similarity is that both works gave rise to a generous crop of imitations. The list of imitations of Religio Medici is given from No. 387 to 470*b* in Mr. Keynes's bibliography, while as for Pickwick it will suffice to mention "Pickwick Abroad," "Pickwick in India," and "The Queerfish Chronicles," among many others. Between no two books so dissimilar in date, matter, and style can, I think, the same similarities be traced.

I am, Sir, yours faithfully,

Forest Row, August 12th, 1924. H. P. CHOLMELEY.

THE LATE DR. H. L. HANNA.—At the inquest on Dr. Henry Lyle Hanna, who was killed as the result of an accident while driving a motor-car near Linzford, Newcastle, Mr. A. E. Boulton, deputy coroner, expressed his opinion that the cause of death was an accident pure and simple. At a dangerous turning of the road two tyres burst, and as Dr. Hanna swerved to avoid a ravine, the car overturned. By his action, the coroner stated, Dr. Hanna had saved the lives of the other occupants of the car. The deceased, who qualified M.B., Ch.B. Dublin in 1923, held an appointment at the Fleming Memorial Hospital for Children, Newcastle.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Summer Recess.

THE House of Commons adjourned on Thursday, August 7th, for the summer recess until Oct. 28th. A resolution was passed empowering the Speaker, after consultation with the Government, to cause the House to meet at any earlier time if thought necessary in the public interest. The House of Lords adjourned until Sept. 30th. The Royal Assent was given by Commission to a number of Acts, including the National Insurance Act and the Workmen's Compensation (Silicosis) Act.

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 6TH.

Local Authorities and Birth Control.

Mr. **THURTLE** asked the Minister of Health if new legislation was necessary before local authorities could be authorised to give information concerning birth control at maternity centres.—Mr. **WHEATLEY** replied: The question whether further legislation would be required is not free from doubt, but in any case, as I have already informed the hon. Member, I am not prepared to sanction the use of maternity centres for so controversial a purpose without express direction by Parliament.

Pensions Medical Officers and Overseas Service.

Lieut.-Colonel **FREMANTLE** asked the Minister of Pensions whether he was satisfied that, in selecting medical officers for discharge from his department, those who had not served overseas were discharged before those who, if equally efficient, had served overseas; and whether he was satisfied that no medical officer without overseas service was retained in a position for which an officer with overseas service was eligible and equally suitable.—Mr. F. O. **ROBERTS** replied: The answer to both parts of the question is in the affirmative, subject always to the paramount consideration of efficiency of the public service.

An Industrial Medical Service.

Captain **REGINALD TERRELL** asked the Secretary of State for the Home Department if it was the intention of the Government to establish an industrial medical service; and, if so, with what object.—Mr. **HENDERSON** replied: Provision is made in the Factories Bill for the amendment and extension of the existing system of medical examination of young persons for factory employment on the lines recommended in the report of the recent Departmental Committee (Cmd. 2135).

THURSDAY, AUGUST 7TH.

Male Inspectors of Physical Education.

Colonel Sir **CHARLES YATE** asked the President of the Board of Education how many male inspectors of physical education were now employed, and how many hours a week were devoted to the physical education of boys in elementary and secondary schools, respectively.—Mr. **CHARLES TREVELYAN** replied: There are at present one male staff inspector and two other male inspectors of physical training employed by the Board. Neither the code nor the regulations for secondary schools prescribe the number of hours in each week that thould be devoted to physical exercises. In public elementary schools the time varies, as a rule, from one to one and a half or two hours. In secondary schools one or two periods a week are generally given to physical exercises, in addition to any time given to organised games.

Health of the Unemployed.

Mr. **WILLIAM THORNE** asked the Minister of Health whether he had any information regarding the health of the unemployed men and women who had been out of employment for a lengthy period; and whether the percentage of illness of such men and women was higher than those persons regularly employed.—Mr. **WHEATLEY** replied: The expenditure by approved societies on sickness benefit under the National Health Insurance Acts affords some indication of the amount of sickness of all kinds amongst the insured population of the country, but the material in their possession does not make it possible to state whether the percentage of sickness is higher in the case of persons who have been out of employment for a lengthy period than in the case of persons regularly employed. Taking the insured population as a whole, there is no evidence that the prevalence of unemployment has adversely affected the claims for benefit under the Acts.

Medical News.

UNIVERSITY OF LONDON.—At a meeting of the Senate, held on July 23rd, the following teachers were recognised as teachers of the University, in the under-mentioned subjects: Mr. Frank B. Bull, orthodontics (Guy's Hospital); Mr. Frederick N. Doubleday, dental materia medica (Guy's Hospital); Mr. William K. Fry, dental prosthetics (Guy's Hospital); Mr. Frank J. Pearce, operative dental surgery (Guy's Hospital); and Dr. Ida S. MacLean, biochemistry (Lister Institute of Preventive Medicine).

St. Mary's Hospital Medical School.—The University scholarships at St. Mary's Hospital Medical School have been awarded to T. C. Hunt, Magdalen College, Oxford, and D. N. Rocyn-Jones, Downing College, Cambridge.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the Final Examination in Medicine, Surgery, and Midwifery, held during the month of July, the following candidates were approved in the subjects indicated, but are not eligible for diplomas:—

Medicine.—F. N. Adams, St. Bart.'s; C. Adamson, Cambridge and Durham; B. Adlington, King's Coll.; A. J. Amor, Middlesex; T. F. Anderson, Univ. Coll.; Doris M. Baker, St. Mary's; H. C. J. Ball and W. A. Barnes, St. Bart.'s; R. M. Barron, St. Thomas's; R. H. Bestawros, Cairo; Anna M. V. Bonhote, King's Coll.; W. A. Bourne, H. F. Brewer, and D. A. Brigg, St. Bart.'s; G. C. W. Brown, Cambridge and St. Bart.'s; E. Buchler, St. Bart.'s; P. Chandler, London; W. T. R. Chapman and F. W. Charman, King's Coll.; K. R. Chaudhri and Gwendoline Chave, St. Mary's; Florence C. Churcher, Univ. Coll.; S. Cieman, Guy's; A. H. F. Cole, Durham; Doris M. Collins, Royal Free; W. R. F. Collis and J. W. E. Cory, King's Coll.; A. C. Counsell, Middlesex; A. A. Dalby, Guy's; A. F. C. Davey, Manchester; A. L. Davies, Oxford and St. Thomas's; D. J. Davies, Middlesex; Kathleen Davies, Charing Cross; C. S. Drawmer, St. Bart.'s; W. A. D. Drummond, Dundee; G. D. Drury, St. Bart.'s; J. McM. Wilder, London; D. P. Williams and E. C. P. Williams, Middlesex; J. H. Williams, London; W. B. Williams, Charing Cross; D. A. Wilson, Middlesex; N. Wilson, Univ. Coll.; Ellen Wirtz, Royal Free; J. T. Woodhead, St. George's; C. L. Worthington, Guy's; and E. W. C. Woutersz, St. Mary's.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL. The Goldsmid Entrance Exhibitions for 1924 have been awarded to Mr. C. L. Owen, Trin. Coll., Cambridge; and Miss F. C. Kelly, Univ. Coll., London.

Bethlem Royal Hospital has been admitted as a school of the University of London in the faculty of medicine for the purpose of research in psychological medicine.

UNIVERSITY OF PARIS.—Post-graduate courses on dermatology and venereal diseases, commencing respectively on Oct. 3rd and Nov. 5th, 1924, will be held at the Clinique de Dermatologie et de Syphiligraphie of the Hôpital St. Louis, Paris, under the direction of Prof. Jeanselme. The fee for each course is Fr.150. A detailed programme and all further particulars may be obtained from Mr. Burnier, Chef du Clinique à la Faculté, Hôpital St. Louis (pavillon Bazin), 40, Rue Bichat, Paris (X^{ième}).

MIDDLESEX HOSPITAL MEDICAL SCHOOL, LONDON.—The introductory address at the opening of the winter session 1924–25, on Oct. 1st, will be delivered at 3 P.M. at the Queen's Hall by Dr. Charles Porter, on Some Aspects of Preventive Medicine, after which the prizes gained during the previous year will be distributed by the Earl of Birkenhead. In the evening, at 7.30, the annual dinner will be held at the Hotel Cecil, when Mr. G. Gordon-Taylor, M.S., F.R.C.S., will preside. Those wishing to be present at the dinner should communicate as soon as possible with the Secretary-Superintendent of the hospital.

ARTIFICIAL HELIOTHERAPY.—Recently the Hull Corporation authorised the maternity and child welfare committee to establish an experimental sunshine clinic for the administration of artificial heliotherapy to ailing and rickety children under 10 years of age.

Messrs. W. Heffer and Sons, Ltd., announce the early appearance of Practical Physical and Colloid Chemistry for Students of Biology and Medicine, by Prof. Leonor Michaelis, of Berlin, translated from the second German edition by T. R. Parsons, M.A., B.Sc., demonstrator in physiology in the University of Cambridge.

THE Kent County Council, at their quarterly meeting, held on August 6th, decided unanimously to increase the salary of their county medical officer, Dr. Alfred Greenwood, from £1400 to £1600, without any application having been made by that officer.

THE annual report for 1923 of the Chief Medical Officer of the Ministry of Health, shortly to be issued to the public, is 211 pages in length, including four short appendices, and may be obtained either direct from H.M. Stationery Office or through any bookseller, price 3*s*.

COTTON-SPINNERS' CANCER.—Following on the ruling of Judge Mossop in the test case before the Ashton under-Lyne County Court (see THE LANCET, August 2nd p. 239), where compensation was awarded to an operative mule-spinner who had contracted epithelioma of the scrotum in the course of his employment, an Oldham mill company has been served with a claim for compensation under the Workmen's Insurance Act. The case is that of a cotton-spinner who has been dead for two years, and who ceased his connexion with spinning eight years before his death.

THE LATE DR. R. A. WILLIAMS.—Dr. Robert Arthur Williams, who died recently at his residence at Porthcawl, was one of the oldest medical practitioners in South Wales and was well-known throughout Glamorgan. A native of Carnarvon, he was 74 years of age, and had been in general practice for nearly 43 years, 28 of which were spent at Ogmore Vale. He will be remembered by his many friends and patients, who had for him a great admiration as one of the rescue party in the Park Slip Colliery explosion, which occurred some 30 years ago and in which he nearly lost his life. Dr. Williams, who was one of the senior magistrates of the county, was a graduate of Edinburgh University, having qualified M.B., C.M. in 1882. He leaves a widow, one son, and two daughters.

DONATIONS AND BEQUESTS.—Under the will of the late Alderman G. Macpherson, of Wolverhampton, the testator left, among other bequests, £250 to the Royal Orthopædic and Spinal Hospital, Birmingham; £250 to the Royal Orphanage, Wolverhampton; £250 to the Wolverhampton and Midland Counties Eye Infirmary; and £250 to the Wolverhampton and Staffordshire General Hospital. Failing certain family trusts, he left £5000 to the Royal Orthopædic and Spinal Hospital, Birmingham; £5000 to the Royal Orphanage, Wolverhampton; £5000 to the Wolverhampton and Midland Counties Eye Infirmary; £5000 to the Wolverhampton and Staffordshire General Hospital; and the ultimate residue to the British Red Cross Society and/or such other societies, hospitals or institutions as may have been founded or established for the relief, cure, care, maintenance or support of wounded and disabled or blinded soldiers and sailors.—By the will of the late Mrs. Mary Frances Thorne, of Dunconusg, Lossiemouth, N.B., and of Heckfield, Hants, the testatrix left £1000 to the London Hospital, Whitechapel, for the maintenance of the "Maggie's Bed," and £1000 to the Royal Free Hospital, Gray's Inn-road, for the maintenance of the "Augustus Thorne" Bed.—The late Mrs. Louisa Walker, of Leytonstone, Essex, left by will £500 each to the London Hospital and the Poplar Hospital for Accidents.—By will the late Mrs. Camilla Anna Olympia Bertie-Roberts, of Chelsea left, among other bequests, £2000 equally between the Chelsea Hospital for Women, the Victoria Hospital for Children, the West End Hospital for Nervous Diseases, the Ophthalmic Hospital, the Normal School of Music for the Blind, and the Seamen's Hospital, Greenwich, and £100 to the Home for Disabled Soldiers and Sailors as well as £50 to the Home for the Dying, Mare-street, Hackney.—Among other bequests, the late Mr. G. M. Henton, of Leicester, left by will £1000 to the Leicester Infirmary.—The late Mrs. Emma Hinchliffe, of Upper Norwood, bequeathed by will £2000 to the Hospital for Sick Children, Great Ormond-street, in memory of her husband, Walter Hinchliffe; £1000 each to the Sunshine House Blind Babies' Home, Chorley Wood, the Westminster Hospital, the Cancer Hospital, Fulham-road, the Home for Incurables, Streatham, and the Home for Incurables, Putney; and (after personal bequests) all other her property "to the hospitals named above, especially those for children."

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 18th.—11 A.M., Surgical Registrar: Surgical Wards. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

TUESDAY.—12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks Davis: Throat, Nose, and Ear Operations.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, August 18th, to SATURDAY, August 23rd.—THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. Mon., 10 A.M., Dr. Burrell: Demonstration of Cases illustrating Protein Tests and Treatment of Asthma. 12 noon, Dr. Beaumont: Demonstration of Cases. 2 P.M., Dr. Melville: Demonstration in X Ray Department. Tues., 10.30 A.M., Dr. Punch: Demonstration of Morbid Anatomy. 11.30 A.M., Dr. Davidson: Demonstration of Cases. Wed., 10.30 A.M., Mr. Tudor Edwards: Operations. 2 P.M., Dr. Gosse: Demonstration in Wards. Thurs., 10 A.M., Dr. Burrell: Artificial Pneumothorax and Thoracoscopy. 12 noon, Dr. Beaumont: Demonstration of Cases. Fri., 10 A.M., Dr. Davidson: Demonstration of Cases. 11 A.M., Dr. Nelson: Artificial Pneumothorax. 2 P.M., Mr. J. E. H. Roberts: Operations. Sat., 11 A.M., Dr. Batty Shaw: Demonstration of Cases.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E. Mon., 10 A.M., Mr. Broster: Cases illustrating General Surgery. 2 P.M., Mr. Nesfield: Conjunctivitis, Corneal Ulcer, Corneal Opacity. 4.30 P.M., Mr. Kenneth Lees: Demonstration on Mastoid Operation. Tues., 11 A.M., Mr. Kenneth Lees: A Practical Demonstration on Tonsillectomy. 2 P.M., Dr. King: Medical Cases. Wed., 10 A.M., Mr. Todd: Cases illustrating Orthopædic Principles. 2 P.M., Mr. Nesfield: Squint and its Treatment; Some Points in Refraction in Children; The Blindness of One Eye in Children. Thurs., 10 A.M., Dr. Winnicott: Medical Cases. 2 P.M., Mr. Whitchurch Howell: Demonstration of Surgical Cases, chiefly Orthopædic. Fri., 10 A.M., Mr. Broster: Cases illustrating General Surgery. 3.30 P.M., Mr. N. C. Lake: Surgical Treatment of Hypertrophic Stenosis. Sat., 10 A.M., Mr. Whitchurch Howell: Operations.

Appointments.

ADAM, J., M.B., C.M. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Handsworth District of the county of York.

DORWARD, W. F., M.B., Ch.B. St. And., Superintendent of the St. Luke's Hospital at Haifa under the Jerusalem and the East Mission.

MERCER, L. D., M.B., Ch.M. Sydney, F.R.C.S. Edin., Honorary Assistant Surgeon for Diseases of the Ear, Nose, and Throat, Salford Royal Hospital.

PLATT, H., M.D., M.S., F.R.C.S. Eng., Consulting Orthopædic Surgeon to the Lancashire Education Committee.

SMITH, N. ROSS, F.R.C.S. Eng., Resident Medical Officer to the Freemasons Hospital and Nursing Home, Chelsea.

Vacancies.

For further information refer to the advertisement columns.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each £200.

Brighton, New Sussex Hospital.—H.S. £50.

Bristol General Hospital.—Two H.P.s, two H.S.'s, Res. Obstet. O., and Cas. H.S. Each £80.

Bristol Royal Infirmary.—Cas. H.S., Obstet. and Ophth. H.S. Each £100. H.P.'s and H.S.'s and Asst. Obstet. H.S. Each £80. Also Dental H.S. £116.

Bromley Borough.—Temp. Asst. M.O.H. £600.
